Dr. Bernardy did not think the instrument necessary. The proper-sized pessary can be estimated by an experienced practitioner, and if the first one inserted is not a good fit he would scarcely fail with the second. He did not believe in multiplying instruments unnecessarily. The less instrumental interference is resorted to, the better it will be for physician and patient.

In reply to a question, the President said that in ordinary cases he preferred a modifi-

cation of the Hodge pessary. In anteversion, however, he uses the double lever pessary of Thomas.

FOREIGN SUBSTANCE IN FECAL DISCHARGES.

Dr. A. Schapringer exhibited some peculiar material passed by a child ten years old and found in the stools. When first seen, they were like the pits or part of the pulp of an orange, and were evidently of vegetable nature. He recalled the fact that during the Franco-Prussian war a woman had passed similar substances, which were ascertained by Virchow to be orange-pulp.

IMPROVED HYPODERMIC SYRINGE, WITH REMARKS ON PELLETS FOR HYPODERMIC USE.

Dr. R. S. Huidekoper exhibited an improvement of the hypodermic syringe, having a small chamber at its upper extremity, capable of containing eight or ten pellets of morphia (gr. $\frac{1}{8}$ to gr. $\frac{1}{4}$ each). The entire apparatus was compact, and easily carried in the vest-pocket.

Dr. H. A. Wilson approved the plan proposed, and exhibited his small case containing a hypodermic syringe, and several glass tubes, with a diaphragm in the middle of each so as to enable them to hold a different variety of pellets in each end. He referred again to the advantages of the pellets over the ordinary solutions, especially Magendie's solution, which now is very seldom used, and requested the President to state his opinion.

Dr. Albert H. Smith said that he had not had much experience with the pellets for hypodermic use, but that it appeared to him that it would be impossible to secure as accurate dosage by this means as in the form of solution. In gynæcological surgery he uses the mixed anæsthesia, as recommended by Nussbaum, Bernard, and, more lately, by Dr. Reeve, of Dayton, giving a hypodermic injection of morphia (gr. $\frac{1}{4}$), previously to administering the ether, as by this method the stage of excitement is bridged over and less of the anæsthetic is required. In a recent case for some gynæcological operation he had used one of these quarter-grain pellets, as recommended by Dr. Wilson, instead of the usual Magendie's solution. After the completion of the operation, and etherization had been concluded, he was surprised to find that the patient did not recover consciousness, but, on the contrary, seemed sinking into coma. Respiration fell to four or six in the minute, the pulse was thready and slow, the pupils almost invisible: she had, indeed, every symptom of extreme morphia-poisoning, from which she was only recovered with great difficulty. He could only ascribe the results to an overdose of morphia, as the patient had been etherized before without any such manifestation. The accident suggested some inaccuracy in the subdivision of the morphia in the pellets. He had always used Magendie's solution of morphia, which allowed very little danger of mistake; but the preparation of the pellets requires very careful manipulation to avoid error.

In reply to a question, he stated further that the operation had lasted about an hour and five minutes. He could not remember the amount of ether used, but it was not excessive. It required prolonged efforts at resuscitation, with artificial respiration, injections of coffee, and warmth and friction to the extremities. He was not aware that the patient was particularly susceptible to morphia.

Dr. H. A. Wilson said that the sample used by the President probably belonged to the first that were made. The pellets are manufactured by Dr. Wolff with extreme care; the muriate of morphia is first weighed out in quantities of two to four grains, into which the proper proportion of atropia in solution is placed, and thoroughly mixed; the powder is then dried, and weighed out into quarter-grain or smaller powders, the sodium chloride added, and the whole compressed. By pursuing this careful manipulation error seems to be impossible. He believed that if one of these later pellets was used, the accident in the case mentioned must be referred to idiosyncrasy or other circumstances. He recalled a case in which he had given one-twelfth of a grain hypodermically and produced all the symptoms of severe morphia-poisoning. He condemned the ordinary solutions of morphia, on account of the rapid development of a fungus, which destroys the alkaloid, so that after it has been kept some time it becomes worthless.

Dr. F. Woodbury said that he had not tried the pellets, but they appeared to present a convenient form for use, and had some advantages. As regards stability, however, it still remains to be proved that these pellets are more permanent than the solutions which they are intended to supplant: they are certainly deliquescent to some extent, on account of the sodium chloride, which has great affinity for water; nor is it to be forgotten that under such circumstances the alkaloid might become exposed to the action of nascent chlorine, and thus undergo destruction like ordinary organic matter. Whether they are permanent or not in fact is to be determined by experience rather than by theory.

The speaker could not agree with Dr. Wilson that there was such universal dissatisfaction with the form of solution for the administration of alkaloids. When fractional doses are to be administered, it is a physical fact that cannot be gainsaid, that the solution affords the only absolutely accurate method of subdividing the medicament, and for this purpose the form of solution will probably always be retained. It is not improbable, however, that the convenience of the pellets may also give them a certain range of application, the two forms coexisting, each being

useful within its own limits: the question to be decided by experience is under what circumstances to use the solution, and under what other circumstances to prefer the form of pellets. He had also some doubt as to whether morphia solutions deteriorated so much by the development of the fungus *penicillium glaucum*. His observation had led him to believe that these alkaloid solutions really get stronger by keeping, from evaporation of the water; and the development of the parasite, even if at the expense of the alkaloid, thus only serves to keep the solution at a proper strength. He could say very positively that he had used such a solution which had been kept more than a year, and found it active in the usual dose.

Dr. Bernardy understood a former speaker to say that Magendie's solution is now very seldom used, which is opposed to the facts: indeed, in some parts of the country the officinal solution is not kept on hand by the apothecaries at all. While at a watering-place on Long Island last year, he had prescribed for a lady a drachm of solution of morphia, and the druggist put up Magendie's solution: he was told subsequently that this solution (gr. 16) was the only one kept by druggists on Long Island. In regard to its deterioration upon keeping, he doubted the fact. Having an attack of lumbago one night, and finding his ordinary powders had run out, he remembered a small bottle of solution of morphia, which had not been disturbed for at least eighteen months; it had been cloudy with fungus, which had settled to the bottom. He used this old solution hypodermically in ordinary dose, and found it physiologically active. He agreed with the last speaker that the small doses are more accurately divided when the drug is in the form of solution.

MODIFIED VOLSELLA FOR TONSILLOTOMY.

Dr. A. Schapringer exhibited a volsella forceps, with the prongs bent at an angle of forty-five degrees with the handles, for use in tonsillotomy. This instrument is much cheaper than the guillotine tonsillitome, and is easier to clean; the position of the prongs also enables the operator to take hold of the tonsils better than with the ordinary volsella which is commonly used.

Dr. John G. Packard did not know that any one in this country or any other country used any instrument but Physick's guillotine for the operation in question.

Dr. H. A. Wilson said that the instrument was very little different from those in use. Prof. Gross uses the volsella, and prefers it to the guillotine, especially where the gland is much hypertrophied.

Dr. Schapringer said that the modification was very slight. Its advantages, however, were so obvious that he had been surprised that it had not occurred to some one else. The instrument exhibited he had had made for his own use in 1863.

REPORT OF THE "COMMITTEE ON HYGIENE AND THE RELATIONS OF THE PROFESSION TO THE PUBLIC"—"ON THE RESPECTIVE DUTIES OF THE DRUGGIST AND PHYSICIAN."

Made to the Philadelphia County Medical Society, January 12, 1881.

"THE Committee on Hygiene and the Relations of the Profession to the Public" respectfully report as follows:

Dr. Geo. B. H. Swayze, having recently read before this Society a paper in which was discussed the injury done to physicians by certain practices of druggists to whom had been intrusted the dispensing of the prescriptions of medical men, the statements contained in his paper and the opinions elicited in its discussion led to the presentation before the Society of several resolutions designed to remedy the evils complained of. As these resolutions, with the consideration of the whole subject as discussed, were referred to the "Committee on Hygiene and the Relations of the Profession to the Public," they accordingly met for deliberation. At this meeting a report of the recent meetings of the Medico-Legal Society of this city, in which the same subject had been discussed, and also the comments of the *American Journal of Pharmacy*, Chicago *Pharmacist*, and *Pharmaceutical Journal* of London, November 23, on this subject, were fully presented. From these sources, with the paper of Dr. Swayze, the resolutions of the Society referred to your committee, and the personal evidence of members who were before the committee, it appeared that there were three special grievances laid at the door of the pharmacists:

First. That prescriptions sent to the shop of the druggist were renewed indefinitely, though the intention of the physician was that they should be filled but once.

Second. That druggists invaded the domain of the physician, by themselves prescribing for the sick instead of awaiting the prescription of the physician.

Third. That druggists were active agents in disseminating proprietary medicines and nostrums.

It seemed wise to your committee to bring these grievances formally to the notice of the Philadelphia College of Pharmacy, as a representative of the interests of pharmacy, and to ask a conference with that organization with a view to such a mutual understanding between representative physicians and druggists as might dissipate all difficulties. In reply to this request of your committee, the trustees of the Philadelphia College of Pharmacy appointed a committee to confer with your committee. (A copy of the minutes of this conference, at which Messrs. Remington, Taylor, Shinn, and Bullock represented the Philadelphia College of Pharmacy, is appended to this report, and to this is added a letter from Mr. Blair covering the whole subject.) As an

outcome of the discussion, the druggists claiming that they were placed in a false position by the silence of the physician, he not specifically stating that his prescription was to be filled but once, the following resolution was adopted by the committee of conference, and its substance is presented for acceptance to the Society:

"*Resolved*, That it is the sense of this 'Committee of Conference,' in order as far as possible to prevent the repetition of abuses that have arisen from the unauthorized renewals of prescriptions, that physicians be requested to write the words 'not to be renewed,' or words or symbols to the same effect, on prescriptions which they do not wish to be renewed without special orders; at the same time instructing patients in regard to the evils likely to arise from such renewals, and informing them of their wishes."

With reference to the prescribing by druggists, Mr. Taylor, on the part of the pharmacists, read the following from the Code of Ethics of the Philadelphia College of Pharmacy:

" . . . As the diagnosis and treatment of disease belongs to the province of a distinct profession, and as a pharmaceutical education does not qualify the graduate for those responsible offices, we should, where it is practicable, refer applicants for medical aid to a regular physician."

As this injunction of the pharmaceutical ethics, if carried out, would meet the question of prescribing by druggists, it was adopted as expressing the sense of the committee in the premises.

In reference to the sale of proprietary medicines, Mr. Taylor, on the part of the pharmacists, read the following from the Code of Ethics of the College of Pharmacy:

"Whilst the College does not at present feel authorized to require its members to abandon the sale of secret or quack medicines, they earnestly recommend the propriety of discouraging their employment when called upon for an opinion as to their merits."

This also was adopted as the sense of the committee of conference, and it is suggested that the Philadelphia County Medical Society approve the expression of the sentiments contained in the extract cited.

The conclusion which your committee has drawn from the above conference is that the interests of the medical profession are safe in the hands of reputable pharmacists, or such as govern themselves according to the excellent Code of Ethics of the Philadelphia College of Pharmacy. But it seemed equally true to your committee that, among the thousands who keep drug-stores and dispense medicines in Philadelphia, there are many who are guilty of some one or all of the offences charged against druggists: so that your committee offer the following resolutions:

"*Resolved*, That, in the opinion of the Philadelphia County Medical Society, a druggist acts simply as the *agent* of a physician in compounding his prescriptions, and that it is a breach of his proper obligations to the physician, to renew, without his direction, or furnish copies of, any formula prescribed.

"*Resolved*, That the members of this Society will note which druggists commit such breaches of obligations, and dissuade their patients from taking prescriptions to them to be compounded.

"*Resolved*, That the members of this Society will endeavor to have their prescriptions compounded by apothecaries who do not exhibit signs or circulars, or otherwise encourage the use by the public, of patented or proprietary medicines."

Inasmuch as it appeared that many physicians themselves prescribed patented and proprietary articles, it was further

"*Resolved*, That it be recommended to this Society to reaffirm the sentiments expressed in Section 3, Article I., of the By-laws of the Philadelphia County Medical Society,—viz., 'that any physician who shall enter into an agreement with an apothecary to receive pecuniary compensation or patronage for sending prescriptions to said apothecary, or who prescribes a remedy without knowing its composition, or who shall hereafter give a certificate in favor of a patent remedy or instrument, shall be disqualified from becoming or remaining a member of this Society.'

"*Resolved*, That this Society transmit to the trustees of the Philadelphia College of Pharmacy a copy of this By-law; also their approval of the sentiments contained in the articles of the Pharmaceutical Code of Ethics, above quoted."

Finally, your committee offer the following resolutions for the acceptance of the Society:

"*Resolved*, That the report of the committee be printed in full in the 'Transactions of the Philadelphia County Medical Society,' with the action of the Society, and that their publication be asked for, also, in the *American Journal of Pharmacy* and in the *Druggists' Circular*.

"*Resolved*, That the committee be discharged from the further consideration of the subject."

It was also

"*Resolved*, That the trustees of the Philadelphia College of Pharmacy be requested to furnish each of their graduates with a copy of the Pharmaceutical Code of Ethics."

It was also

"*Resolved*, as the sense of this Society, that there is nothing in Ethics to forbid a physician dispensing his own medicines."

By order of the committee.

RICHARD A. CLEEMANN,
Chairman of the Committee on Hygiene, etc.,
Philadelphia County Medical Society.

REVIEWS AND BOOK NOTICES.

FEVER. A STUDY IN MORBID AND NORMAL PHYSIOLOGY. By H. C. WOOD, A.M., M.D. Philadelphia, J. B. Lippincott & Co.,* 1881.

The growth of physiological research in America has been so slow that the appearance of a paper as ambitious as the one under review is an exceptional matter. We have at Harvard and at Johns Hopkins well-fitted, and in the latter place well-endowed, laboratories, but, so far, the most notable researches, and probably the most numerous as well as important, have come from men altogether without the advantages of good laboratories and the backing of plentiful means. The present essay is only one more illustration of the superior value of individual energy.

Dr. Wood had already written authoritative papers on thermal fever and the causes of fevers, and was thus led by degrees to make the vast and difficult study which now adds another valuable treatise to the many for which we are indebted to the liberal views of the managers of Smithson's foundation.

It is now several years since three men devoted themselves to the research which this volume chronicles. Two of them are dead, —Dr. Hare and Dr. Lautenbach,—and both have left behind them enough of good work to show how fair a future was lost to them. The labor thus begun has fallen for its completion altogether upon Professor Wood.

The essay is in four chapters. The essential symptom of fever is discussed in the first, and decided to be elevation of temperature: so that a natural history of fever can be had by causing it artificially through any means which gives rise to absolute increase in the animal heat. These experiments are part of Dr. Wood's essay identifying sunstroke as a thermal fever due purely to elevation of bodily temperature. The proofs of this and of the value of the use of cold as a remedy are strikingly re-stated and re-supported. Next arise for answer two questions,—What is the mechanism by which the production and dissipation of animal heat are regulated in the animal organism? Is the rise of temperature in fever due to the excessive retention or to the abnormal production of heat, or to these conjointly? And to answer these queries two long chapters are devoted.

Nothing but a careful and elaborate analysis of the hypotheses formed, of the experiments which test them, and of the conclusions reached, would do justice to this elaborate study. Save from a few of the higher students of physiology, it is unlikely that this portion of Dr. Wood's work will secure the careful attention it deserves. The only true and valuable criticism of a research so profound is to be looked for from such future experimental examinations as shall, in the hands of observers of equal force, determine the correctness of Dr. Wood's work.

In this necessarily too brief notice of what needs and deserves a full and careful review, it is, of course, impossible to describe in even a condensed form the groups of experiments, the minor inferences, the logical outcomes, and the testing of the value of one experiment or of sets of such acquired facts by others. It will, perhaps, suffice to say that, criticised from the stand-point of an old laboratory-working physiologist, the quality of Dr. Wood's work seems to me of rare excellence, and I can only regret that neither my own time nor the space here given me enables me so to analyze it as to make clear to others the strong grounds for my opinion.

On page 254 Dr. Wood states the attained facts of his own and of others' getting which enable him to state as a final conclusion what he now rests on as the theory of fever.

The facts so given will bear at least analytic statement. Their importance in relation to health, to fever states, to the therapeutics of disease and wounds, is simply enormous.

1. There is a normal range of temperature, and any disturbing causes which carry it outside of its usual limits constitute, in greater or less degree, ill health. The minimum is at 7 A.M., the maximum at 9 P.M. Fever follows a like law. The causes of these timed variations in normal and disease phenomena must have some relation to the external laws of nature, since the most profound perturbing influences —such as starvation—do not change them. One would like to know whether reversing natural habits, as by working at night and sleeping in the day, would have any influence on these phenomena. The subject is tempting enough. Why should 9 P.M. be the time of maximum body-heat? and is it so in all climates?

2. The nervous system controls the normal heat and the normal limits of heat, and *within certain* limits controls both the making and the dissipation of animal heat. The vaso-motor nerves, inclusive of the secretion nerves, chiefly control heat-loss in man: *i.e.*, by contracting the capillaries of the skin and lessening secretions, they reduce heat-loss, or, by reverse processes, increase it.

Outside of this governing and modifying influence, Dr. Wood believes in an inhibitory heat-centre which acts through spinal centres, but may be—and this seems still in doubt—a muscular vaso-motor centre, not purely endowed with power to control, irrespective of muscular action and muscle-nutrition, the extra-muscular sources of heat. Dr. Wood's experiments as to the place of heat-centres are perhaps the most interesting in his book. He thinks they may probably be referred to the pons, and are not in the cortex cerebri.

Fever he describes as a nutritive disturbance, with an elevation of temperature, and with increased chemical action in accumulated

* Reprinted, by permission, from the stereotype plates of the Smithsonian Institute.

tissue-matter of the body. As little food is taken or absorbed, this increase of heat is sometimes enough, sometimes not enough, to compensate for the loss of heat which usually is derived from the destruction of the surplus food in the body.

The fever-rise in temperature cannot, therefore, depend solely on increased heat-product, since in fever less heat is sometimes produced than at other times when the temperature is normal. Also, great heat-product at cost of the accumulated material of the body may occur without elevation of the thermometer. In fever vaso-motor palsy causes a fall of temperature similar to but greater than that produced by a like disturbance in health. Section of the cord also causes greater lessening of heat-product than in health. The so-called inhibition centre seems to be feeble in fever, but not paralyzed.

In all or nearly all serious fever Dr. Wood thinks there is a definite poison circulating in the blood. If, he says, we believe this to be so, our creed would be: fever is due to a poison, formed within or gotten from without, acting as a depressant on such nerve-centres as regulate production and dissipation of heat. The poison, or possibly a peripheral irritation, partially palsies the inhibitory centre,—so that, the brake being off, the machine goes at speed; or, more plainly, tissue-changes increase, more heat, of course, results, and the secretions abound in the melted and dissolved wrecks of fast-disintegrating tissues. Usually, as Dr. Wood believes, the normal rises in temperature act on the vaso-motor centres so as to produce through them automatic changes in the vessels which give rise to increased dissipation of heat; but in fever these centres, like all others, we presume, fail of their function, so that, until the temperature rises enough to become potent as a stimulus to paretic nerve-cells, there is a failure in the mechanism for dispersing or dissipating heat.

This theoretic conclusion covers most of the facts, and seems to be reasonable enough, and fairly made out on the authority of the facts and experiments related.

The local fever which in a limb follows nerve-section still remains without the thorough examination it needs. We cut nerves, the limb becomes hot, and so remains for days; its temperature may even rise six or seven degrees. What changes occur in the limited tissues so warmed? How do muscle and bone differ from those of the other side when such heat-product has been long kept up? Why, finally, does the heat fall below the normal? None of the nerve-section experiments have included division of the vaso-motor filaments which run with the vessels, and which could be interrupted by tight temporary ligatures of the vessels. Nor do we know whether galvanization of the peripheral trunk of a cut nerve will reduce the local fever. It would seem as though this might be a simpler method of studying at least some of the conditions of fever.

Prof. Wood is to be congratulated on the completion of a very remarkable labor, and the University of Pennsylvania upon such a product of its unendowed and ill-furnished laboratory of physiology.

S. Weir Mitchell.

GLEANINGS FROM EXCHANGES.

Headaches dependent on Disease of the Dura Mater.—Dr. J. S. Jewell, in an article on the nature and treatment of headaches (*Journal of Nervous and Mental Diseases*, vol. vi., 1881, p. 64), says that headaches depending upon acute, but much more frequently subacute, forms of disease of the dura mater are much more common than is ordinarily supposed. Affections of the dura due to blows, etc., and which are accompanied by pain, may occur suddenly, or after months, or even years. Tubercular deposits, rheumatic and syphilitic influence, may also give rise to pain in the dura. It sometimes follows in the wake of sunstroke or severe exposure to cold, or arises from the extension of disease from the nasal to the cranial cavity through the cribriform plate of the ethmoid bone, or from the middle ear, as in otitis media, also from unknown causes in cerebro-spinal meningitis. In addition to these, diseases of the bones, or tumors or growths, may lead to painful affections of the dura. Also, diseases of the Pacchionian bodies, or of the brain itself, may lead to affections of the dura of a painful nature. The inflammations of this membrane are ordinarily localized rather than general. Painful affections of the dura may occur at any age, but are commoner during later childhood, youth, and the middle period of life.

With regard to the symptoms, the pain is usually definitely localized. It does not shift from place to place, as it does in many of the circumscribed pains of neuralgia; it is persistent, seldom entirely ceasing long at a time so long as the meningitis continues; it commonly begins gradually and disappears slowly; it is aggravated by anything which increases the activity of the intercranial circulation; it is aggravated by shocks to the head; it is not relieved in assuming the lying-down position. As a rule, it is made worse by increased barometric pressure and by the occurrence of cold weather, or by exposures of the surface to cold by which the cutaneous vessels are contracted, or by any other means by which vascular tension is increased, or by any means by which the cutaneous circulation is diminished in activity or repressed. It occasionally throbs when the heart's activity is increased. It is accompanied generally by more or less mental depression and by ner-

vous irritability, discouragement, and disinclination for mental and physical labor. It is rarely, though sometimes, accompanied by nausea. It is rarely accompanied by general increase in temperature of the head, though a local rise is usual.

The treatment of these affections involves keeping the patient as quiet as possible and away from bright lights and exciting circumstances of all kinds. All exercise, whether physical or mental, except the most moderate, should be avoided. The diet should be simple and unstimulating. If any acidity should appear in the stomach it should immediately be neutralized. The bowels should be kept entirely free. If there is irritation of the bladder, measures should be taken to allay it. All sexual indulgence or excitement should be avoided. All the sleep that can be secured should be had. The patient should sleep upon a gently-inclined plane formed by putting blocks of wood from four to eight inches in height under the head-posts of the bed. By this means the blood is made to gravitate away from the head, and relief is obtained. If possible, a warm climate and a locality high above the sea-level, where the barometric pressure is low, should be secured. The surface should be thoroughly protected from exposure to cold air. Alcoholic stimulants and strong coffee and tea, as a rule, should be avoided in this form of headache. Protracted hot foot-baths are in order.

Among medicines, opium is the most generally useful, either in the watery pilular extract or in the deodorized tincture. It should be given in doses of such size and frequency as to subdue the pain, and should be continued in conjunction with other measures until the pain subsides, when the use of the anodyne may be gradually withdrawn. Side by side with this it is necessary to employ large doses of the iodide of potassium. For an adult, ten grains may be given three times a day to begin with. Each day the dose may be augmented by five grains, until decided evidences are given that the remedy has produced results. If duly diluted with water, from fifty to one hundred grains may be given three times a day if necessary. If the disease is of syphilitic origin, inunctions of mercury may be employed. For this purpose the oleate is to be preferred in the strength of ten grains of the stronger oleate to an ounce of cosmoline perfumed with a little oil of roses. Inunction should be practised twice daily until the effect of the mercury is produced. Counter-irritation behind the ears and along the back of the neck by means of the actual cautery or by blistering collodion Dr. Jewell has found useful. Under this treatment, in the course of a few days, or, at most, of a few weeks, the pain abates. Tonics, as acid solutions of strychnia and quinine, may be given at this stage as required.

THE INDUCTION OF ABORTION AS A THERAPEUTIC MEASURE.—Dr. Priestley recently read a paper under this title before the London Obstetrical Society (*Med. Times and Gaz.*, vol. i., 1881, p. 50), in which the following reasons were adduced as justifying the induction of abortion. 1. Pelvic deformity so great as to preclude the birth of a viable child. 2. Narrowing of the genital canal by tumors, cicatrices, or cancers so as to prevent the passage of a viable child. Great care is here necessary not to overestimate the amount of obstruction. If a series of cases of Cæsarean section with fair success should occur, the reasons for inducing abortion in such instances would be undermined. In cases of cancer there is fair ground for this operation, since the woman has but a short time to live in any case. 3. In obstinate vomiting of pregnancy, where all other expedients are fruitless and a fatal result is anticipated if relief cannot be afforded. 4. In eclampsia abortion should only be induced as a last resort to save life. 5. In irreducible retroversion or retroflexion of the gravid uterus, but only where life is seriously threatened, not merely because the displacement is irreducible. 6. In severe hemorrhage. 7. In certain other diseases, where the complication of pregnancy is undoubtedly endangering life. The responsibility of inducing abortion should never be undertaken without a consultation.

MULTIPLE CUTANEOUS GANGRENE DUE TO CACHEXIA.—In 1878 Professor Simon first called attention to this comparatively rare disease, which for the most part affects children of various ages and has a malignant character. Dr. Eichhoff recently observed a case of this kind at the Breslau clinic for cutaneous and syphilitic diseases. The child, three years old, was first seen in April, and was then suffering from extensive eczema of the face, breast, and back. Constitutional symptoms were not marked at this time, and the eczema rapidly yielded to appropriate treatment. In May the child was again brought to the clinic, when its general health was found to be much depreciated. The back had been covered with dark-red patches, the largest about the size of a millet-seed. Vesicles soon appeared above these patches, but they rapidly collapsed, leaving ulcers, which soon became gangrenous. The sloughing extended deeply down into the subcutaneous connective tissue. Local and constitutional treatment caused these sloughing ulcers to heal with cicatrices resembling those of variola. Some time after this a corneal ulcer developed, and simultaneously with its appearance the head became affected with gangrenous ulcers. The latter slowly healed, leaving deep cicatrices. A second exacerbation occurred in June, and again a corneal ulcer was one of the complications. The ointment, applied locally, consisted of fifteen parts each of camphor and myrrh, with one hundred parts of vaseline.

The pathogenesis of this affection was said to resemble that of ordinary bed-sores. The appearance of the corneal ulcers was explained by the depreciation of the child's general health and insufficient *vis a tergo.—Deutsch. Med. Woch.*, August 21, 1880; *New York Medical Record.*

COMMUNICABILITY OF PUERPERAL FEVER BY THE MEDICAL ATTENDANT.—In a paper on this subject (*Brit. Med. Jour.*, 1880, p. 771) Dr. Macdonald concludes as follows. 1. The diligent and intelligent employment of antiseptic precautions and appliances, good ventilation, and extreme cleanliness are capable of diminishing very largely the occurrence of septicæmia, both in maternity hospitals and in private practice. 2. If antiseptics are carefully and systematically employed, there should be no case of the communication of the disorder from one patient to another by the medical attendant, even when he performs for the sick person all the duties that are incumbent upon him as a medical adviser. It is always, however, to be understood that the doctor restricts himself to his own duties and does not encroach upon those of the nurse, and that his measures to secure perfect antisepsis shall be thorough in all cases where there is the slightest suspicion of septicæmia. It follows also, if these views are correct, that the recommendation, so frequently given to an obstetrician, to leave his practice, in case he meets with puerperal fever, is both unnecessary and unsatisfactory, inasmuch as it tends to the neglect of the most reliable measures of safety,—namely, constant attention to cleanliness and thorough and complete disinfection,—whilst it puts upon the obstetrician a burden that is too heavy for him to bear, and which, indeed, is not borne by the very people who are loudest in recommending its necessity.

THE TEMPERATURE IN TUBERCULAR MENINGITIS.—Dr. Jules Turin (*Med. Times and Gaz.*, vol. i., 1881, p. 75; from *Jahrb. f. Kinderkr.*) sums up the question of temperature as follows. 1. Tubercular meningitis is always accompanied by a rise in temperature in one or other of its stages, but seldom during its entire duration. 2. In a few cases only does the disease begin with a sudden rise of the bodily heat, as in some forms of acute disease. 3. The thermometric results are extraordinarily variable, so that it is quite impossible to establish any typical temperature-curve. 4. In uncomplicated cases of tubercular meningitis the temperature rarely exceeds 102.2° F.; it generally varies between 100° F. and 102° F., but it may also sink some degrees below the normal. 5. The most common type is the remittent, with the usual day fluctuations. The variations within twenty-four hours are normal, or more than normal; sometimes they are very irregular, with more or less sudden rise or fall at any stage and at different periods in the twenty-four hours. 6. If the tubercular meningitis is the terminal of some previously-existing febrile disease,—as, for instance, a coxitis, or any bone or other joint lesion,—the average temperature will be higher than in other cases, but in other respects the course of the disease will be unaffected. 7. In the cases with acute general miliary tuberculosis the febrile exacerbations are more considerable and the variations more marked.

TREATMENT OF OZÆNA.—In several severe cases of chronic inflammation of the nasal and pharyngeal cavities giving rise to offensive discharge, Dr. Poore (*Lancet*, vol. i., 1881, p. 13) has found decided benefit result from the use of a stimulant and antiseptic snuff having the following formula: biborate of soda, nitrate of bismuth, of each one drachm; disulphate of quinine, ten grains; iodoform, five grains. This snuff has the effect of stopping the fetor and greatly diminishing the amount of discharge from the nostrils. It is liable, as are all snuffs when used for similar conditions, to cake in the nostrils, and it is therefore necessary to wash out the nostrils thoroughly once a day. This may be done with the nasal douche, or patients may be taught to snuff a lotion up the nose and allow it to run out of the mouth. A teaspoonful of glycerin of borax dissolved in a wineglassful of tepid water forms an excellent wash for the nose. When there is no bone trouble, sulphide of calcium in doses of half a grain (in pill) thrice daily often benefits the condition. It is often necessary to cleanse the nasal and pharyngeal cavities with a brush inserted through the anterior nares, and also behind the soft palate, so as to reach the summit of the pharynx. The brush may be moistened with glycerate of tannin, and, after the cavities have been cleansed, a little dry iodoform may be passed into the cavities on the tip of the brush.

UNUSUAL FORM OF TELANGIECTASIS.—Mr. Gay reports (*Lancet*, vol. i., 1881, p. 135) a case of telangiectasis occurring in a girl eight years old, which occupied the whole of the right cheek. It seemed to be a teratological development of the venous at the expense of the muscular elements, especially that of the buccinator muscle; for the muscular tissue had receded and disappeared before the growth of the tumor: so that the tumor bulged outward on the cheek very considerably, showing its blue color in patches through the skin, which was extremely thin. On the inner side of the cheek it also bulged as a closely-packed mass of large convoluted veins, which at length protruded so far as to incommode the child in talking and masticating, by getting between the teeth. From the cheek the growth extended in a broad and irregular band across the back of the mouth and the hard palate, the mucous membrane of the entire half of which was occupied by large veins exalting themselves considerably above the normal

level. Mr. Gay operated under ether with the red-hot needle, and gradually succeeded in eradicating the growth, piecemeal, almost entirely. The operations were accompanied by much hemorrhage.

Syphilitic Affections of the Lung.—Gamberini, of Bologna (*Brit. Med. Jour.*, 1881, p. 21), says that laryngeal lesions often precede or accompany syphilitic pulmonary affections. The symptoms of syphilis of the lung are generally those of pneumonic phthisis, from which during life there may be no certain means of distinguishing it; even after death the distinction cannot always be made between gumma and tubercle, especially when the gummy nodules are in a state of caseation or are infiltrated. It must be noted that syphiloma most usually spares the apex, whereas tubercle most frequently attacks that portion of the lung. This, however, is not constant, as has been shown by Fournier. The course of pulmonary syphilis is generally slow and apyretic, which is not usually the case in tubercular phthisis. Syphilis also is accustomed to attack only one lung, and one part of the lung. This tendency to localization is considered by the author to be a very important point in the diagnosis of pulmonary syphilis, whether the lung be attacked at an early or at a late stage of the disease.

MISCELLANY.

International Medical Congress, London, 1881.—Preparations for the approaching International Medical Congress are being vigorously pushed forward by the Executive Committee, and the arrangements are now beginning to take definite form.

The inaugural address, by Sir James Paget, the president-elect of the Congress, will be given in St. James's Great Hall, which has been already engaged for the purpose, on Wednesday morning, August 3. The following mornings will be devoted to the business of the various Sections, while the afternoons (with the exception of Saturday afternoon, which will be left free for garden-parties, excursions, etc.) will be occupied by the general meetings of the Congress, at which four addresses will be given by distinguished men of four nationalities. Three gentlemen have already promised to give these addresses:—Prof. Huxley, probably on "The Connection of General Science and Medicine;" Prof. Volkmann, of Halle, on "Modern Surgery;" and Dr. Billings, of Washington, on "Medical Literature:" the fourth address, to be given by a distinguished Frenchman, has not as yet been finally arranged. The meetings of the various Sections will be held in rooms at Burlington House, courteously placed at the disposal of the Committee by the University of London, the various learned societies, and the Royal Academy of Arts. This, however, not providing the required amount of accommodation, the Committee have engaged Willis's Rooms for the occasion, and four of the Sections will hold their meetings there. As stated in an earlier notice, no less than forty thousand individual medical men in various parts of the world received the original circular of invitation during August and September of last year, and since then the secretaries of the various Sections have been actively engaged in circulating provisional lists of subjects which seemed in the opinion of the committees of the Sections those best suited for discussions and papers. Numerous replies have been received in answer to the communications, in some cases leading to alterations in the subjects selected. These amended programmes have again been distributed among those most likely to take interest in them, and are now combined into a pamphlet, and are issued, together with the rules of the Congress, printed in the three official languages, to any medical man making application for them to the secretary-general. Since the list of names published in November last, a large number of our foreign colleagues have definitely announced that they will come to the meeting, and there seems every prospect of the attendance from abroad being a full one: meanwhile, depending on the number of names appearing as officially connected with the Congress, and in the subscription-list, together with the number of gentlemen from abroad who have positively stated their intention to attend, a certain estimate of one thousand members may be made, and it seems not unreasonable to assume that at least double that number will attend.

The Reception Committee are busily engaged, and have decided upon giving an evening reception at South Kensington, and perhaps a second in the Albert Hall. The Lord Mayor purposes entertaining members of the Congress at dinner at the Mansion-House on August 4.

Commencements of the Medical Colleges of Philadelphia.—The Fifty-Fifth Commencement of the Jefferson College was held on March 12, 205 men graduating. The names of the prize-men were Henry Dickson Bruns, John Ellegood, S. Howard Wilson, J. Charles Martin, Edward Winslow Taylor, L. L. Artis, A. J. Dodds, George W. Stout, and L. L. Rogers. Professor Bartholow delivered the valedictory.

The One-Hundred-and-Fifteenth Commencement of the University of Pennsylvania was held on March 15, 115 men taking the degree of Doctor of Medicine and 47 that of Doctor of Dental Surgery. The prize- and honor-men were George E. De Schweinitz, J. P. Crozer-Griffith, Orlando C. Robinson, Louis J. Lautenbach, Thomas D. Dunn, Guy Hinsdale, Eugene H. Dickenshied, Joseph B. Scott, John B. Gibbs, John J. Buchanan, Moyses Marcondes, and Louis D. Brose, the

honor-men including only those who received a higher average than 95. The valedictory was pronounced by Professor H. C. Wood.

The Commencement of the Woman's Medical College was held on March 17, 19 women graduating. Professor Rachel Bodley delivered the valedictory, in the course of which she stated that 276 women had graduated from the school, of whom 150 are at present in practice. The average annual income of the graduates is $2907; 12 make over $5000 and 4 over $15,000. This statement ought to bring recruits to the college benches.

GENEROUS DONATIONS TO MEDICAL OBJECTS.—It is stated that Honorable Thomas A. Scott has presented $50,000 each to the University and Jefferson Medical College and $30,000 to the Orthopædic Hospital. The trustees of the University design using their donation for the purpose of endowing the chair of Mathematics; but the authorities of the Jefferson College, we suppose, intend to endow one of the medical professorships.

THE thirty-second annual session of the American Medical Association will be held in Richmond, Virginia, on Tuesday, Wednesday, Thursday, and Friday, May 3, 4, 5, 6, 1881, commencing on Tuesday at 11 A.M.

STATISTICS OF CANCER OF THE BREAST.—Vienna statistics show 366 out of 30,000, or one per cent., of female bodies examined post mortem, to present cancer of the breast. In 184 cases that had been operated upon, there were 105 in which metastases had occurred. These were absent in only 41 out of 182 that had not been operated upon. Metastatic secondary cancer occurred most frequently in the lymphatic glands (192), in the respiratory organs (132), and in the digestive organs (139), of which 127 occurred in the liver.—*Med. Times and Gaz.*, vol. i., 1881, p. 48; from *Centralbl. f. Chir.*

READY METHOD FOR HOT FOMENTATIONS.—Place the flannels in the steamer of an ordinary potato steam-kettle. They readily become permeated with the steam when the kettle is placed on the fire, and can be readily changed without any fear of scalded fingers during the attempt to wring them sufficiently dry, as in the ordinary method.—*British Medical Journal.*

MR. STEPHEN JENNER, grand-nephew of the discoverer of vaccination, and himself in childhood the subject of many of his uncle's experiments, is living at the age of eighty-eight, in great poverty, at Heathfield, near Berkeley, England.

A FRENCH TRANSLATION OF DUHRING ON THE SKIN.—We learn that Professor Fournier, of the St. Louis Hospital, has requested permission, on behalf of a former pupil, to translate Professor Duhring's treatise on skin diseases, with notes, for the French practitioner.

THE Professorship of Dermatology in the University of Vienna, made vacant by the death of Hebra, is being contested for by Professors Kaposi, Auspitz, and Neumann, of whom the first is the son-in-law of the late professor and was associated with him in the production of his great work on diseases of the skin. It was at first announced that Kaposi would be chosen without a contest.

CHILBLAINS.—Mr. W. Squire (*Brit. Med. Jour.*, vol. i., 1881, p. 181) says he has found all the vaunted external remedies for chilblains fail in his hands, and he recommends opium, with a little Epsom salt and syrup of ginger, night and morning. The relief is usually rapid.

THE Surgical Society of Paris has awarded the Duval prize to M. Paul Segond, Prosector in the Faculty, for his work on "Acute Abscesses of the Prostate," and has equally divided the Laborie prize between M. L. H. Petit, for his essay on "Palliative Operations in Cancerous Subjects," and M. A. Heatherbe, for his work on "Calcified Epithelioma."

THE West Virginia Legislature has passed a bill creating a State Board of Health.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM MARCH 6 TO MARCH 19, 1881.

WHITE, C. B., MAJOR AND SURGEON.—Granted leave of absence for three months on Surgeon's certificate of disability. S. O. 57, A. G. O., March 11, 1881.

BROWN, H. E., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Fort Duncan, Texas, to accompany battalion First Infantry to Fort Davis, Texas, and, on arrival there, report to the Commanding Officer for duty as Post-Surgeon. S. O. 35, Department of Texas, February 26, 1881.

GIRARD, J. B., CAPTAIN AND ASSISTANT-SURGEON.—Having reported in person, is assigned to duty at Fort Verde, A.T. S. O. 23, Department of Arizona, February 26, 1881.

TAYLOR, B. D., CAPTAIN AND ASSISTANT-SURGEON (now in San Antonio).—To report to the Commanding Officer, Fort Ringgold, Texas, for duty as Post-Surgeon. S. O. 40, Department of Texas, March 7, 1881.

GARDINER, J. DE B. W., CAPTAIN AND ASSISTANT-SURGEON.—The leave of absence granted him in S. O. 16, February 8, 1881, Department of Arizona, is extended five months, and so much of S. O. 34, c. s., A. G. O., as relates to him is revoked. At the expiration of his present leave of absence, to report by letter to the Surgeon-General. S. O. 59, A. G. O., March 14, 1881.

GIBSON, R. J., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Granted leave of absence for one month, and permission to apply for fourteen days' extension. S. O. 47, Department of the Missouri, March 10, 1881.

ARTHUR, WILLIAM H., FIRST-LIEUTENANT AND ASSISTANT-SURGEON (recently appointed).—To report in person to the Commanding General, Department of the Platte, for assignment to duty. S. O. 62, A. G. O., March 17, 1881.

BUSHNELL, GEORGE E., FIRST-LIEUTENANT AND ASSISTANT-SURGEON (recently appointed).—To report in person to the Commanding General, Department of Dakota, for assignment to duty. S. O. 62, c. s., A. G. O.

BIRMINGHAM, H. P., FIRST-LIEUTENANT AND ASSISTANT-SURGEON (recently appointed).—To report in person to the Commanding General, Department of the Missouri, for assignment to duty. S. O. 62, c. s., A. G. O.

WYETH, M. C., FIRST-LIEUTENANT AND ASSISTANT-SURGEON (recently appointed).—To report in person to the Commanding General, Department of Dakota, for assignment to duty. S. O. 62, c. s., A. G. O.

PHILADELPHIA, APRIL 9, 1881.

ORIGINAL COMMUNICATIONS.

REMARKS UPON CLINICAL PHASES OF POISONING BY ALCOHOL.

Read before the Philadelphia County Medical Society, January 12, 1881,

BY FRANK WOODBURY, M.D.,
Physician to the German Hospital, Philadelphia, etc.

"CHINESE historians affirm that wine in which the feathers of the Tchin are macerated becomes a deadly poison."* Modern science confirms this clinical observation, but ascribes the fact to a more constant and less fabulous cause. Alcoholic liquors are poisonous because they contain alcohol. Since the various intoxicating beverages in use consist essentially of dilute ethylic alcohol, their toxic effects may be considered in common under the comprehensive title of alcohol-poisoning.

From the universality of the use of these beverages by all races† of men and in all ages, it would at first sight appear that alcohol might be a valuable food. So it was considered by Liebig; whose views were, however, entirely controverted by Perrin, Lallemand, and Duroy, who showed that it was excreted by the lungs, the kidneys, and the skin without undergoing oxidation in the body. Later observers, notably Subbotin, have shown that the ingestion of alcohol does not increase the excretion of carbonic acid, but, on the contrary, reduces it; does not raise the daily amount of urea, but lowers it; does not increase the temperature of the body, but positively reduces it; and does not increase hæmatosis, but, on the contrary, interferes materially with the blood-making function. Such effects are certainly not those of a food, but of an agent which directly impairs nutrition. Anstie and Dupré declared that a certain amount of alcohol disappeared in the passage through the system, and believed that this comparatively small amount was assimilated as food. Parkes and Wollowicz subsequently determined the maximum amount that could be thus assimilated by a healthy man to be from one and a half to two ounces of absolute alcohol per diem.† The latter observers found that when an amount of liquor corresponding with only one ounce of absolute alcohol was administered, no alcohol could be detected in the urine. Upon repeating these experiments, however, I found, in an adult of temperate habits, that so small a quantity as one-fourth of the above gave decided evidence of its presence in the urine; and I believe Anstie also detected alcohol in the urine after a single glassful of sherry. Possibly, this may be explained by idiosyncrasy, but it seems more probable that the person experimented upon by Parkes and Wollowicz had by habit acquired the power of consuming a greater quantity than could be assimilated by an organism unaccustomed to its use.

I am, therefore, forced to the conclusion that alcohol is not a true food in the sense that it favors nutrition in a state of health. Of its value as an accessory food under certain emergencies I shall not speak at present, as it is not germane to our subject; nor shall I enter upon a consideration of the dietetic use or abuse of alcohol. I have broached the subject of its use in health merely in order to establish, if possible, the commencement of its toxic effect. From personal experiment I have concluded that the standard adopted by recent experimenters of one ounce and a half to two ounces of absolute alcohol is rather above the average amount which can be assimilated by the healthy organism, unless given in frequent and very small doses. Alcohol is eliminated slowly from the system, except when excessive amounts have been taken; it then rapidly appears in the urine, in which traces of it usually continue for from sixteen to twenty-four hours. In one case, within ten minutes after drinking about four ounces of whisky, a quantity of limpid urine was passed, whose specific gravity was only 1001½; it evidently contained considerable alcohol.

Of the fact that alcohol, in certain

* I. Klaproth, Lettre à M. Humboldt sur l'Invention de la Boussole, p. 89. Quoted by Thompson in "The Philosophy of Magic," vol. i. p. 41, London, 1846.

† The Mohammedans and Hindoos have been cited as exceptions to this rule because such use is forbidden by their religion; but no one will claim that therefore drunkenness is entirely unknown among them.

‡ The equivalent of alcoholic beverages for a healthy adult, as stated by Parkes, is as follows: two fluidounces of brandy, or five ounces of the strong wines (sherries, etc.), or double the quantity of the weak wines (clarets and hocks), or twenty ounces of beer. "If these quantities be increased one-half, one and a half ounces of absolute alcohol will be taken, and the limit of moderation for strong men is reached." Parkes's Principles of Hygiene, 5th ed., Philadelphia, 1878, p. 298.

amounts, is capable of causing death, there can be no question whatever: on this point all writers upon toxicology are agreed, and numerous cases might be cited in proof. Tardieu, for instance, records a medico-legal case where a man was induced by a wager to drink within a short time a bottle of brandy. He accomplished the task, fell to the floor in a state of coma, and died in sixteen hours.*

In its concentrated forms, when taken into the stomach, alcohol may cause death from local action upon the mucous membrane, producing softening and abrasion and violent gastro-enteritis. Two tablespoonfuls of sixty per cent. strength have proved sufficient to cause the death of a child.† As in other remedies, different effects may be expected when exhibited in the single toxic dose, in the interrupted dose, and in the continued dose. For convenience of discussion, although not exactly synonymous, let us consider the clinical accidents arising from the first two under the head of acute alcoholic poisoning, and those of the latter under chronic alcoholism. In so doing we shall follow the dictum of Magnus Huss, who first called the attention of the profession to the symptoms of chronic alcoholic poisoning under the title of alcoholism.‡

Let us first consider the effects of acute alcohol-poisoning, where coma, with complete muscular resolution, exists. Since this condition often terminates fatally, it is important to distinguish it from insensibility from other and widely different causes, such as cerebral apoplexy, hysteria, uræmic coma, opium-poisoning, concussion of the brain, and similar conditions. Dr. H. C. Wood says that "when the patient is simply seen in the advanced stage of deep coma an absolute diagnosis cannot be made out."§ I think, however, that by attention to the objective conditions we may make a tolerably certain diagnosis by exclusion. Without taking up each of these different diseases with which alcoholism may be confounded, let me say, in brief, that, while in this condition coma and complete muscular prostration may exist, there is no difference between the two sides of the body as regards muscular tonus or surface-temperature; the latter is below rather than above the normal. More especially is it to be noted that there is no hemiplegia. The pupils are not constant; generally they are moderately contracted; before death they may dilate. There is no conjugate deviation of the eyes, as often occurs in apoplexy and injuries of the brain. Hemorrhage into the pons Varolii, however, is said to be accompanied by contracted pupils, coma, and general muscular resolution. The pupils in cerebral hemorrhage are usually irregularly dilated. MacEwen, of Glasgow, recommends the alteration which occurs in the pupils when the patient is disturbed as a reliable sign of alcohol-poisoning. The pupils in such a case will dilate temporarily if the patient be shaken or his beard pulled. This merely proves that the condition is rather one of deep stupor than of complete coma. I cannot believe that a case of true coma would have a mobile pupil, or, if it should dilate under such circumstances, that it could afterwards again contract.

I have not mentioned as distinctive the test commonly relied upon, *i.e.*, that furnished by the alcoholic odor of the breath. Where it exists it furnishes confirmative rather than conclusive evidence, since the individual may have taken a stimulant just before the attack of illness, or it may have been administered afterwards. It thus becomes a nice question to decide in some cases whether it is alcohol or disease, or both. A much more reliable test is furnished by the urine. In all cases of narcotic poisoning the bladder, as a matter of routine treatment, should be evacuated by a catheter. The urine may be tested for alcohol by adding to it a small quantity of chromic acid test (potassium bichromate one part, acid sulphuric three hundred parts), as proposed by Anstie. But I would recommend the adoption of a slight modification, which has yielded very satisfactory results in the few cases in which I have tried it, as follows. In a medium-sized test-tube about a drachm of clear, colorless sulphuric acid is placed, and about three times the quantity of the urine to be tested is then to be poured down the side of the test-tube, so as to prevent immediate mixing of the fluids; a small crystal (split-pea-sized) of potassium bichromate is then dropped into the tube, which is then given a gentle rotary motion, so as to dissolve a little of the bichromate and diffuse it through the sulphuric acid.

* Clinique sur l'Empoisonnement, p. 848. Paris, 1867.
† Deutsch's case, Schmidt's Jahrbücher, Bd. xxv.; from Preuss. Vereinzeitung.
‡ Die Chronische Alcoholkrankheit, Stockholm, 1852.
§ Therapeutics and Materia Medica, 3d ed., p. 125.

The tube is then set aside in the rack. The limpid lower stratum of liquid will in the course of from a few minutes to an hour assume a decided emerald-green coloration, the depth of the color being proportionate to the amount of alcohol. This test may be confirmed by fractional distillation, provided that enough alcoholized urine can be secured to render it practicable.

In attempting to differentiate these cases from those of apoplexy, it should not be forgotten, however, that alcohol stands in a direct causative relationship to cerebral hemorrhage, as autopsies have proved. In seven cases of death during acute alcoholism, Tardieu* found two with hemorrhages into the lungs, meningeal apoplexy in six, and in four there were also ventricular effusions of blood. This authority concludes that "in death coming on rapidly during the state of drunkenness, pulmonary apoplexy, and especially meningeal apoplexy, are lesions which, if not constant, are at least extremely frequent and almost characteristic." Hughlings Jackson reported a case in which alcohol impregnated not only the breath but the urine, and at the post-mortem examination a large clot was found covering nearly the whole of one hemisphere. The question of treatment of these cases I reserve for discussion farther on.

In other cases of acute poisoning by alcohol, convulsive symptoms supervene, and occasionally epileptiform seizures are very marked, probably owing to the action upon the medulla oblongata of blood deficient in oxygen. I have seen but one case of this kind, which occurred in a mulatto some years ago. After taking from the arm about ten ounces of extremely dark blood, the convulsions ceased and did not return. The next day the man was apparently as well as usual and ready for another spree. In this connection I may also be permitted to mention a case of catalepsy in a slender young man, about nineteen years of age, who came under my care some eight years ago, while resident physician in the Pennsylvania Hospital. He was brought to the institution perfectly unconscious and perfectly rigid. I remember there was some difficulty in getting him out of the carriage, as his body was fully extended, and he was carried in supported by his heels and his head. I found that on forcibly placing his limbs in any position they would remain thus extended in the air as if they were frozen. Upon lifting the closed eyelids the eyes were seen to be rolled upwards and constantly in motion (nystagmus); the pupils were dilated moderately. It was said that this condition came on after drinking a single glass—his first glass—of whisky, and that he was not subject to such attacks. The application of faradic electricity quickly restored the patient to consciousness, and he would gladly have gone home at once if he had been permitted; but he was kept in bed until morning, and then discharged perfectly well, no further treatment being required.

I now come to speak of a form of acute poisoning from the abuse of alcohol, with which all are familiar, the so-called mania a potu, or delirium ebriosum. I will not, therefore, weary you with any reference to cases. Let me say, however, in a word, that the distinguishing trait of this condition is that it occurs as a result of an overindulgence in alcohol in an organism unaccustomed to its use: it is the form that appears in men who go on occasional sprees, with periods of temperance or total abstinence between. Such cases have active delirium, characterized by delusions and homicidal tendencies. The condition is characterized by great nervous and vascular excitement, the face is flushed, the eyes bright, the ego elevated. The diagnosis and prognosis are based solely upon the history of alcoholism, for to all intents and purposes the patient is suffering from acute mania. When this condition is compared with chronic alcoholic poisoning and, in its characteristic form, delirium tremens, a marked contrast is seen to exist. This condition, as originally described by Sutton, is essentially one of nervous and vascular depression. The face is pale, the eye dull, there are illusions in place of delusions, a suicidal tendency takes the place of a homicidal, and melancholy replaces mania. Sleeplessness exists in both, but in one it is due to cerebral congestion, in the other to cerebral exhaustion. Tremor of the muscles is a marked symptom of the latter, and gives it its name.

I shall not here attempt a detailed consideration of the various diseased states that are associated with chronic alcohol-

* Observations médico-légales sur l'Etat d'Ivresse considéré comme Complication des Blessures et comme Cause de Mort prompte ou subite. Ann. d'Hyg. Publique et de Méd. Légale, tome xl., 1848, et Dict. de Méd. Prat., *loc. cit.*

ism, since many of them are only indirectly due to it. In the words of Boehm,* "The poison of alcohol, either alone or combined with other pathological causes, produces bodily or mental diseases which in themselves afford nothing characteristic of the effects of alcohol." That it is a most fruitful source of disease, both physical and mental, all authorities are agreed, the tendency of alcohol being to cause fatty degeneration and sclerotic changes in all the soft tissues of the body. Nor shall I essay the enumeration of the various diseases attributed to alcohol; in the words of Bartholow, they may be summed up as "sclerosis and steatosis."

The point, however, that I would now insist upon, and which I consider has a most direct bearing upon the treatment of alcoholism, is this: the long-continued existence of alcohol in the blood produces important changes in nutrition, to which the system in a measure accommodates itself, so that the patient requires less food to support life than without the alcohol (as in a case quoted by Anstie,† where a tailor drank a bottle of gin daily for years, and who took in addition a small piece of bread each day as his only sustenance). In such cases it cannot be doubted that alcohol plays the rôle of an accessory food, and changes take place, converting the organism into an alcohol-burning apparatus, and correspondingly unfitting it for the ordinary carbo-hydrates and hydro-carbonaceous food. This will, I think, serve in a measure to explain why depriving a drunkard of his drink may cause a sudden failure of nutrition with the rapid appearance of an outbreak of delirium, denotive of cerebral exhaustion, and characterized by failure of mental power, hallucinations, prostration, and muscular tremor. Let me repeat the fact that in health, if at all, only very small amounts of alcohol are consumed by the system, but in chronic alcoholism the tissues have undergone such changes as to confer upon them the power to derive force from alcohol, which unfits them to a corresponding extent for normal nutrition.

The term delirium tremens was adopted by Sutton in a work published in 1811, in which he took especial pains to show that the symptoms were not due to phrenitis or meningitis. He showed also that bleeding and blistering were generally fatal, and that these cases need a supporting treatment, and especially opium.

Strangely enough, in "Ziemssen's Cyclopædia" (*loc. cit.*), Prof. Boehm, in referring to Sutton's work,‡ gives this author due credit for originality in the use of the term delirium tremens; but, on the other hand, he states that it was reserved for Rayer in 1819 to indicate alcohol as the prime factor in the etiology of the disease. It is quite evident that he had not read Sutton's tract on Delirium Tremens, or he could not have said that this author had overlooked its connection with alcoholic excess. Here is what Sutton, after reporting several cases, says:§ "It has been remarked in several of the above instances that the parties attacked by delirium tremens have been given to drinking; and I feel firmly persuaded that all cases of this disease are connected with indulgences of that nature." Could language be more plain and unequivocal than this? Again, he says,‖ "But that fermented liquors, and more especially spirits, are the general cause of the disease, is rendered certain by the frequency of it in situations where the indulgence of them can be had at a reasonable rate. On the coast of East Kent, where I was first led to distinguish this affection, and at the time alluded to, spirits brought in by smugglers might be had in great abundance at a cheap rate; and such as labored under delirium tremens in that quarter were mostly those who confessedly indulged in the use of spirits to excess."

Several varieties of delirium tremens have subsequently been indicated by industrious investigators which we cannot now consider, such as febrile delirium tremens, which, according to Magnan, generally runs a fatal course in a few days, and is probably connected with some local inflammation, such as meningitis. Nor need I discuss the uræmic form of Surmay.¶ Epileptic insanity may at any time occur as a complication. Dipsomania is undoubtedly a psychosis, often inherited, sometimes due to traumatism or severe mental shock, not necessarily dependent upon previous alcoholic excess. The clinical forms of confirmed alcoholism

known to the alienist—such as pachymeningitis hæmorrhagica, general paralysis, melancholia, and hopeless insanity (hopeless because dependent upon sclerotic and fatty changes with atrophy of the brain)—are conditions belonging directly to our subject, but which need not at present engage our attention.

Let us, however, in conclusion, consider very briefly the therapy of the three forms most commonly encountered by the general practitioner,—*i.e.*, alcoholic coma, mania a potu, and delirium tremens,—a subject which has given rise to a good deal of controversy. In the first place I will consider coma. In rapidly-fatal cases of alcoholic poisoning, failure of respiration commonly occurs previous to cessation of the heart's action. Therefore, besides the ordinary treatment of narcotic poisoning by the use of the stomach-pump and purgative enemata, and the application of warmth to the extremities, it will be proper to fortify the action of the respiratory centres by the hypodermic administration of (gr. $\frac{1}{120}$) atropia with (gr. $\frac{1}{12}$) morphia, repeated at proper intervals. The urine should be drawn off, both for examination and to encourage the action of the kidneys. It may also be necessary to employ electricity and artificial respiration to assist the lungs in excretion of the surplus of carbonic acid, which now tends to accumulate in the blood. Indeed, Sampson, an English physician, in the treatment of such a case found himself obliged, as a last extremity, to resort to tracheotomy, which proved successful.*

Reginald Southey,† in a recent lecture on this subject, deprecates active measures, because if the case should happen to be one of hemorrhage into the pons Varolii, instead of one of alcohol-poisoning, such treatment would be improper; but since the cases of hemorrhage into the pons must be quite rare compared with those of alcohol-poisoning, and since they are invariably fatal under any method of treatment, I regard them as entirely out of the question, and should treat such a case as one of alcoholic coma. As soon as the patient has his stomach emptied by the stomach-pump, a pint of hot coffee may be thrown into its cavity and allowed to remain. Inhalations of ammonia will greatly assist in reviving the patient. An individual supposed to be insensible from alcohol should never be allowed to remain in a state of coma to sleep off a fit of drunkenness. Too often it proves his last sleep, either from carbonic acid poisoning or from secondary cerebral hemorrhage.

Acute mania induced by alcohol is commonly subdued by ether- or chloroform-inhalations and hypodermic injections of morphia. In such cases I have known a grain of morphia to be administered with only good results. The standard prescription for the minor forms of acute alcoholism is one containing bromide of potassium and chloral in decided doses, given every two hours until sleep is obtained. Where there is much arterial tension, the tincture of hyoscyamus or hyoscyamia has been highly recommended. Care should also be taken to give nourishment frequently, in a form easy of assimilation on account of the possible gastric inflammation. The patient will be found more manageable when confined to his bed, and it often becomes necessary to strap him down. During convalescence stomachic tonics to improve the digestion may be given. For this purpose occasional laxatives and tincture of capsicum, tincture of nux vomica, and compound tincture of cinchona may be used with advantage. To diminish the appetite for strong drink, a freshly-prepared fluid extract of cimicifuga with tincture of capsicum may be steadily employed, as recommended by Bartholow.

I will not dwell upon the treatment of delirium tremens further than to say that it requires pre-eminently a symptomatic and supporting treatment. Such cases generally suffer from numerous other evils, among which we notice prominently chronic gastric catarrh, owing to local action of the alcohol upon the mucous coat of the stomach causing atrophy of the peptic glands and increase of submucous connective tissue. Foods, therefore, which are digested in the small intestine, and peptones, are particularly required.

If I have correctly stated the conditions existing in acute and chronic alcoholism, I think it will be seen that good reasons exist why the administration of alcohol as a part of the routine treatment is as necessary in true delirium tremens and in chronic

* Article Alcoölisme, Nouveau Dict. de Méd. et de Chir. Pratiques, Paris, 1864.

† London Lancet, December 18, 1880.

alcoholism as it would be improper in acute alcoholic poisoning. I am fully aware that the routine administration of stimulants is not uncommon in these cases,—which is partly due, I think, to the fact that these states are often confounded clinically under the common title of alcoholism, although their different pathology is insisted upon by almost all the text-books. Then, if we separate clinically the effects of acute alcoholic excess from the condition of chronic alcohol-poisoning, with or without delirium, I believe that we are in a position to institute a rational treatment for mania a potu and delirium tremens.

To summarize:

1. Acute alcoholic poisoning, manifesting itself in the forms of coma, convulsions, and mania a potu, is characteristic of the physiological action of alcohol upon a system unaccustomed to its use. Its treatment, in cases of coma and convulsions, is like that of the other narcotic poisons producing paralysis of the respiration, but in mania powerful cerebral sedatives are required. During the after-treatment alcohol is not necessary, but, on the contrary, every encouragement, both by precept and by prescription, should be given the patient to adopt total abstinence as his only chance of safety.

2. Chronic alcoholic poisoning, exhibiting itself in the form of the horrors, vigilance, delirium tremens, or melancholia, on the contrary, bespeaks the existence of a depressed condition of the vital powers due to saturation of the system with alcohol, and consequent degenerative changes. Such unfortunate cases, suffering from what might be called an alcoholic diathesis, require careful nursing, a supporting treatment, and the continuance of stimulants, which to them have become both food and drink.

218 South Sixteenth Street, Philadelphia.

Therapeutic Value of Tartar Emetic.—Dr. A. B. Arnold, of Baltimore, thinks this remedy has fallen into undeserved neglect. In inflammatory croup it is capable, if early used, of keeping it in the catarrhal stage and preventing its passage into the membranous form. He gives in these cases one-twelfth of a grain every hour to a child. In one case, aged six years, he gave one-fourth of a grain every hour, with excellent results.

THE PHYSIOLOGY OF CLIMATE, SEASON, AND ORDINARY WEATHER-CHANGES.

BY ALEXANDER RATTRAY, M.D.,

San Francisco.

(Concluded from page 395.)

THE true *cause* and *sequence* of the above-discussed physiological phenomena will now be apparent. One of the earliest and most important effects, if not the primary effect, of climate, season, and weather-changes, is on the blood. Through the re-distribution of this the many different tissues, organs, and functions are secondarily influenced. Of this these effects are merely the outward manifestation, the most important being in the organs of vegetable life, those of animal life being less important and of subsequent manifestation.

The *primary* object of the climatic law to which the entire circulation is so obedient is to adapt the body to altered meteorological conditions, and chiefly, first, to keep its temperature at a normal physiological or healthy standard (slightly different in different persons), reducing it in warm temperatures by spreading the blood out in shallow streams and thus cooling it partly by radiation and partly by evaporation, and in cold air to preserve the caloric by concentrating the blood in the interior and increasing the lung-function and blood-oxidation; second, to carry on the necessary blood-purification chiefly by the lungs, skin, kidneys, and liver,—that is, those organs which excrete useless or hurtful matters.

The *ulterior* object of this climatic law of the circulation is salutary and *hygienic*,—that is, meant to keep the body in health. The resulting physiological changes, both hæmatic and functional, are vicarious and compensatory. Proof has been given that frequent change of climate, season, and weather tends to increase both the ordinary and the vicarious action of the involved organs. These changes tend to assimilate the various tissues, organs, and functions of the natives of one zone to those of native races, to meet the requirements of the foreign clime for which they are not and perhaps never can be altogether physiologically fitted, not even the inhabitants of the temperate zone, who are gifted not only with the strongest constitution, but with the greatest vital resiliency and adaptability to thermometric changes.

These physiological changes mould the pliant human frame to varying meteorological conditions. In short, they tend to *acclimatize* the body and to induce what have been termed the spring, summer, autumn, winter, and also the tropic, temperate, and arctic or antarctic, *constitutions*. On the nice adjustment of this new balance of the circulation and functions we continually depend for health and comfort. Harmonious action is health. Its disturbance is disease. To maintain normal action the blood-flow into the different organs must not amount to more than the above percentage. If greater, the balance is broken, engorgement ensues, and disease results. This hyperæmia and overtaxed function—one or both—begin some of the most frequent and serious diseases that afflict the human race. Hence the importance of the study of the physiological laws of climate, and the value of a complete knowledge of their nature, extent, and mutual relations, especially for hygienic and therapeutic purposes.

Explained thus, the difference in the functional effects of this law arising from age, size, sex, and so on, will be readily understood. As with the spirometric capacity, these are most evident in those of largest frame, *e.g.*, in adults and males; in short, in those who have most blood and thereby show the greatest displacement.

The law also explains the slightly-raised temperature of the surface in warm atmospheres, from increased turgescence of the cutaneous capillaries, activity of the calorific and respiratory processes of the skin. And, as modern research is rapidly proving that increased or diminished activity of organs is accompanied by increased or diminished vascularity and temperature, so it may yet be proved that the temperature of internal parts is perhaps somewhat lessened by their vascular depletion.

The law explains why the pulse and general circulation are slower and feebler in high temperatures. The mass of blood, spread out in the congested and physiologically-active cutaneous capillaries, leaves less to stimulate the heart and those arteries by which the pulse is usually counted.

Since pathological are often merely an exaggeration of physiological processes, it is interesting to notice how fully the above-mentioned phenomena are endorsed by and capable of being correlated with scattered facts supplied by previous writers,—thus proving that in medical as in general science no truth, though apparently immaterial and isolated, is without its value. The post-mortem lightness of the lungs in the tropics, recorded by Parkes, is a result of this climatic law. And, seeing that *heat drains internal organs*, research will probably show a similar anæmic state of the liver, pancreas, and other internal organs and parts. So, also, the morbid changes induced by cold so intense as to be pathological and fatal are a necessary sequel to a perversion of the climatic law of the circulation. Congestion of internal organs is then observed in a more decided form. Thus, Quelmalz found the vessels of the brain turgid and the large vessels and arteries filled by polypous concretions (coagula?). And he rightly refers the sopor preceding death to congestion of the cerebral vessels and effusion of serum into the ventricles. Rosen also observed the intercranial vessels engorged. Cappel found the blood and fluids accumulated chiefly in the thoracic and abdominal organs. Kellie, besides these appearances, notices a bloodless state of the scalp, engorgement of the intercephalic sinuses, and remarkable redness of the small intestines from sanguineous turgescence. These facts prove that *cold congests internal organs*.

The physiological law of climate, which has thus been proved in the Caucasian and Ethiopian races, that is, the inhabitants of the temperate and tropical zones, is doubtless *universal*, and extends to the Mongolian and other races, as well as to the natives of the Arctic and Antarctic circles. In short, it embraces the entire human race, whatever their nationality or clime. The law and its physiological manifestations are necessarily all the more trying when the natives of Arctic or Antarctic regions visit the tropics, or those of the tropical regions the frigid circles, owing to the greater thermometric range and resulting physiological phenomena. The physiological phenomena resulting from season and ordinary weather-changes are likewise universal, and affect the natives of every zone.

Modern research is thus continually developing the influential part played by those wide-spread and now easily-controlled agencies once termed the "imponderables" (heat, light, actinism, electricity,

magnetism, gravitation, cohesion, and chemical affinity) in many of the great operations of nature, both in the animate and the inanimate world, and nowhere more than in the human body. Of these, *heat* and its absence *cold*, especially the former, are the most powerful. Indeed, there are few more important subjects for medical study than the influence of temperature on the human frame. Heat is a never-absent element in every process of health and disease, and in the operation of every hygienic and therapeutic remedy.*

Again, in these phenomena of altered functions and the greater one of the circulation, of which these are merely the expression, that mainly implicate what Sir Thomas Watson has so happily termed the "hydraulic machinery" of the body, we have not only a forcible example of the universal reign of law, a proof that mechanico-vital laws are as dominant in the animate as are purely physical ones in the inanimate world, but also a notable instance of a physical force originating, controlling, and modifying different kinds of vital processes.

The effects of heat on the human frame find a curious and instructive parallel and analogue in some of the greatest and most beneficent operations of nature in the inorganic world, thereby proving that heat is as important a physiological and pathological as it is a physical force. Thus, the heat which emanates from the sun, one of the greatest of all motive powers, influences the surface of the earth we inhabit very much as the self-generated caloric acts on the human microcosm which makes it. Acting on the sea and the air near the equator, their heated and thereby lightened particles rise and overflow to form those great and beneficent winds, ocean-currents, and rain-deposits, so important in the sanitary as well as in the social economy of the globe. So, in similar circumstances, or in artificially-formed tropical atmospheres, the blood flows from internal parts towards the finely-divided surface capillaries, to produce equally great and vital changes in the human economy. In all three the *agent*, a physical one, is the same, namely, *heat*. In all three it acts in the same way, namely, as a *vis a fronte* or attracting force. And while solids, liquids, and gases are alike acted on, the *manner* in which this is usually effected corresponds, the latter three or vivifying air, ocean, and watery vapor in the one case, and the life-sustaining blood in the other, being directly influenced, the solids being only indirectly and in a minor degree affected by and through these. The *parts* primarily acted on are the same, namely, that nearest the heating agent, the thin upper layer of water, the lowest stratum of air, and the cutaneous surface or shallow waters of the human circulation. The *primary effects* are the same, namely, a change in the direction of original currents. The *final results* are the same, namely, purification of the air, ocean, and body, and modification of their temperature. And the *ultimate objects* in all are identical, namely, hygienic and therapeutic, the promotion of the health and comfort of the different forms of life they severally sustain, that of the body nourished by the blood, and of the animals and plants which occupy the air and ocean. Without these phenomena of ocean-currents, winds, and blood-circulation, the heat of tropic lands and seas and the cold of other regions would soon become intolerable, and those of the skin and body either too high or too low for the maintenance of their vitality, while all three, the air, ocean, and blood, would rapidly become impure and unfit to sustain life.

The law thus induced by thermometric changes in the air proves that heat, long included in the category of therapeutic agents, is among the most potent of them all, inasmuch as it acts not slowly and on one organ or function, but promptly, certainly, and largely on every part, and stimulates not only their ordinary but also their vicarious or compensatory action. The effect of heat on the frame also finds its parallel in the action of certain medicines which apparently act on the circulation either directly or indirectly through the nervous system, thereby sending the blood to certain organs or parts in larger quantities than at other times. Thus, sudorifics, like heat, cause a diversion to the skin, diuretics to the kidneys, sialagogues to the salivary glands, galactagogues to the mamma, emmenagogues to the uterus, and so forth.

The recognition of these facts and of the law on which they depend, moreover, gives a firm and philosophical basis for the

* See two valuable papers on "Cold and Heat," by T. Wilkinson King, Esq., London Medical Gazette, June 23 and July 21, 1843.

further elucidation of the effects of these important physiological factors, climate, season, and weather, regarding which many points still need inquiry, of not more interest in a purely physiological point of view than in what may be termed ethnological or racial physiology, and in the solution of the long-vexed and still unsettled question of the unity or plurality of species, and the original development of man from one or several genetic centres.

Those physiological facts are necessarily of most value which are of practical application in the prevention, relief, or cure of disease. Hence the present subject is of etiological and semeiological importance. And in warm seasons or in tropical climates how can we properly estimate whether or not observed phenomena are pathological till we fully understand the physiological or healthy effects of high natural temperatures? Evidently, therefore, the study of the latter is the first step towards an accurate acquaintance with and philosophical method of treating or preventing many morbid processes.

The preceding facts are of *hygienic* and *therapeutic* value, and form a fitting preliminary to an inquiry as to the preventive, curative, or palliative effects of the same potent physiological agency in disease generally, especially in *lung and chest ailments*. And they not only give a clue to the rationale of the action both of those agencies heat and cold, and of many other frequently-employed remedies, but also furnish an indication for the application of these as prophylactic and curative media.

Lastly, as has been already shown, these facts materially aid in the diagnosis of lung ailments by furnishing a more accurate system of spirometry.*

To conclude, the following may be given as a summary of the more important of the preceding facts and inferences resulting from change of climate, season, or ordinary weather-fluctuations, when the thermometric rise is from 42° to 83° Fahr., or the reverse.

1. An increased spirometric capacity of the lungs to an average of 12¼ per cent., or 31 cubic inches, equivalent to a reduced vascularity by 17.88 fluidounces.

2. A diminished respiratory function, as shown by a slower respiration to the extent of 8.9 per cent., which combined phenomena diminish the amount of air consumed daily by 36.85 cubic feet, or 18.43 per cent., of carbon excreted daily by the same percentage, or 1.843 ounces, and of watery vapor excreted by the same percentage, or 4 fluidounces, nearly.

3. A diminished pulse by two and a half beats per minute, and perhaps a reduction in its force also.

4. An increased body-temperature by from 1° to 2° Fahr.

5. A diminished urinary secretion by 17½ per cent.

6. An increased perspiratory secretion to the extent of 22.38 per cent., and perhaps a correspondingly-increased elimination of carbonic acid by the skin.

7. A diminished hepatic secretion to the extent of 0.15 per cent.

8. A diminished weight of the body in the majority, and a like impairment of the physique, often to the extent of 64 per cent. and average of five pounds.

9. Retarded growth in the majority of youths.

10. A correspondingly-increased supply of blood or vascularity of certain of the involved organs, and a similarly-diminished turgescence of others, according as their function is increased or diminished.

11. Phenomena of an exactly reverse kind, and to a like extent, on making an opposite change of temperature,—namely, from heat to cold.

12. A corresponding fluctuation, both in vascularity and function of corresponding organs, after each successive change of temperature.

13. The occurrence of similar phenomena as a result of change of *season*, and also of the ordinary *weather*-fluctuations prevalent everywhere.

14. The occurrence of like results, and from a like cause, from change of *altitude*.

15. The dependence of one and all of these phenomena on a definite cause, which may be termed the *climatic law* of the circulation, by which internal organs are congested at the expense of external ones under the influence of cold, and external ones congested at the expense of internal ones under heat.

16. The greater extent of these phenomena in adults and persons of large frame, and that for an obvious reason, the greater bulk of the blood.

17. The existence of a certain range in this redistribution of the blood and the

* See the Pacific Medical and Surgical Journal for August, 1879, and May, 1880.

resulting functional and morphological changes, which varies according to size, age, sex, and individual peculiarities, and beyond which they become pathological.

18. This physiological rise and fall, especially when great, as during zonal migrations, tend to increase both the ordinary and the vicarious action of the different involved organs.

19. The climatic law and its results affect the white and the black race, and therefore, presumably, every other race and variety of mankind, though each, doubtless, has its physiological differences.

20. They likewise manifest themselves in all latitudes and climates, in every change of season, and even during local variations in the weather.

21. In all cases, whether from climate, season, or weather-changes, the primary and essential cause of these physiological phenomena is *change of temperature.*

22. As the aërial temperature is everywhere and at all times varying, so these physiological phenomena are not only of universal occurrence, but also in more or less constant progress in every individual over the entire face of the globe.

23. Temperature being their exciting cause, they necessarily vary with this in extent, and therefore may alter as greatly and much more speedily within the twenty-four hours of the day than they do during a more slowly accomplished change of season or zone.

24. Their ultimate object in health is hygienic.

25. Seeing that they are as evident in morbid as in healthy states of the frame, they may thus act, according to circumstances, as therapeutic agents, or the reverse.

MYELOID SARCOMA OF THE TIBIA.

BY HENRY M. WETHERILL, M.D.

KATE S., æt. 20, single. Admitted to the surgical ward of the Pennsylvania Hospital, under the care of Dr. R. J. Levis, January 27, 1880.

She gave the following history. Her father died of phthisis; her mother about two years previously had been successfully operated upon for an external tumor, and her brother had at the time a large one upon the back. A few months after a fall and contusion of the right knee, the patient noticed a small, firm tumor just below the right patella, which has gradually increased in size, and for the past six months has been the seat of severe lancinating pains. Menstruation, which before was quite regular, during the past year has been almost absent. Upon admission, the patient was pale, weak, and anæmic, and received tonic treatment. The tumor involved the knee, but seemed to spring principally from the head of the tibia, the growth being principally forward. The circumference of the tumor over the head of the tibia was twenty and a quarter inches, and in length it was ten and a half inches. The knee was flexed at a right angle, and anchylosed. The tumor was pale, smooth, somewhat elastic, and rather painful when handled, with enlarged, tortuous, superficial veins, cystic in character. The inguinal lymphatic glands of the right side were slightly enlarged and indurated.

Upon the 4th of February Dr. Levis amputated the limb at the middle of the thigh, making antero-posterior flaps. At the point of division of the femur the bone was much less consistent than normal, the saw almost dropping through of its own weight. Carbolized dressings and a drainage-tube were used. When the stitches were removed, February 11, it was found that the entire line of flaps had united by first intention, except at the angles, which were kept patulous by the drainage-tube, and by February 26 the stump had completely healed, and the patient was sitting up. Upon the 8th of March she complained of severe throbbing pain in end of stump, the line of cicatrization being tender, hot, red, and throbbing. She was ordered to bed, and sedatives applied to the stump; quinine and morphia given *pro re nata.* Upon the 16th a small opening made its appearance in the cicatrix opposite the end of the femur, and a probe passed through the opening discovered a tract two and a half inches in depth leading towards the femur; but no dead bone could be detected. The same treatment being continued to April 1, the three catgut ligatures, with the knots apparently as closely drawn as when applied, were at that time found upon the surface of the poultice. They were quite hard and tough, and looked like the stems of raisins. From this time the stump rapidly healed.

Remarks.—It would be unfair to the application of catgut in surgery to withhold the fact that the ligatures employed in this case had been unskilfully prepared, the solution of chromic acid in which they had been macerated being too strong,—a condition which never fails to render catgut very tough and almost imperishable, those discharged from this stump not being even softened after lying for months in contact with the warm, moist discharges.

EXAMINATION OF THE TUMOR.

The specimen shows a section through the centre of the tibia with its tumor, the knee-joint, and the femur. The tumor commences

on the tibia, five and a half inches below its articulating head. A transverse section of the growth measures five inches in diameter; a half-circumference, eight inches. The extreme length of the growth upon the fibular side is six inches. The anterior and posterior portions of the head of the tibia have been raised up by the growth, and extend like a cap around the articulating surface of the femur; but the articular cartilage appears smooth and normal, and in the recent condition the joint appeared without fluid. The entire surface of the tumor is covered with thickened periosteum and a thin shell of bone, the remains of the compact substance of the tibia.

At the lower portion of the tumor, where it meets with normal bone, the compact substance is much thickened by periosteal growth, and is spread out around the lower segment of the tumor like the cup-shaped receiver of a ball. Over the surface of the tumor were attached and displayed the tendons and muscles, the latter undergoing fatty degeneration. The surface of the section of the tumor shows a great variety of colors and consistence of its tissue, varying from a dense white to a dark blood-red, from solid meat-like masses to cysts of varying size filled with dark-red fluid. Microscopic sections taken from various portions of the tumor show it to be a myeloid sarcoma in which the myeloid cells are of small size.

Many portions of the tumor had almost completely undergone degeneration, leaving behind bands of fibres with no cellular elements; at other portions the degeneration was less complete, the spindle-cell element having disappeared, leaving, however, myeloid masses which were undergoing granular and fatty degeneration. A microscopic examination of the medullary substance of the tibia below the tumor showed it to be involved in the growth, the myeloid cells being abundant and large in size. The medullary substance of the femur is pale and fatty-looking, but there was no evidence of its involvement.

This case has been under observation for the past year, and has never suffered in any way since, enjoying better health than ever before. The stump is exceptionally free from pain, and is in excellent condition for the adjustment of an artificial limb.

1237 Arch Street.

TRANSLATIONS.

Action of Cantharidin.—At a recent meeting of the Société Médicale des Hôpitaux (*La France Méd.*, 1881, p. 223) Dr. Cornil read a paper on this subject, in which he said that when a rabbit is given cantharidin, either by the digestive tube or by absorption through the skin as by means of a blister, symptoms of poisoning are observed in the form of cystitis, nephritis, and inflammatory lesions of the liver and lung. Twenty minutes after the ingestion of the cantharidin the following lesions are found in the cavity of a glomerulus of the kidney: a large number of white blood-globules between the envelope of Müller's capsule and the vascular tuft composing the glomerule of Malpighi, together with a granular exudation filling and obliterating the calibre of the tubuli uriniferi. At the end of an hour these lesions are characterized by the proliferation of cellules, which, though they may at first have been round, are later irregularly multangular by mutual pressure. There is therefore true catarrh of the uriniferous tubules. In the bladder similar changes take place, but the lesions are superficial: it can be seen that the irritant principle contained in the urine acts directly upon the surface of the mucous membrane. A blister allowed to remain a long time in contact with the skin may produce the same effects, and Cornil is inclined to believe that the large blisters which are sometimes placed upon the chest, and are permitted to remain from twelve to twenty hours, do more harm than good. A blister should not remain on the skin more than three or four hours.

Treatment of Ménière's Disease.—Dr. M. E. Ménière (*La France Méd.*, 1881, p. 239) has recently published a brochure on the affection described in 1861 by his father and which has since been called by his name. The disease, as is known, is characterized by three principal symptoms: 1, noises or whistling in the ear, which precede the attacks; 2, vertigo accompanied by nausea and vomiting; 3, final deafness, which is usually incurable. Without going into a full description of the disease, Dr. Ménière the younger chiefly writes of the treatment, following the plan proposed by Prof. Charcot. The patient takes the following pill at meal-times: ℞ Quiniæ sulphat., Ext. cinchonæ, āā gr. jss. Beginning with this pill to the amount of about five grains of sulphate of quinine daily, the daily amount is increased to twelve or fifteen grains. Then no medicine is taken for from one to three weeks, and then the quinine is commenced again in the dose of six grains a day and continued for a month. The effect of the quinine is to diminish the vertigo and

finally to cause it to disappear entirely, modifying also to some degree the deafness. M. Ménière does not pretend to be able to formulate a cure for a disease in which all the resources of therapeutics have thus far proved vain, but quinine has at least the advantage of reducing some of the more severe symptoms.

ORANGE-COLORED SUPPURATION.—Verneuil (*Cbl. f. Chir.*, No. 5, 1881; from *Archives Générales*) says that orange-colored pus was first observed by Lebert in pyæmic patients, and later was stated by Delon to be pathognomonic of the pyæmic condition. Verneuil formerly agreed with these authors, his experience during 1870–71 having gone to show that severe wounds and fractures from bullets, particularly in intemperate persons, were likely to give rise to suppuration of this character, leading to a fatal conclusion. Recent observation has, however, led him to different conclusions. Orange-colored pus, which owes its color to an admixture of blood-coloring matter, is also observed in slight injuries which do not result fatally, but never before the third or fourth day, and not later, in a carefully-cleaned wound. The phenomenon is only very rarely observed, and usually when it does occur is ominous rather as showing a bad constitution on the part of the patient (alcoholism, phosphatic urine, etc.) than as indicating any direct tendency to pyæmia. A number of observations are given in support of this view. Riedel, of Göttingen, who translates Verneuil's article, says that his reasoning shows that he has not observed many cases of wounds dressed with careful antiseptic precautions, or he would scarcely have met with orange-colored pus on the third or fourth day (of a complicated fracture of the leg in a diabetic patient), under cotton batting, where there was at first no fever.

LARYNGEAL AND TRACHEAL STENOSIS AFTER TYPHOID FEVER. — Kiesselbach (*Cbl. f. Chir.*, No. 5, 1881; from *Deutsche Zeitschr. f. Chir.*) reports a case where gradually-increasing dyspnœa, coming on half a year after an attack of typhoid fever in a girl of 17, made tracheotomy necessary. In addition to marked inflammatory changes in the trachea, two elongated mucous tumors subsequently made their appearance in the posterior tracheal wall. Kiesselbach supposed that these were brought out by long-continued pressure of the canula against the edges of the tracheal wound, because they were seated on a spot directly opposite the tracheal wound and outside of the point of pressure of the posterior wall of the canula. The passage of tin bougies while removing the stenosis did not affect the tumors: so Kiesselbach had a canula made which contained a fenestra on the convex side, which was closed by a plate hinged below. The plate could be placed in position by a screw, and pressed against the posterior wall of the trachea. By the pressure of this plate the tumors were gradually caused to disappear.

INCREASED SECRETION OF SWEAT OF ONE SIDE OF THE FACE (*Giorn. di Med. Mil.*, November, 1880; from *Botkin's Archiv*, Bd. v., and *Peter's Med. Wochenschr.*, No. 39).—The patient, sixteen years ago, had suffered from parotitis as a complication of typhoid fever. The abscess was incised. Shortly after he noticed diminished sensibility of the skin anterior to the right ear, and redness of the right cheek when eating, which would, at the same time, be suffused with sweat. Careful examination revealed a cicatrix of no great depth behind the right ear; sensibility of skin anterior to the right ear slightly less than normal. The tongue, when protruded, deviated a little to the right; the right angle of the mouth was slightly depressed. On placing a little acid in the mouth, the right cheek at once blushed, was covered by profuse sweat, and increased in temperature. These phenomena occurred also on simply masticating, nothing being in the mouth. The bare idea of an acid provoked the same conditions.

Atropiæ sulph. (dose not mentioned) diminished the secretion of sweat, but had no effect on the rise of temperature and the blush.

From the above, the author concludes that the secretion of sweat is independent of vaso-motor influence, and directly dependent on special sudorific centres and particular nerves which supply the sweat-glands. J. F. W.

CURE OF OZÆNA BY IODOFORM (*Giornale di Med. Militare*, October, 1880; from *Allg. Med. Central-Zeitung*, June 5, 1880, and *Allg. Wiener Med. Zeitung*, No. 30, 1880).—Dr. Letzel prescribes iodoform, mixed with gum Arabic, so as to form a smelling-powder, in the proportion of two grains of the former to ten of the latter;

from three to six of the powders to be used daily. In six cases of ozæna so treated, the result was extremely satisfactory. In two of these, which had been under various treatments for two months, this effected a cure in from ten to fifteen days. In the other four cases, which were less serious, a cure resulted in six to eight days. Before administering the powder, the nasal douche is to be used. J. F. W.

A Characteristic Symptom of Hereditary Syphilis.—Prof. Parrot (*Le Progrès Méd.*, 1881, p. 125), in a recently-delivered lecture on infantile syphilis, speaks of a particular condition of the lingual mucous membrane, first observed by Gubler and Bergeron, and described by Bridoux in his thesis (1872), and which the lecturer considers to be connected with and characteristic of hereditary syphilis.

The tongue displays desquamation, beginning at the point and the borders, and passing over the surface, the process reaching the central raphé (V *lingual*) by the time reparation is beginning at the border. The circinate form of the desquamation, and its clinical character of proceeding by rapid and successive assaults, recommencing, for example, at the point of the tongue in the newly-formed epithelium, before it has fairly begun to disappear at the base, serve to make this peculiar affection of the tongue in hereditary syphilis an entity not likely to be mistaken for any other affection of this organ.

Histological examination shows, in perpendicular section of the lingual mucous membrane, that there is a tumefaction of the cellular elements of the papillary layer, with superficial shedding of epithelium and proliferation of embryonal elements, as in the cutaneous syphilides. Another proof of the syphilitic character of this affection is found in the fact that its maximum of frequency is at the same age as that of the other syphilitic manifestations. Prof. Parrot does not regard this lesion as contagious, nor does he consider it amenable to treatment.

Extirpation of the Pneumogastric Nerve with a Tumor of the Neck—Recovery (*Giornale di Med. Militare*, November, 1880; from *Bulletino d. Scien. Med.*, October, 1880).—Dr. Lücke reports the following case. In 1878 he extirpated a colloid cancer, situated in the right submaxillary region, from a woman 29 years old. Two years later the patient returned. The disease had appeared in the cicatrix of the former operation, and a larger tumor of the same character was discovered beneath the right sterno-cleido-mastoid muscle, to which it closely adhered. No cachexia.

The tumor situated in the old scar was readily removed; the other, laid open by a longitudinal incision, was found to adhere closely to the internal jugular vein, and to be intimately associated with the pneumogastric nerve of this side. Twelve centimetres in length of the latter were removed with the cancer. Immediately following lesion of this nerve *no* change in pulse or in respiration was observed. The patient did well, and five months afterwards the pulse and respiration were found to be normal. J. F. W.

Hemorrhage in Esmarch's Process (*Giornale di Med. Militare*, November, 1880, p. 1192; from *Gazette des Hôpitaux*, No. 107).—M. Nicaise has made some observations on the temporary ischæmia and subsequent hemorrhage after the use of Esmarch's bandage in amputations. To obviate this difficulty, the writer proposes, after the operation is completed, and before removal of the bandage, that sponges be applied to the surface of the wound and the flaps drawn over these in such a manner as to produce a compression over the whole of the wounded area. Then the bandage may be taken off. When the skin has resumed its natural color, the flaps should be raised, the sponges taken out, and any bleeding vessel ligated.

Treatment of Keloid by Scarification.—Dr. Vidal presented before the Société de Chirurgie (*Bull. Gén. de Thérap.*, vol. i., 1881, p. 136) a man of 48, suffering with keloid and under treatment by scarification. Emplastrum de Vigo, douches, etc., had been of no avail, and the tumor gave rise to considerable pain, for which multiple scarifications in parallel and transverse lines were practised. To M. Vidal's surprise, the tumor became very much reduced in size, and the success gained in this case encouraged him to try the same procedure in other instances, which also resulted favorably.

Interesting Case of Smallpox in a Fœtus (*Giornale di Medicina Militare*; from *Bulletino delle Scienze Mediche*, September, 1880).—At a meeting of the Academy of Medicine, in Paris, Labbé

presented for Vidal a fœtus which had been born alive covered with smallpox pustules. The mother had been vaccinated when a child, and never had the disease. The pustules at time of birth seemed to have reached their seventh or eighth day; larger than the pustules of ordinary smallpox; well umbilicated. The child died in a few hours.

At about the time of conception of this offspring the father was suffering from semi-confluent smallpox.

PURULENT INFECTION IN TYPHOID FEVER—OBSERVATIONS OF DR. GANDY (*Giornale di Med. Militare*, November, 1880; from *Journal de Méd. et Chirurg. Prat.*, November, 1880).—Metastatic abscesses generally occur in the lungs, less often in the spleen, and then in the liver. Purulent infection generally follows an external eruption, but it is not necessary. This does not usually manifest itself before the third week, during the reparation of the ulcerated intestinal follicles, and it may be delayed until the second month. An eruption of ecthymous pustules should therefore be carefully noted.

Metastatic abscesses of the lungs can be recognized by auscultation and by dyspnœa; of the liver, by the jaundice. Chills, a rapid rise of temperature, often profuse sweats, the state of the tongue, diarrhœa, eruptions, such as of boils, or miliary, ecchymoses, all confirm the diagnosis.

Believing that infection is due to the absorption of purulent matter from intestinal ulceration, the writer recommends phenicated laxatives. Dr. Bouchard advises a mixture of glycerin and carbon, or the following: creasote, gtt. ii; rum, 120 grammes; phenic acid, 25 centigrammes; salicylic acid, 1 gramme. J. F. W.

THE DERIVATIVE VASCULAR ACTION OF LARGE DOSES OF IPECAC IN PNEUMONIA.—Dr. Verardini (*Jour. des Sci. Méd. de Louvain*, 1881, p. 100; from *Bull. delle Sci. Med. de Bologna*), basing his investigations on those of Pechollier, Peter, and others, gives ipecac to his pneumonia patients in thirty- to eighty-grain doses. He has not found it useful in hæmoptysis, but it appears to be valuable in diminishing pulmonary hyperæmia and congestion, and to be susceptible of producing a sufficient degree of ischæmia to ameliorate considerably the condition of patients suffering with pneumonia. He formulates his conclusions as follows. 1. Ipecac is harmful in hæmoptysis. 2. It is useful and well tolerated in pneumonia. 3. The ischæmia induced in the lungs under the influence of ipecac appears to be the result of its reducing vascular tension. 4. The beneficial effect of the drug is not dependent upon the nausea and vomiting which it produces, but to this reducing action. 5. This action of ipecac has been shown by experiments made by the author.

TO FACILITATE THE REMOVAL OF PLASTER-OF-PARIS BANDAGES.—Dr. Mooy, of Holland (*Jour. des Sci. Méd. de Louvain*, 1881, p. 93) recommends that before the application of the plaster bandages a band of flannel should be laid up and down the limb at the point where the plaster bandage is to be divided. This is to be doubled, and saturated with unboiled linseed oil to which has been added five per cent. of carbolic acid. At the end of a few hours the bandage is found to be impregnated with oil, as is testified by the yellow color which it assumes along the course of the flannel band. Dr. Mooy adds that the flannel band is not absolutely requisite, since the same object may be gained by oiling the plaster bandage from the outside, either after it has dried or while it is being put on.

DELIRIUM TREMENS CURED BY CANNABIS INDICA AFTER THE FAILURE OF OPIUM AND CHLORAL.—Dr. F. Villard (*Le Progrès Médical*, No. 8, 1881) gives a case in which eighty grains of chloral were given within ten hours without producing rest, and then extract of opium to the amount of two to three grains, also without result. Extract of haschisch to the amount of two grains every hour until eight grains had been taken gave relief. This dose, which is about four times that recommended in the books, was given because, as Dr. Villard says, a smaller dose—or, at least, too small a dose—would have produced a stimulant instead of a narcotic effect. He lauds the effect of the cannabis very highly.

SACCHAROCARBONATE OF IRON.—M. Ch. Tauret (*Bull. Gén. de Thérap.*, vol. i., 1881, p. 127) has discovered a crystallizable compound of carbonate of iron and sugar, to which he gives the above name. It is found in the interior of Vallet's mass after two years, and contains eighteen per cent. of carbonate of iron. It is easily soluble in feebly acid solutions.

EDITORIAL.

THE COUNTY MEDICAL EXAMINERS.

AT the meeting of the Pennsylvania State Medical Society held in Pittsburg, May, 1878, Dr. A. M. Pollock, of that city, offered a resolution which required all county medical societies, represented in the body, annually "to elect three members, to be called medical examiners, whose duty it shall be to examine all applicants for admission as students of medicine under the tuition of members of this Society; and said committee shall withhold their certificate from any applicant unless he is of good moral character, possess a good English education, and a sufficient knowledge of Greek and Latin to enable him to pursue his studies with advantage. And no member of any county society shall receive any person as a student of medicine unless he presents a favorable certificate from this committee." After a good deal of discussion, this resolution was adopted and entered upon the minutes.

At the meeting of the Society held at Altoona, last May, it was officially made known that a large number of county medical societies had failed to comply with the resolution, and a second resolution was carried by a large majority, that no delegate should be received at the meeting of 1881 from any county medical society which had not "complied with the law requiring the appointment of medical examiners." The Philadelphia County Society has, we believe, refused to so comply; and the interesting question arises, Will its delegates be excluded? To our thinking, it is perfectly plain that they will not be, and cannot be.

The constitution of the Pennsylvania State Society avers (Article III., Section 1), "The Society shall consist of delegates and permanent members." (Section 2.) "The delegates shall receive their appointments from the county societies." (Section 3.) "Every delegate from a society not in delinquence, before admission to a seat in the Society, shall produce a certificate of delegation signed by the president or secretary of his county society, and shall sign the rules and regulations." What the words "rules and regulations" mean is nowhere explained, either in the constitution or the by-laws, and it is probable, therefore, that no legal meaning attaches to the phrase. It is plain, however, that they must refer to something personal to the delegate, and not to anything affecting directly the county societies, since the constitution gives the society the right to representation, provided the annual dues have been paid, and any rule or regulation depriving the county society of such right would be unconstitutional, and therefore null and void.

Further argumentation does not seem necessary. It is plain that the resolution of 1881 previously quoted is unconstitutional, that its passage was a legislative blunder unworthy of those who adopted it, and that if the Society desires to enforce the provisions of the first resolution (that of 1878) it must do so by altering the constitution in the manner prescribed in Article VIII. of that instrument. A second and very important consideration which now arises is, Is it better for the State Society to attempt coercion in the future?—*i.e.*, to alter the constitution according to constitutional methods, and then exclude defiant county medical societies.

It is plain that if it were possible to keep the uneducated from entering the profession the gain, both to the profession and to the country, would be great. It is also plain that the enforcement of such a

resolution as that proposed would be very influential in leading young men to educate themselves primarily before attempting to study medicine. The end is most desirable; the method of obtaining it is efficient, provided the State Society has the power to enforce its own will.

That our State Society yearly adds new rivets to the bonds with which it unites practitioners of medicine into a corporate body is unquestionable; and it does seem to us as though this great body might now begin to exert its powers. The present outlook indicates that if it does there will be a trial of strength between it and the Philadelphia County Medical Society, led by a few men whose vested interests are not exactly those of the profession. Do our rural brethren doubt as to who, under these circumstances, would, in the long run, win? A change of leadership might result in our city councils; or the counsels might change, the *personnel* of the councils remaining the same. Something would give way, provided the State Society acted firmly, wisely, and not overbearingly,—acted, in other words, in such a way as would conform with the self-respect and sense of justice of a large majority of its members.

The resolution of Dr. Pollock should, however, before being put into the constitution, be modified in obedience with the maxim that all statesmen recognize,—namely, to proceed by short steps. Neither the general community nor the general profession are prepared to require a knowledge of Latin and Greek of the candidate for medical honors. A man may be highly educated in science and know neither Latin nor Greek: indeed, it is doubtful whether the study of Greek ought even to be encouraged, when modern languages and physical sciences offer so much opportunity for useful work as they do at present. The standard-bearer who rushes away ahead of his regiment dies and accomplishes nothing: such is the natural fate of courage without brain. The useful flag-carrier is he who so slowly bears it onward that the regiment does not know when to forsake its standard, and with it swarms over the enemy's entrenchments or lines. We hope that at the approaching meeting of our State Society some one will offer an amendment to the constitution requiring the appointment by the county societies of examiners, who shall see that every would-be student of medicine has received a good English education and has some elementary knowledge of the physical sciences. If this is finally adopted, we can hope for good to be achieved.

UNDER the name of the *Medico-Chirurgical College of Philadelphia* a new medical school has been born. To our thinking, it is an ambitious, even if puny, youngster. Even the babe in the cradle is beginning to spew at the mention of an eighteen months' course of medical study! The requirements, fees, and announcement seem to be modelled after those of the University. Where the pap to sustain the budding life is to come from is not plain to an outsider. A two years' college with low fees might, we believe, be made a pecuniary, although discreditable, success in this city; but what sufficient inducements are offered to students between the pink covers before us we are unable to discover. As there appear to be no trustees in this new venture, the faculty is untrammelled to do what it likes, and when the pressure of unpaid bills, rent in arrears, etc., is felt, we fear lest Bellevue shall have an imitator.

It is also stated that a new medical college has been started in Pittsburg. We have seen no announcement, but suppose the statements are correct. Poor Pennsylvania! *O tempora! O mores!*

PROFESSOR CHARCOT is said to have received recently twelve thousand roubles (about nine thousand dollars) for a consultation visit to Moscow.

LEADING ARTICLES.

THE CATGUT LIGATURE.

THE catgut ligature appears likely to play a not unimportant rôle in the surgery of the future. Its advantages over the old-fashioned silk ligature are, in some respects, so decided that its advocates, undeterred by occasional failure, continue to push its claims and to experiment continually with a view to remedying its defects and improving its good qualities. The subject has, indeed, been regarded as so important by Prof. Lister that he has taken it as his text on the occasion of his installation as President of the Clinical Society, and has devoted his inaugural address* to an examination into the qualities of this ligature and the methods of its improvement.

Contrary to what was originally apprehended with regard to the catgut ligature, it is found to disappear entirely, even when suppuration takes place in the wound. It does not, when well prepared (unless under exceptional circumstances), come away like a little slough, as was feared. Now and then, however, in the experience of some surgeons, the knots of the catgut ligature have given way, leading to severe hemorrhage; or suppuration around the ligature has taken place, with great delay in the patient's recovery. In the hope of preventing in some way these untoward results, various experimenters, and among them Mr. Lister, have sought for some method of making the catgut ligature not only effectually strong, but also unirritating.

Animal ligatures of another kind have recently been suggested by Mr. Barwell, —namely, strips of the mingled yellow elastic and unstriped muscular tissues which constitute the arterial wall, obtained by spirally cutting the aorta of one of the larger animals. The chief objection to these ligatures is the difficulty of obtaining them: for the average surgeon's use so unusual a material is not convenient. Catgut, on the other hand, may be obtained all the world over in abundance. As it comes from the maker, however, it is entirely unfit for the purposes of the surgeon. It becomes soft and pulpy soon after it has been placed in blood-serum. A piece of catgut placed in warm serum from the blood of a cow assumes this condition within half an hour. It is essential, in order to fit the catgut for the purposes of the surgeon, that it be altered in its physical constitution so as to be no longer liable to this softening effect by the serum of the blood. It is a remarkable fact that blood-serum softens catgut more readily than warm water does; so that we cannot test the endurance of catgut by steeping it in warm water. Mr. Lister believes that his method of preparing catgut answers the purpose very well, provided certain conditions are complied with in its preparation. However, the process is a tedious one, requiring at least two months to make the ligature at all trustworthy. This is a serious objection, for the surgeon who has not prepared the catgut himself and kept it for a long time is at the mercy of the person who supplies it, and the person who supplies it, not being aware of the enormous importance of the question of time, if he happens to have run out of that which has been long prepared, will sell what has been only a short time in the preparing-liquid and is, in consequence, altogether untrustworthy.

Mr. Lister brings forward a new method of preparing the catgut ligature which is the result of experiments made during his leisure time for the past two years, and the account given in his lecture is interesting as showing the amount of careful investigation requisite to understand even so simple a thing as the manufacture of catgut. He has followed up the process of its manufacture from beginning to end, and, having first shown what the material is with which we have to deal, he goes on to speak of the necessity that the catgut should be "seasoned." But by the ordinary process this involves, as has been said, a long period of preparation. It is desirable that the period of preparation should be short. Then it is essential that the catgut should have proper strength, so as to bear any reasonable strain that the human hands can put upon it in the thicker forms, —as when used, for instance, in such cases as the circumferential ligature of the thyroid vessels, in the removal of a goitre, or for securing the pedicle in ovariotomy. And it is not sufficient that it should be strong to start with: it is easy to get catgut strong in the dry state: it is necessary that it should be strong after steeping in blood-serum awhile. It would be a very sad

* Lancet, vol. i., 1881, p. 201.

thing for the ligature of an important vessel if the residence of the catgut among the tissues soaked with serum for a few minutes, or even for a quarter of an hour, should render the catgut so soft that it should give way or permit the knot to slip. It is necessary that a knot tied upon it should hold with absolute security.

That catgut as at present employed does not fulfil this condition seems probable from the report of cases under the care of Messrs. Treves and McCarthy read before the Royal Medical and Chirurgical Society at a recent meeting.*

In Mr. Treves's case, which was particularly interesting, the right carotid in a case of aneurism was ligatured above the omo-hyoid with antiseptic precautions, and the wound healed by first intention. A month later the third part of the subclavian was ligatured, but, through some accident, suppuration took place. The patient dying one hundred and eight days after the operation, the ligated vessels were examined. In the region of the carotid no trace of wound could be discovered even in the carotid sheath, and every trace of the ligature had disappeared. No constriction could be seen in the vessel; its external outline was unaltered, and the seat of ligature was indicated only by a faint, transverse, bluish mark on the vessel, due apparently to the thinness of the arterial coats in that direction. The vessel was found to be patent, but to be narrowed at the seat of ligature by a kind of perforated diaphragm leaving a central aperture about a line and a half in diameter. This diaphragm was formed by the incurving of the ruptured ends of the middle coat. The ligated portion of the subclavian artery was found imbedded in a very firm mass of inflammatory material, and was occluded for three-quarters of an inch and entirely obliterated for half an inch.

The appearances here presented certainly seem, to us, to point to early solution of the ligature thrown around the carotid before inflammatory adhesion and the organization of the clot could have time to occur. Indeed, it would almost appear that ligature by catgut as heretofore performed must have been hap-hazard, and it seems almost wonderful that no cases of secondary hemorrhage have been reported. On the other hand, the opposite fault of too great toughness and resistance to the solvent action of the tissues is the commoner, thus resulting in suppuration, with the final rejection of the unchanged ligature, as occurred incidentally in a case reported by Dr. Wetherill in the present number of this journal.

Mr. Lister claims that by his new method of preparation the catgut ligature may be rapidly made ready for use, and that it may be made of just the desired degree of toughness and resistancy. His method is as follows. One part of chromic acid is dissolved in four thousand parts of distilled water, and to the solution are added two hundred parts of pure carbolic acid or absolute phenol. Minute as is the quantity of chromic acid, it exerts, when in conjunction with carbolic acid, a very powerful effect upon the gut. The first effect of the addition of the carbolic acid to the chromic solution is to change its pale yellow to a golden tint. Later, a gray precipitate falls; but this does not occur when the catgut has been immersed in the solution. As soon as the liquid has been prepared, an equal weight of catgut is introduced into it. If the proportion of catgut is too large, it runs the risk of not being prepared; if too small, it may be over-prepared. At the end of forty-eight hours catgut steeped in such a solution is sufficiently prepared. It is then taken out of the solution and dried, and when dry is placed in one-to-five carbolic oil; it is then fit for use, and will not soften in serum.

Such is the new method of preparing the catgut ligature, which is considered of such importance by Mr. Lister that his address is chiefly concerned with this subject. He also gives useful information regarding the preparation of the catgut itself, which we have not space to describe. As to the strength of the gut thus prepared, a bit two and two-thirds hundredths of an inch in diameter, after soaking in serum for half an hour, stood a strain of eleven pounds four ounces. Ten pounds, Mr. Lister says, represents the utmost strain that his arms are able to put upon a cord. The ligature is thus seen to possess ample strength.

With regard to the behavior of the new catgut among the tissues, Mr. Lister's experience is against the view that catgut is dissolved by the serum. Bits of it exposed to the action of fresh or of putrid serum

* Lancet, vol. i., 1881, p. 251.

remain undissolved. Catgut introduced into wounds is not dissolved by the serum, for when used as drainage those parts beyond the vital influence of the tissues remain unchanged, while those within gradually disappear. Microscopic examination of improperly-prepared catgut which has been in the living tissues shows it to be diminished in size and infiltrated with young growing cells. Good catgut, however, is merely eroded superficially, and is found to be thus gradually dissolved away, retaining its firmness to the last. Mr. Lister compares the absorption of the catgut to that of dead bone in a granulating wound. Erosion, however, does not begin at once,—indeed, not for a fortnight, according to Mr. Lister; and then it proceeds slowly, especially in the larger sizes of catgut.

Dr. MacEwen,* quite independently of Mr. Lister, has also devised a somewhat similar chromicized catgut, which was described in a late issue (March 12) of this journal.

CORRESPONDENCE.

LONDON LETTER.

IN a recent letter I considered the subject of the presence of lithates in the urine of cardiac dropsy, and their significance. They were regarded as indicating the inability of the liver to perform its function of the oxidation of albuminoids. The subject of the assimilation of albuminoids will now be further considered in their relation more especially to tissue-nutrition. This is a matter the practical importance of which is daily making itself more and more felt as physiologists are clearing up the functions of the liver. We see malnutrition in various forms. From lack of lime the bones are ill nourished, as seen in rickets; from want of sufficiency of fat in the tissues we get tubercle; when children cannot digest starch general malnutrition results; and when the albuminoids are deficient in the blood we find tissue-nutrition defective, and this is often very apparent in the heart and the diaphragm,—two muscles ever in action, and therefore feeling changes in nutrition very keenly. Strange it is that, with so many observers sweeping the field of physic for a subject to study specially, no one will look at the diaphragm; yet it must be affected by all conditions which interfere with the proper nutrition of muscles. The chest is examined with various instruments of precision, is percussed, auscultated, measured, and inspected; the calibre of the air-tubes, the question of the contraction of various areas, of pulmonary collapse,—all and everything seem to be examined except the condition of the diaphragm, whether it be fatigued or ill nourished, or otherwise. Yet surely much of the dyspnœa we see is due to failure in muscular fibrillæ of the diaphragm, just as palpitation is due in certain cases to exhaustion of the muscular structure of the heart. Starvation, then, of these two important muscles is one of the outcomes, and a conspicuous one in some cases, of the failure of the digestive organs to assimilate properly the albuminoids of our food.

It was shown in a recent letter that in digestion the proteids are changed into peptones by a process of hydration, and that when the peptones have, by so being made soluble, passed into the blood, they are dehydrated again. What is the precise history of albuminoids in the body until they reappear as the early histolytic products—leucin, tyrosin, creatin, and creatinin, passing on to bile acids and urine solids (the forms in which nitrogenized waste finds its way out of the blood)—is what we do not know, though it is what we very much wish to know. We have excellent grounds for holding that the liver has much to do with the furnishing of these albuminoids to the blood as required for interstitial digestion,—*i.e.*, the feeding of the tissues from the blood, as differentiated from feeding the blood from the food. The blood is fed first, and then from it the tissues. The relation of liver-disturbance to imperfect tissue-nutrition is a matter not nearly as much understood as it ought to be. The malnutrition which arises when the liver becomes enlarged secondary to mitral disease, the presence of lithates in the water, and the pale stools often seen, are common clinical phenomena. Yet it is quite usual, under such circumstances, to cram the patient with food largely albuminous, under the belief that such food is strengthening. So it would be if it were digested; but, then, it is not. On a dietary of fish and milk-pudding the patient would be much better nourished, because some of this food is fully and properly digested, while on a heavy meat diet the liver is simply overwhelmed and can digest none of it thoroughly. Of course the patients or their friends remonstrate at first against the insufficiency of the dietary; but the results calm them. When this mal-assimilation impairs the tissue-nutrition, and the heart and diaphragm feel the starvation, then a distinct series of symptoms, objective and subjective, are set up. These are the evidences of a feeble heart, impaired impulse, indistinct sounds, a readily-compressible pulse, palpitation with dyspnœa on effort, cold extremities, and tendency to syncope. The patient feels breathless upon effort, sighs, has vertigo, is depressed, is unable to think clearly or to

* British Medical Journal, vol. i., 1881, p. 150.

command his thoughts; the memory is defective; there is an absence of energy, and work becomes distasteful; there is irritability of temper, for the brain is not only ill fed, but is poisoned by the products of mal-assimilation. We all know the sense of energy, of buoyancy of spirits, given by a dietary rich in animal food when the normal products of healthy assimilation are present in the blood in fair quantity,—that sense of energy the Anglo-Saxon race so dearly loves. But when the products are abnormal, then there are the negative loss of proper pabulum and the positive symptoms of toxæmia,—of abnormal matters in the blood. Between the two the brain is at once starved and poisoned; it cannot work properly; the mental processes are interfered with; all seems gloomy and hopeless; there is more or less developed panphobia; everything wears its worst aspect; the whole field of life, indeed, seems spread over with Indian ink. The patient feels miserable and apprehensive, dreads that he or she is the victim of some occult insidious mortal disease, and is haunted with dread and suspicion. The vaso-motor system is disturbed, and alterations in the calibre of the arterioles lead to a damming of the blood in the arteries; the heightened arterial tension offers an obstacle to the ventricular contraction, and there are attacks of imperfect angina pectoris. Personally, I have not encountered actual syncope in these cases, but the patients often feel very like fainting. The *tout ensemble* of the case is closely like that of the fatty heart.

But then the fatty heart has quite a different set of surroundings, and it is this environment which must guide us in our diagnosis. There are the evidences of degeneration elsewhere, the greasy unctuous skin, the gray hair, the tortuous temporal artery, telling of atheromatous change, general and extensive, and the arcus senilis,—indeed, the general aspect of age, of senility, ordinary or premature. Now, of course, there may be such concomitants and yet the feeble heart may not after all be fatty. A case which was under my care many years ago forces itself upon my consciousness. There were the evidences of cardiac feebleness, objective and subjective, in an old man near eighty years of age. I feared fatty degeneration, and kept him very quiet. But in a few weeks he began to improve; his pulse grew steadier and less compressible; the heart-sounds became more distinct, and in time the symptoms and signs were those of a fairly hypertrophied ventricle, with a distinct aortic obstructive murmur. The old gentleman lived several years after this, but what the end was I do not know, not being in the neighborhood at his last illness. Here there was decided "heart-starvation," closely simulating fatty degeneration of the heart-walls, in a person where such decay was quite likely to be the case; and cases of similar character have been met with not infrequently since. The associations of these cases of "heart-starvation" are either work during the hours ordinarily devoted to sleep, or disturbance of the liver. Now, in a very thoughtful article recently in *The Practitioner*, Dr. Lauder Brunton, F.R.S., the editor, has described "Indigestion as a Cause of Nervous Depression." Here he has shown how the nervous system becomes enfeebled from the non-removal of waste, the product of that combustion which accompanies and is the physical factor of all energy, while at other times the depression is due to the presence of products of digestion not usually found in the general circulation. Indeed, the whole article demonstrates in a very instructive manner the aid physiological research can give to practical medicine. Anatomical research, without, as well as with, the microscope, has been rather depressing than otherwise, tending to demonstrate lesions against which the healing art is powerless. But physiological research is of the most inspiriting character, aiding us much in our efforts to be of use to our fellow-creatures. The products of disordered digestion are then nerve-depressants, and consequently we see the nerve-centres are depressed, as well as ill fed, in common with the rest of the tissues. The failure of power in the heart brought about by fatty degeneration of its structure is closely simulated by this palsying effect of the products of mal-assimilation. A heart not in its pristine structural integrity will feel the effects of such depressant agents even still more. Many a case of heart-starvation is diagnosed as fatty degeneration, and if the dietary and treatment be not looked to the patient may actually sink from asthenia, sheer debility of the great centres. Some time ago I saw a case which bore all the evidences of a heart failing from fatty degeneration, yet its subsequent history makes me feel very doubtful as to the absolute accuracy of the diagnosis. Of course it is impossible to be sure about what is actually going on in the fibrillæ of the heart, whether there was pure "heart-starvation," or whether there was not some actual degeneration in certain fibrillæ, and that repair is taking place by the development of those embryonic muscular fibrillæ found within the sarcolemma which undoubtedly take the place of effete fibrillæ in the acute softening of the heart so common after sharp fevers. Whether or not, there is no manner of doubt about the improvement in the case, the recovery of power, the disappearance of the restlessness, with failure on effort, the dyspnœa and palpitation on exertion: indeed, there is general improvement of the patient. Now, here, the aspect at one time looked like that of fatty degeneration, and so it was regarded by other physicians who saw him previously to myself. Yet I am beginning to question the accuracy of our diagnosis, and venture to think

we may all have been mistaken after all. Unless the coronary arteries are so atheromatous that their lumen is reduced below that possibly compatible with the nutrition of the tissues of the heart, or their orifices are blocked with an atheromatous tubercle, I must confess that there does not seem any absolute impossibility of such repair taking place by the development of these embryonic fibres, as seen in the plates in my work on the "Diseases of the Heart," copied from the work of Rindfleisch, and which are most suggestive and incitive. The whole subject is most entrancing, especially now when we are beginning to be more familiar with the heart as a muscle, influenced, like other muscles, by the laws of nutrition and repair. Valvular diseases are now generally well recognized, but the varying conditions of the muscular walls of the heart are far, very far, from being well understood. We all are familiar with cases where slight signs of disease in the heart are quickly followed by fatal consequences. Are we anything like so familiar with the opposite class of cases, where the diagnosis and prognosis have been disproved by the work of time, and the condemned patient has lived to have his jibe at his doctors, perhaps even to follow them to the grave, while he lives on working and feeling well? These cases are not so rare as might be imagined. We know the danger of some matters about the heart. Shall we after a while begin to have some glimmerings of acquaintance with repair from conditions in which fatty necrosis has been closely simulated, nay, has even perhaps existed to some extent?

Now, the importance of the recognition of "heart-starvation" is not confined to clearing a number of cases of cardiac asthenia from the haunting suspicion of fatty degeneration in persons of middle age, and so saving much human misery which would otherwise exist. It has wider relationships. It enables us to recognize the precise nature of some otherwise troublesome cases of pronounced dilatation coming on quickly in persons previously quite well. For instance, about a year ago I was called in consultation to see a woman of thirty-six, a strong, healthy, vigorous woman, who had charge of a family of children all of whom had scarlet fever in turn. Night and day she assiduously tended her little charges, her affection for them causing her to stick to her duties until the last one was convalescent, when she was thoroughly "knocked-up" and had to go home to be nursed herself. Her mother, a hale woman of eighty, was bustling about, waiting upon her, showing that she came of a long-lived race, retaining their energies till very advanced age. The father I did not see. Here the heart had yielded under the tremendous strain put upon its walls, weakened and ill fed; for she gave herself no time for food, but just kept herself up by tea, and scarcely slept. She felt much better for the confinement to bed, and improved considerably under a course of digitalis and iron. I gave a very favorable prognosis. The last time I saw the medical attendant he told me she was dead. She had been taken into some hospital; but he did not know the particulars. It seems most likely that she sank under some intercurrent affection, as, with her family history, recovery was apparently only a question of time. "Heart-starvation," the consequence of loss of sleep and little or no food, may result in dilatation, which I think is more apt to be the case with women. At other times there is no perceptible increase in the area of cardiac dulness, and the symptoms are those of asthenia, only closely simulating the signs and symptoms of the fatty heart, and the real state cannot be distinguished by physical examination alone.

Now, what are the indications furnished for the management of these cases? In the first place, rest, as absolute as can be attained, must be secured. Any demand upon the heart would be very likely to originate acute dilatation. To reduce the demand upon the heart is clearly the first thing to be done. The next is to look to the assimilative processes. The bowels must be regulated; if there be lithates in the water, pale stools, and a bitter taste in the mouth, then an hepatic stimulant—sulphate of soda, ipecacuanha, iridin, or euonymin—must be added to the laxative employed; and the patient must be dieted. The question of diet is one of the extremest urgency in these cases. A small quantity of easily-digested albuminoids, fish, poultry, game, or milk-puddings, gives much better results than a heavy meat dietary, none of which is thoroughly digested. This is a matter upon which insistence is requisite. We must feed the patient so as to feed the blood, and from it the tissues. A little readily-digested food is thus properly assimilated, and then the nutrition of the albuminoid body-tissues follows. If the digestion is imperfect, it is easy to give a teaspoonful of the liquor pancreaticus advocated by Dr. William Roberts, in a solution of bicarbonate of soda, about two hours after a meal, at "the tail of the digestive act." This line of management will give good results. I do not know whether the dietary is as much attended to in the United States as it is here in England, or not. But with us we find in an appropriate dietary a great factor of the successful treatment of cases of malnutrition, no matter whether it is "heart-starvation" from imperfect assimilation of albuminoids, or "nerve-exhaustion" from the digestive powers being unequal to the building up of the complex fat "lecithin" containing nitrogen and phosphorus, or anæmia from their inability to construct hæmoglobin, a very complex body indeed, for the red corpuscles. The system may be equal to producing ordinary albumen

and fat, and yet be unable to build up these complex bodies. The subject of nutrition, especially "interstitial digestion," is one of which we are only beginning to conceive the practical importance, but a wide vista seems opening up. I have some emulsions of oil before me as I write, of considerable promise.

J. MILNER FOTHERGILL.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

AT a conversational meeting of the Society, held at the Hall of the College of Physicians, Philadelphia, January 12, 1881, Dr. Albert H. Smith, President, in the chair, Dr. Frank Woodbury read a paper on "Some Clinical Phases of Poisoning by Alcohol" (see page 417).

DISCUSSION.

Dr. E. T. Bruen noticed the similarity between the brain-symptoms of chronic alcoholism and those of ordinary chronic meningitis, and inquired regarding the differential diagnosis. He had observed in many cases of alcoholism irregular rises in temperature, and after death thickening of the membranes, adhesion, and other evidences of inflammation.

Dr. R. S. Huidekoper related a case of idiosyncrasy in regard to the effects of alcohol. While on a boating-excursion, a young man took within fifteen minutes a couple of drinks of whisky amounting to less than two ounces in all. In a short time his face became much flushed, and suddenly grew very pale; he then fell into a state of complete alcoholic coma. It was nearly six hours before he regained consciousness. It was subsequently ascertained that this gentleman had suffered on previous occasions from similar small quantities of alcohol.

Dr. John B. Roberts said that the physician has better opportunities of recognizing the effects of alcohol, and of studying the relations of cause and effect in alcoholism, than in many other diseases. The question whether or not alcohol is a true food is a very important one. Dr. Parkes, in his report of the issue of a spirit ration in the Ashantee campaign, arrived at the conclusion that for forced marches of short duration, especially at night, the troops did better on a rum ration, but that their energies were depressed the next day and they were correspondingly incapacitated from sustained effort; but on an extra ration of beef-tea their efforts could be kept up to the maximum for several days, with less fatigue.

Delirium tremens is not always due to deprivation of alcohol, but in many cases it is due to cerebral anæmia from want of food. It is not, therefore, to be regarded as an indication to return to alcohol-drinking so much as it is to administer nutritious food. In many cases tonics can be substituted for spirits, and the cases recover as well or even more readily than with whisky.

Dr. Charles K. Mills said that he regarded the remarks of the lecturer upon the differential diagnosis of acute alcohol-poisoning as of considerable importance. His own experience had been that it is very difficult to make an exact diagnosis of alcoholic coma. The points mentioned in the paper were good, but they would be insufficient sometimes to decide the character of a case. Hemiplegia, for instance, is not always present in apoplexy. He had seen a case lately where a large hemorrhage had broken down part of the cerebral hemisphere and the septum between the ventricles, both sides of the body at the time of examination being about equally helpless. In another case where coma was present it was difficult to decide whether it was uræmic, alcoholic, or apoplectic. The man was brought into the hospital ward insensible. Respirations were very slow,—indeed, only about one-third of what they should have been in health. The skin was so cold that surface-temperatures could not be taken with ordinary instruments, and in the rectum the temperature was under 90°. Complete paralysis existed, not hemiplegia. There was no odor of alcohol on the breath; no appearance of injury to the head; no swelling of the feet and legs. Albumen was present in the urine. Upon making the autopsy, cerebral œdema was found; a large amount of fluid was present between the pia mater and entire convexity of the brain; it was also increased in the ventricles. The kidneys were degenerated. It was a case of uræmia.

While in exceptional cases a positive diagnosis could not be made, still the presence of an alcoholic odor of the breath, the chemical examination of the urine, the surface-temperature, and the paralytic symptoms would largely guide us to a correct conclusion.

In reference to the treatment of acute and chronic alcoholism he endorsed the remarks of the lecturer. He had found in coma and threatened collapse that the expedient of administering belladonna or atropia hypodermically might be a most important one, and it was one that was not as largely used as it should be. It is especially valuable where death is threatened by respiratory paralysis. He had used atropia in this manner, combined with electricity, as a peripheral stimulant. He mentioned the following case, although not one of alcoholism. A patient had been almost constantly vomiting for nearly three weeks, with extreme depression of respiration, the movements being reduced to four or five in the minute. Under the use of electricity to the limbs and atropia hypodermically, she rallied from this condition and lived four or five weeks, when she had another

attack, in which she died. It was subsequently found that she had a cerebellar tumor. In nearly all the cases that he had examined of chronic alcoholism he had noticed changes inflammatory in character, especially in the pia mater; a peculiar opacity was usually present; but the pathological condition was not identical with that of meningitis from ordinary causes. He had also seen pachymeningitis in drunkards.

Dr. W. H. Parish, as illustrating the difficulties of diagnosis, referred to a case which had occurred at the Philadelphia Hospital. A man, who had been several times previously under treatment for a similar condition, was admitted into the drunk ward, moderately intoxicated. After some hours' rest he apparently recovered, and was employed about the institution for several days. One night he was taken with what was supposed to be mania dependent upon alcoholism, and he was treated for several days for delirium tremens. His death occurred shortly afterwards, and at the post-mortem examination the blade of a pen-knife was found imbedded in the middle of the brain, having entered through the squamous portion of the temporal bone; the whole blade was there; it had led to extensive abscess, meningitis, and cerebritis. The symptoms throughout had been apparently those of delirium tremens.

Dr. Bruen said that he had seen cases in which he should have liked to have something upon which to base a decided opinion as to the existence of meningitis as a complication; for in some cases meningitis had been found after death, although he had not been able to distinguish the symptoms from those of ordinary delirium tremens during life.

Dr. Woodbury, in closing the discussion, said that the clinical phases of alcohol-poisoning offered an interesting and important topic for the practitioner, on account of the frequency of their occurrence and their usually urgent character. He had been surprised, upon reviewing the proceedings, that this subject had not within the last few years been brought up before the Society for discussion. On account of its comprehensive character he had only been able to sketch, and with rather a free hand, some of the rough outlines of the more prominent considerations springing out of the subject which he had submitted in the paper of the evening. In regard to the diagnosis of chronic meningitis he agreed with a previous speaker, that in simple cases occurring independently of alcoholism due attention to the symptoms would be sufficient to distinguish the case from ordinary delirium tremens. The previous history—of syphilis, sunstroke, blows upon the skull, or, rarely, rheumatism, with localized pain in the head of severe character, exacerbations of fever and delirium, with vomiting, but with onset less sudden than delirium tremens—may serve to distinguish such cases. When the conditions coexist, the use of the surface thermometer to the scalp would probably indicate the seat of the inflammatory process and aid in the diagnosis. If the patient complains of intense headache, and there is a decided febrile movement, frequent vomiting, and irregularly contracted pupils, the view of the coexistence of meningitis is tenable, and is at least highly probable. The fact that this complication is a frequent one has already been dwelt upon.

In concluding, he stated that although a man under the influence of a full dose of alcohol would generally succeed in sleeping off its effects, if kept warm, yet he felt that science—which shows alcohol to be a respiratory poison and capable of destroying life—protests against allowing a man in a condition of coma to sleep with an unknown amount of alcohol in his stomach waiting to be absorbed. When received into a hospital or station-house, such a patient should have his stomach emptied by an emetic or by the pump, and have a pint of hot coffee administered before allowing him to sleep; at the same time the skull should be carefully examined for injuries which may require prompt surgical attention.

PHILADELPHIA ACADEMY OF SURGERY.

STATED MEETING OF FEBRUARY 7, 1881.

DR. D. HAYES AGNEW, Vice-President, in the Chair.

ATROPHY OF MUSCLES AND BONES CONSECUTIVE TO CLUB-FOOT.

DR. T. G. MORTON presented two patients showing atrophy of the limbs from club-foot, in substantiation of his statement, made at a previous meeting, that the bones were diminished in acquired and congenital talipes, and that the affected leg never kept pace with the sound one.

D. C., aged 7 years, at the age of 20 months was suddenly seized with infantile palsy which involved the left lower extremity; he was in bed rather more than a week, and after this dragged the limb. In time it improved, and gradually he became able to use it freely. The limb has, however, never grown in the same proportion as the sound one. The child, as a result of this attack of palsy of the anterior leg muscles, has an acquired equinus, due to the unbalanced power of the calf muscles. Measurement shows differences in the circumference of the limbs and in the length of the bones. The left lower extremity is one inch shorter than the right, and one and a quarter inches less in girth below the knee. Around the point of the heel and the top of the foot the difference in measurement is a half-inch.

The second case was one of congenital club-foot with the following history. Six weeks

after birth he was operated on for equino-varus, and had subsequently a "sore foot," which prevented his wearing the apparatus prescribed. At six years of age a second operation was performed, which was also followed by a "sore foot." At the present time the bones of the left leg are smaller than those of the other; and careful measurement gives the following differences in the circumference of the limb at various points and in the length of the leg and foot:

The left is one inch less than the right at top of thigh; two and one-half inches less at middle of thigh; three and three-quarter inches less below knee; one and one-quarter inch less around heel; one and three-quarter inch less in length of foot; and one inch less in its entire length.

UPWARD DISLOCATION OF THE ACROMIAL END OF THE CLAVICLE.

Dr. S. W. Gross exhibited a gentleman suffering with this injury, caused by a fall, for whom he had had constructed an apparatus to prevent displacement of the joint-surfaces, which are retained in position with such difficulty after this dislocation. The elbow fitted into a sort of cup, from which a strap of webbing passed over the shoulder and by means of a pad made pressure upon the outer end of the clavicle. Other bands were required to prevent this primary one from slipping. The bone seemed to be in good position at the time of exhibition, which was five weeks after the accident. The apparatus was as efficient as strips of adhesive plaster, or the plaster-of-Paris bandage, and had advantages in regard to cleanliness and convenience.

Dr. Levis had thought of treating such cases, like fracture of the patella, by hooks or by wiring.

Dr. O. H. Allis stated that wiring had been done successfully by a surgeon in San Francisco.

SCROTAL TUMOR.

Dr. R. J. Levis brought to the notice of the Academy a patient having a large, painless, evidently non-malignant tumor of the right side of the scrotum. It had existed seven years, and was inconvenient only from its weight. On palpation it felt much like the mammary gland. Dr. Levis believed it to be a fibro-fatty growth, not connected with the cord or testicle, and probably outside of the vaginal tunic.

Dr. S. W. Gross believed it to be a fibro-fatty tumor of the spermatic cord, which had grown downwards. As far as his knowledge went, it was not likely to be an intrascrotal growth without being connected with the cord. Myomata, sarcomata, and fibromata are the forms of tumor that occur in the scrotum.

TRAUMATIC HERNIA OF THE BLADDER.

Dr. Morton presented a patient with traumatic hernia of the bladder, and read the following history of the case:

Jacob S., aged 34, single, was admitted into the Pennsylvania Hospital January 26, 1881. At the age of ten years he had sustained, by a machinery crush, a compound and comminuted fracture of the right pelvis, with dislocation and fracture of the head of the femur on the same side; the wound which communicated with the broken ilium extended from the anterior superior spinous process along the line of the groin and perineum, and involved the base of the bladder and outlet of the rectum; immense sloughing followed, from urinary infiltration, and subsequently erysipelas was developed. From the time of the accident up to 1868, fragments of bone continued to be thrown off, and the major portion of the pubis came away entire, as did also the head of the femur, split, however, in three pieces; consolidation of the shaft of the bone took place at an angle, on the dorsum ilii, with great shortening of the limb and immense atrophy; the wound in the groin and perineum closed up, except near the rectum, where a portion of the bladder protruded soon after the injury and has so continued to the present time, and from which opening all the urine is discharged, none having since the injury passed through the urethra; the outlet of the rectum in front is somewhat constricted by a band of tissue which extends across the perineum; but behind this bridge of skin the bladder and rectum open into each other.

The patient has since his recovery enjoyed the best of health, and is engaged in laborious work. An examination of the urethra shows it to be patulous to the neck of the bladder where the urethra is abruptly shut off, and at this place in the perineum the rupture of the bladder occurred. The patient is able to retain most of the urine, and does not suffer at all from incontinence, from the fact that the bladder falls forward and to the right side and fills up the space formerly occupied by the bony pelvis. He has no difficulty with the bowels unless when suffering from diarrhœa. He has ordinary venereal desire, but the discharges of semen pass through the vesical opening in the perineum. No operation was deemed advisable.

DEATH AFTER SOUNDING FOR VESICAL CALCULUS.

Dr. William Hunt showed a bladder and calculus removed from a man, aged 18 years, who had died at the Pennsylvania Hospital. The patient was admitted with symptoms of stone in the bladder, and was generally in a poor condition of health; he had never been sounded. The resident surgeon introduced a sound and discovered the calculus. On the day after the patient's admission, before Dr. Hunt had made his visit, death took place, without the occurrence of chill or fever, but apparently from profound nervous shock. The autopsy was partial, as permission could not be obtained to examine the kidneys or

chest. The patient, however, presented no œdema of the legs, nor had he had any convulsive seizures.

Dr. T. G. Morton thought it possible that the death had no connection with the examination of the bladder with the sound, but occurred from exhaustion due to prolonged suffering. He knew of an instance of death taking place after catheterization; but then chill and other symptoms of urethral fever had presented themselves.

JOHN B. ROBERTS, M.D.,
Recorder.

REVIEWS AND BOOK NOTICES.

A MANUAL OF DISEASES OF THE THROAT AND NOSE. By FRANCKE HUNTINGTON BOSWORTH, A.M., M.D., Lecturer on Diseases of the Throat in the Bellevue Hospital Medical College, and Physician-in-Charge of the Clinic for Diseases of the Throat in the Out-Door Department of Bellevue Hospital; Fellow of the New York Academy of Medicine, of the American Laryngological Association, and Member of the Medical Society of the County of New York. William Wood & Co., New York, 1881. 8vo, pp. xx, 427.

The rapid production of special works upon diseases of the throat and nasal passages, which have followed each other so closely during the past few months, is evidence of great attention to this special subject. The volume before us is from the pen of the Lecturer on Diseases of the Throat in Bellevue Hospital Medical College, New York, and is, as we glean from the preface, chiefly the outcome of an extensive personal experience. It treats of nearly all the affections which are apt to be brought to the notice of specialists in throat diseases. It is copiously illustrated, being particularly rich in pictures of instruments, supplied by an instrument-maker, to whose advertisement even several of the explanatory cuts in the use of instruments are made subservient. Of the illustrations of healthy and diseased structures a few are original, and these, as well as the remainder, have been selected with considerable care and judgment. The text is abundantly interspersed with working formulæ for treatment, mechanical and systemic; in addition to which there is an appendix of ten pages entirely devoted to the same subject. Although attention is prominently drawn to the author's individuality, we fail to perceive any preponderance of personal peculiarity in treatment, save in the condition of laryngeal phthisis. Even in the discussion of the treatment of bilateral paralysis of the abductors we have failed to read a line justifying the author's comment in his preface, that he has designedly treated of this and other subjects at considerable length "with the object of introducing personal views and methods of treatment which are not given in other works." We are of the opinion that all authors call prominent attention to the necessity of tracheotomy in the great majority of these cases.

Although the instructions for making laryngoscopic examinations are, as a rule, reliable and judicious, we are surprised to notice frequent inaccuracies of expression and uncorrected errors of reference, which detract very much from the value of the text. Thus, on the very first page, the laryngeal mirror is described in one sentence as attached to a slender wire stem, and in the very next sentence a stout stem is recommended. In the delineations of laryngoscopic mirrors we find two which are actually obsolete: one of them, probably, never having been used outside of Tübingen, where it originated. The author evidently prefers the naked gas-light and the simple reflector to all other methods of illumination. In commenting on the Tobold apparatus, he states that he has never been able to determine the optical principle upon which it has been employed; to learn which it would have been simply necessary to consult the formulæ printed in Tobold's own book. We are surprised, too, to see it asserted that it is usually taught that the laryngoscopic image in the mirror is reversed, when, in fact, all writers take especial care to teach the opposite. The average American student, we imagine, will be somewhat puzzled over the admirable enlarged view of the laryngoscopic image, without a line in text or description to anglicize the Latin terms imprinted in portions of the figure. On the same page, too, on this self-same very important subject of the laryngoscopic image, are a couple of incorrect references to illustrations,—an unfortunate oversight, the correction of which has been likewise overlooked in other portions of the volume. This is evidently the result simply of overcrowding with pictures accumulating at odd times, a circumstance accounting, probably, for a cut of something else instead of a powder-insufflator, and for a few similar inaccuracies that have caught our attention in running through the volume.

It would have been courteous to the memory of a much-abused man to have intimated that Dr. Green's skill in introducing the probang into the larynx and trachea had been demonstrated as well as "called in question." None should know better than the author that this procedure is practicable. Dr. Bosworth announces himself as a great advocate for the use of sprays instead of applications by brush and sponge. Although he has called in question the skill of a master in manipulating within the larynx without the aid of the laryngoscopic mirror, he dispenses with its aid himself in applying sprays to the larynx. Did he use the mirror he would see that in many instances his sprays do not get into the larynx at all. For accuracy of intralaryngeal

medication the mirror, in our opinion, should always be employed as a guide to the hand, except in those rare instances in which an unusually high and elevated epiglottis, visible on ordinary inspection of the throat, renders the use of the mirror superfluous. When the sprays do get into the larynx—unless the object is merely to flood the upper surface of the vocal cords during phonation—they are apt to go straight down the trachea, without touching the sides of the larynx at all, especially if propelled by the strong current of compressed air recommended in the text. On the other hand, a fragment of soft sponge introduced within the laryngeal cavity is brought in contact with its walls by the spasmodic action which it excites, and is thus a much more accurate means of application, and one that is much more limited in its action. Of course the larynx and trachea are not to be swabbed out as if the structure were a chimney-flue. But, with due care and skill, the sponge and even the brush are far more effectual chirurgical implements than the spray-producer, which has its uses, however, in the management of many affections of the throat and nasal passages.

The hygienic rules advocated by Dr. Bosworth are excellent and well intended, though the evils attributed to certain articles of apparel appear to us much too far-fetched.

The article on "taking cold" is a good one. Rather a curious line of argumentation, recalling our childhood's stories, is presented to favor the author's belief that a catarrh of the upper air-passages will lead to the eventual development of lung disorders,—a belief in which he differs from the majority of matured observers. Thus, he states, "there can be no question that an individual suffering from a chronic laryngeal catarrh is far more liable to an attack of tracheitis;" "one suffering from a tracheitis is far more susceptible to a bronchitis," "and so on down to the deeper lung-tissues." Why, few observations are more general than that the bronchitis of the aged existed for years without ever impairing the deeper structures; and surely the author's experience must have shown him many a case of confirmed laryngo-tracheitis of long standing without any history of intercurrent bronchitis.

To turn now to the descriptions of diseases and their remedies. Descriptions of diseases are sufficiently minute, without being prolix. The chief points of pathological interest are fairly indicated, and hypothetic speculation is avoided. The therapeutic resources are more minutely laid down than has been the case in the majority of works published upon the same subjects, the choice of a number of formulæ being presented in connection with nearly every therapeutic commendation. The author's views on laryngeal phthisis are peculiar, and he claims much greater success in its treatment than other authors, even to the habitual cicatrization of the phthisical ulcerations. As this subject has been fully presented in the medical journals, we need not go into details here, but merely state that the chief peculiarity of the author's local treatment consists in thorough cleansing of the parts, followed by the application in succession of astringents, anodynes, and iodoform. His success is certainly exceptional.

In connection with the subject of syphilis, the author has, in two instances, recognized the mucous patch upon the ventricular bands. These are stated to be the only cases in which he has felt convinced of the presence of the mucous patch in the larynx. A combination of local cauterization by the fused nitrate of silver, followed by the application of iodoform to the cauterized surface, has proved more effective in the author's hands in the management of these patches than any other remedial resource. He acknowledges the importance of the internal administration of mercury, thereby coinciding with the majority of writers on the subject, in contrast to the almost isolated position of Mackenzie. We find frequent evidence of endorsement of the value of the local action of morphia in obtunding the pain of ulcerative conditions of the larynx from whatever cause.

The author appears to find less difficulty in distinguishing the ulcers produced by syphilitic, tuberculous, or carcinomatous influence, and presents a table detailing their distinguishing characteristics. There is a well-illustrated description of the methods of overcoming cicatricial stenosis of the larynx, and a fair exposition of the subject of extirpation of the larynx. The latter contains a larger collation of cases than has been previously published. Unfortunately, no references are given to the original reports. And in fact, except in connection with the subject of bilateral paralysis of the abductors of the larynx, we have failed to come across a single reference. In conclusion, while conceding the value of this volume as an expression of the author's opinions and practice, we must acknowledge that it is both too meagre for a treatise and too extensive for a manual. A good manual or working volume on diseases of the throat and nasal passages, adapted to the requirements of the young or inexperienced physician, has yet to be written. J. S. C.

A Practical Treatise on Surgical Diagnosis. Designed as a Manual for Practitioners and Students. By Ambrose L. Ranney, A.M., M.D., Adjunct Professor of Anatomy, and late Lecturer on the Surgical Diseases of the Genito-Urinary Organs and on Minor Surgery, in the Medical Department of the University of the City of New York, etc., etc. New York, William Wood & Co. Second Edition, pp. 471.

The author has, as we conceive, undertaken a task such as no man can satisfactorily carry

out in the way he has mapped out for himself. We regret that there seems to be such a demand for works like the present, as is shown by the issue of this second edition of Dr. Ranney's book. This work is too much like the "royal roads to knowledge" which are so much in vogue nowadays, and which in most instances the readers find to be "royal roads to error,"—or, in other words, they will discover that no one can successfully arrive at a correct diagnosis by reading over a table of diagnostic points disassociated from the etiology, pathology, and history of the disease. We are opposed to works like the present, believing them to be pernicious in their tendency. The only way to write a useful work on surgical diagnosis is to write a concise text-book on the science of surgery, omitting merely prognosis. A work like Da Costa's in surgery *might* be useful, although we think that any good surgical text-book is all a student or practitioner needs; but one like the present, where a differential diagnosis is to be founded on such distinctions as "sometimes," "usually," "often," "if," etc., can scarcely be satisfactory. Let no one imagine that we do not know the impossibility of not using such terms as the above; but they should, and can, have appended to them the reasons for such exceptions, or why one symptom is "sometimes" present in one case, while in another apparently identical one it is absent. In fine, to render such a complicated subject as surgical diagnosis clear, a certain amount of knowledge of the etiology, pathology, etc., of the disease is essential. This information cannot be incorporated in a table, and for that reason we think the plan a mistake. Having thus far pursued the ungrateful task of condemnation, let us see wherein the work is worthy of praise. In the first place, its author must have appreciated the force of what we have just said, since we understand that much more explanatory text has been introduced in this edition at the opening of each chapter. In so far as this goes it is good. What is given in the text, we confess, in the main is satisfactory, although where pathology is mentioned the views are not always thoroughly orthodox.

The style, too, is quite up to the average. The diagnostic points in the various tables are excellent, and do the author credit. In fine, while we cannot think that the work can possibly be a thoroughly good book for students, it may prove of use to the busy practitioner as a refresher of his memory. The practitioner can mentally supply the missing links which the salient points will serve to recall, but the student who is without that prerequisite information will be only too apt to be satisfied with this royal access to knowledge, which must prove but a broken reed in time of trouble. Used as we have just indicated, and by graduates, we would qualifiedly recommend it, although we reiterate our former statement that a good text-book is a better one to read when in doubt about any case. To the student we would say, Remember the old adage, "The longest way around is the shortest way home."

C. B. N.

A Guide to the Examination of the Urine. Designed chiefly for the Use of Clinical Clerks and Students. By J. Wickham Legg, M.D. Fifth Edition. Philadelphia, Presley Blakiston, 1880. 16mo, pp. 110.

Hand-Book of Systematic Urinary Analysis, Chemical and Microscopical. For the Use of Physicians, Medical Students, and Clinical Assistants. By Frank M. Deems, M.D. New York, Industrial Publication Company, 1880. 16mo, pp. 30.

How a Person threatened or affected with Bright's Disease ought to Live. By Joseph Edwards, M.D. Philadelphia, Presley Blakiston, 1880. 16mo, pp. 87.

Dr. Legg's little book, having reached the fifth edition, is too well known to require any extended notice. The present edition has been carefully revised.

The hand-book of Dr. Deems is really a convenient collection of tables arranged in sections, in which are succinctly given the principal facts as to the general physical characters of the urine and directions for testing for its normal and abnormal constituents. All essential directions seem to be included, and among them are some practical hints we have not seen elsewhere. Among these are the directions for decolorizing urine before testing for sugar, according to which a tablespoonful of animal charcoal and a pinch of sodium carbonate are added to two ounces of urine in a bottle, the mixture shaken for five or ten minutes, and filtered. Again, "Hold the urinometer-cylinder obliquely, when filling it, to avoid a foam," obviates a troublesome occurrence by which time is often lost. The little contrivance the object of which is to serve at the same time as a urinometer-glass and a collector of sediment is the best yet suggested, but, as the measures described to secure cleanliness are absolutely essential, we question whether there is much economy of time in its use as compared with that of the usual conical glasses and pipettes. We would suggest that those, at least, who make many examinations should have a couple of the modified burettes and stand, as well as extra pieces of gum tubing and attached glass jets. In this manner a clean one could be always at hand.

The little book has the advantage of being inexpensive as well as reliable.

The third book on the list, by Dr. Edwards, "How a Person affected with Bright's Disease ought to Live," is not written for the professional reader, but might be read by him with advantage, containing, as it does, many valu-

able suggestions, although we cannot agree with the writer in all his recommendations,—as, for example, the total proscription of alcohol and diuretics. We do not think alcohol has directly caused many cases of Bright's disease, and in moderate quantity freely diluted it cannot do any direct harm as long as the liver and lungs remain as a bulwark between the stomach and kidneys. It is true that the free consumption of alcohol, by producing gastritis and interfering with digestion, prevents proper assimilation, and thus indirectly affects the kidneys unfavorably, and if very large amounts are ingested, some will pass through the liver and lungs unoxidized and irritate the kidneys. Not so with moderate quantities freely diluted. Again, with regard to diuretics. While stimulating diuretics are harmful, such as act by increasing blood-pressure from behind, as digitalis, diluents, and the vegetable alkalies, are harmless, and often necessary to remove the dropsy which is so frequent a symptom. J. T.

GLEANINGS FROM EXCHANGES.

Backache—its Causes.—Dr. George Johnson (*Brit. Med. Jour.*, vol. i., 1881, p. 221) says that in the great majority of cases the pain of backache has its seat in the muscles, and is a simple result of strain or over-fatigue of the lumbar and erectores spinæ muscles and tendons. A remarkable feature of the pain resulting from excessive muscular exercise is that, while it may continue more or less during rest in bed, it is usually much increased by the first movements after rest, but gradually diminishes after moderate exercise. In muscular lumbago, standing is more fatiguing for the back and legs than walking, and leaning forward puts a greater strain on the muscles of the back than standing erect. Pain is often more severe on one side than on the other, owing to the common practice of throwing the weight more on one leg than on the other. A common cause of painful overstrain in the dorsal muscles is an excessive weight in the abdomen, whether from advanced pregnancy, dropsy, or excessive development of fat. Dr. Johnson, in speaking of these causes, incidentally gives the dietary advisable in obesity. He also calls attention to dyspeptic myalgia resulting from malnutrition of the muscle. "Growing-pains," Dr. Johnson thinks, are due to excessive muscular exercise, and are to be cured by rest. Sudden pain is sometimes caused by cramp or rupture of some fibres of the muscle during contraction. Indigestible foods sometimes cause cramps in muscles in certain individuals instead of cramps in the stomach. Cold, as is well known, is a frequent cause of pains in other muscles besides those of the back. For lumbago Dr. Johnson recommends hot air or Turkish baths, followed by vigorous shampooing; also an embrocation composed of equal parts of linimentum belladonnæ and linimentum opii.

Other causes of backache are aneurism of the aorta, the symptoms of which Dr. Johnson gives at some length, with illustrative cases; cancerous glands in the abdomen; diseases of the kidneys; gastric ulcer; uterine diseases; diseases of the bones of the spine and of the spinal cord; and, finally, the backache of commencing fevers.

New Facts regarding the Use of the Bromides in Epilepsy.—Dr. A. Hughes Bennett (*Edin. Med. Jour.*, February, 1881, p. 706) says that the general circumstances of the individual are to be studied; his diet, hygiene, surroundings, habits, etc., if faulty, are, when practicable, to be improved. The bromides, when ordered, are to be taken without intermission. The minimum quantity for an adult to begin with is thirty grains three times a day,—the first dose half an hour before rising in the morning, the second in the middle of the day, on an empty stomach, and the third at bedtime. This is continued for a fortnight, and, if with success, is persevered with, according to circumstances, for a period varying from two to six months. If, on the other hand, the attacks are not materially diminished in frequency, the dose is immediately increased by ten grains at a time until the paroxysms are arrested. In this way as much as sixty to eighty grains thrice daily have been administered by Dr. Bennett, and, with one or two isolated exceptions, he has never found a case which resisted the treatment. He has never seen any really serious symptoms of poisoning or injury to the general health. Sometimes these amounts must be continued, but oftener it is better to diminish to that dose which will keep the attacks in check without seriously interfering with the patient's health. His experience with three hundred cases (of which he gives tables) has been so favorable as to lead him to believe epilepsy, of all chronic nervous diseases, is the one most amenable to treatment. Dr. Bennett's favorite prescription is as follows:

℞ Potass. bromid.,
Ammon. bromid., āā gr. xv;
Sp. ammon. aromat., f℥ss;
Infus. quassiæ ad f℥i.—M.
Sig.—Thrice daily.

Headaches of Childhood.—Dr. William Lee read a paper on this subject before the Clinical Society of Maryland (*N. Y. Med. Rec.*, vol. i., 1881, p. 303), in which he said that headache among school-children is apt to be hereditary, and is especially to be traced to confinement and over-study at a time of life when the brain is still undeveloped. Its causes are (1) overtaxing the brain; (2) gastric and intestinal disturbance, worms; (3) anæmia (from malaria, etc.), producing neu-

ralgia or nervous headache. Monobromide of camphor, he thought, gave the best results in the first class of cases. In sick-headache, the second variety, fluid extract of guarana (especially if the patient be kept at rest after using,—a very important precaution) and nux vomica are the most efficient remedies; the latter is a most important remedy. The third variety may be due to teething. A general tonic plan, including valerianate of zinc, may be used here. In malarial headaches, Fowler's solution and dialyzed iron give the best results. In the discussion following the reading of the paper, attention was drawn to the fact that optical headaches had been omitted, also headaches from defective ventilation.

THE CROTON-OIL TREATMENT IN RINGWORM.—The croton-oil treatment, as it is called, which has recently been brought prominently to the notice of the profession by Dr. Alder Smith, is one with which every practitioner who may have charge of an institution where numbers of children are brought together should be familiar. It appears to be the best method of extirpating ringworm of the scalp in institutions yet devised. Dr. Liveing (*Brit. Med. Jour.*, vol. i., 1881, p. 227) calls further attention to this method of treatment, and says that those who wish to use croton oil with safety and success should adopt the following rules, which are, perhaps, a little on the side of caution. 1. Not to use it for children under ten years of age. 2. Never to apply it at any one time to a surface larger than a florin. 3. To use it only in chronic cases which will not yield to ordinary treatment. 4. To use it only with the consent of the patient's friends, the nature of the treatment and the effect of the croton oil on the skin being first fully explained. If the last rule be not carried out, parents are apt to think their children are being over-treated.

SUPPURATION OF ENLARGED THYROID.—Spontaneous suppuration of a goitre, says the *Lancet*, is one of the least common terminations. An instance in which this occurred during the course of an attack of typhoid fever, in a case under Dr. Jaccoud's care, is recorded by Weill. The patient, a man of 22, had a goitre of moderate size and firm consistence. He had lived until within four months in a district where goitre is endemic. The attack of typhoid fever ran a normal and mild course. The day after the temperature had become natural he complained of severe pain in the neck, and the surface of the goitre was observed to be reddened. During the next day the redness and size of the goitre increased, and its consistence diminished until distinct fluctuation was perceptible. A week later it was incised, and a large quantity of pus escaped. A drainage-tube was applied, and the cavity was washed out daily with carbolic acid. It gradually lessened in size, and was ultimately reduced to two or three small nodules by the side of the larynx.

THE PHARMACOLOGY OF CHLORAL HYDRATE.—M. Dmitrieff states that he has tested the effect of chloral hydrate, both clinically and experimentally, on unhealthy, badly-granulating wounds. By excision of a piece of skin in dogs and infection of the wound with putrefying matter, he produced unhealthy ulcerating surfaces. Some of these he dressed with one or two per cent. solution of chloral hydrate, while the rest were simply covered with a moist cloth. The first very soon became healthy, and cicatrized before the others. The ulcers, on microscopic examination, were found covered with a layer of micrococci, which disappeared after two or three days' dressing with chloral hydrate. These results were confirmed clinically; and the writer has also shown that an equal quantity of a one per cent. solution of chloral hydrate destroyed in twenty minutes all mobility of the bacteria in a putrefying infusion of flesh. —*Brit. Med. Jour.*, vol. i., 1881, p. 48.

CHILBLAINS.—A correspondent of the *British Medical Journal* having written to inquire as to the best treatment of this ailment, he is advised by one writer in reply to use cold bathing, loose boots with thick stockings, and applications of nitrate of silver if the surface is unbroken. Another writer suggests sponging with the negative pole of a galvanic battery, the current being as strong as can be borne. Another recommends liniment of aconite. Other recommendations are: an ointment of lard and dry mustard rubbed in before a fire for twenty minutes at night; painting with flexible collodion; sponging with very hot water; strong solution of acetate of lead; sulphurous acid; and, finally, the following: curd soap, ℥i; water, ℥iv; dissolve with heat, and add gum camphor, ʒiv; rectified spirits, ʒvi; essence of bergamot, ℈ij; liq. ammoniæ fort., ʒvi. Make into a liniment to be rubbed in.

CERTAIN PHYSIOLOGICAL EFFECTS OF STRETCHING THE SCIATIC NERVE. — Prof. Brown-Séquard (*Lancet*, vol. i., 1881, p. 206) has made some experiments on nerve-stretching in guinea-pigs. It is known that, in these animals, transversal hemisection of the dorsal spinal cord is followed by decided hyperæsthesia, with considerable paralysis, in the posterior limb on the corresponding side, while there is a marked degree of anæsthesia (and even sometimes a complete loss of feeling) in the posterior limb on the side opposite to that of the lesion. Rabbits are about the same, while in dogs the hyperæsthesia and anæsthesia are not so well marked. In Dr. Brown-Séquard's experiments eleven guinea-pigs were thus operated upon; the upper part of the sciatic nerve of the operated side was then stretched. In eight of the animals considerable return of sensibility in the limb operated upon occurred within a short time. In three

animals no change took place, but in two of these more than half of the cord had been cut. Hyperæsthesia took the place of anæsthesia in some of the eight animals, and even the hyperæsthesia of the opposite limb increased.

The experiments on rabbits did not give clear results. One dog experimented upon showed not only return of sensibility and hyperæsthesia on the side of the stretched nerve, but increase of hyperæsthesia on the other side as well, with loss of voluntary motion on both sides. Dr. Brown-Séquard thinks the cord itself is affected, and draws conclusions from these experiments unfavorable to the operation of nerve-stretching in locomotor ataxy.

INGLUVIN.—Dr. Dabbs (*British Medical Journal*, vol. i., 1881, p. 86) does not find it best to give ingluvin before meals in dyspepsia, the vomiting of pregnancy, etc., nor is it necessary to give it thrice daily. He gives ten grains in water as early as possible in the morning, say 5 or 6 A.M. At 8 or 9 A.M. fifteen grains more are given, and an hour after this second dose a breakfast of iced soda-water and milk with dry toast is taken. On the second morning fifteen grains are given very early, and twenty grains later (before food is taken); on the third day twenty grains are given at each dose, and by this time the vomiting has probably ceased, and the ingluvin may be taken thrice daily in ten-grain doses. In the atonic dyspepsia of early phthisis Dr. Dabbs considers ingluvin particularly valuable.

TOLERATION OF OPIUM IN THE INFANT.—Dr. J. Mackenzie Booth writes to the *British Medical Journal*, November 13, 1880, describing the case of an infant to whom opium was given for colic in increasing doses until, at the age of four months, the infant was getting, in drachm doses, from six to eight drachms of laudanum in the twenty-four hours. On coming under Dr. Booth's care, he was extremely emaciated, but gradually recovered on taking away the opium by degrees and giving nourishing food and cod-liver oil.

GRANULAR PHARYNGITIS.—The anatomical characters of so-called "granular pharyngitis" have been made the subject of investigation by Dr. Saalfeld, of Stettin (*Virchow's Archiv; Med. Times and Gaz.*, 1880, p. 570). Dr. Saalfeld finds that the essential pathological changes in this form of sore throat consist in an increase of the lymphatic tissue of the mucous membrane around the duct of an hypertrophied mucous gland, that portion of the duct being dilated which lies in the thickened tissue.

KELOID OF THE EXTREMITY OF THE EAR.—Dr. Axel Key (*Hygieia; British Medical Journal*, vol. ii., 1880, p. 808) gives a case where keloid growths had arisen from the scars of perforations made for the purpose of introducing ear-rings. Eight times in twenty years these growths had been extirpated and had returned. When last taken away, the tumor had one and a few tenths inches in breadth and a little more than one and a half inches in length. It projected in a round form from above the surrounding skin, from which it was sharply defined. It was everywhere hard, firm, and elastic, and presented, on section, the appearance of firm connective tissue, with a gray-white surface traversed by a net-work of whitish fibres.

A NEW REMEDY IN PRURITUS.—Dr. L. D. Bulkley (*New York Med. Jour.*, 1881, p. 30) uses gelseminum. Beginning with ten drops of the tincture, if in half an hour the itching is not relieved, and there are no toxic symptoms, as languor, the remedy is repeated in the dose of twelve or fifteen drops, and so on until results are obtained, or until a drachm or so has been taken in two hours. He has never pushed it to any of the severer symptoms, and has often found relief after the first dose.

REMEDIES FOR CHILBLAINS.—The following formula for Dr. Valentine Mott's remedy is given in the Proceedings of the Medical Society of the County of Kings:

℞ Beef's gall, ℥iv;
Ol. terebinth., ℥iv;
Spt. vini rect., 90 per cent., ℥iss;
Tinct. opii, ℥i.

Another formula for the same affection is,—

℞ Beef brine, Oj;
Potassæ nitratis, ℥ij;
Aquæ ammoniæ, ℥iij.

CORRIGAN'S BUTTON IN RESTORING THE HEART'S ACTION.—Dr. Mullin writes to the *British Medical Journal* urging the use of the simple and efficient instrument known as Corrigan's button. He does not describe this instrument, but says that an ordinary metal spoon or iron key, warmed in the flame of a candle or gas-jet, might be used. It should be heated till the finger can just bear it, and then used to give a few short, sharp taps over the region of the heart. Two incentives to arouse the action of the heart are thus given,—the effects of the tapping itself and the shock of quickly-applied heat,—more potent, perhaps, than electricity.

ASTHMA TREATED BY LOCAL APPLICATION OF IODINE.—A correspondent of the *British Medical Journal* had a very severe and chronic case of asthma under his care, for the relief of which he painted over the line of both pneumogastric nerves with iodine liniment,—full strength. This proving too strong, an application of half strength was substituted for it and applied for the next two days, at night, and subsequently less frequently. The patient's condition improved greatly. No medicine was used internally.

ASSOCIATION OF TONSILLITIS AND RHEUMATISM.—A correspondent of the *Lancet* calls attention to the fact, sometimes forgotten, that in certain members of arthritic families tonsillitis occasionally appears to take the place

of the articular affection. He has sometimes endeavored to treat tonsillitis by the abortive process, with the result of laying up his patient with subacute rheumatism. Under these circumstances he believes Dr. Liveing's suggestion of giving colchicum a good trial in recurrent quinsy to be a good one.

SCLERODERMA INFANTUM.—Under this name a correspondent of the *British Medical Journal* (vol. i., 1881, p. 192) describes the case of a newly-born seven months' child whose skin was hard, leathery, and tense (so much so that the legs could not be straightened), and on no part of the body could the skin be pinched up. With artificial respiration it was brought to give one or two faint gasps, but then died. No post-mortem examination was made.

IODINE A SUBSTITUTE FOR QUINIA.—Dr. Grinnell says (*Canada Medical and Surgical Journal*, 1880) that, given boldly,—*i.e.*, in doses of ten to twelve drops of the tincture in half a glass of sweetened water every eight hours,—iodine will never rank second to quinia in the treatment of intermittent fevers.

KAVA-KAVA is an efficient remedy in purulent inflammations of the urinary tract and in cystitis. In urethritis the following formula may be employed: sixty grammes of the fluid extract of kava-kava, two grammes of benzoic acid, and twelve grammes of powdered borax. Three teaspoonfuls daily.

QUEBRACHO has been used by J. R. Berkart as an efficient palliative in the dyspnœa of emphysema, atheroma, and fatty degeneration of the heart. Relief followed within three minutes after the exhibition of a teaspoonful of the fluid extract.—*Lancet*, vol. i., 1881, p. 75.

HOT-WATER COMPRESSES IN TETANUS AND TRISMUS.—Spoerer dips a large-enough piece of coarse flannel in water of a temperature which can just be borne by the hand, and applies the compress to the occiput and along the spine.—*Lancet*, vol. i., 1881, p. 75.

BLACK URINE IN ACUTE POISONING FROM CHLORATE OF POTASSIUM.—At a recent meeting of the Society of German Physicians (*New York Medical Record*, 1881, p. 23) Dr. Jacobi showed a sample of characteristically black urine voided by a patient who had been poisoned by overdoses of chlorate of potassium.

SYPHILITIC ELEPHANTIASIS.—At the same meeting Dr. Klotz showed a specimen of syphilitic elephantiasis of the leg, which he had exhibited at a previous meeting of the Society. The extensive necroses of the soft coverings of the leg were ascribed to the existence of an arteriitis obliterans. Last October the patient began to complain of rheumatoid pains in the hitherto unaffected leg of the left side. This was rapidly followed by extensive gangrene of the soft parts, showing that here also the vascular affection previously diagnosed had occurred. The patient was now gradually sinking into symptoms of slow septicæmia.

MISCELLANY.

IMPROVED COLD CREAM.—A correspondent of the *Chemist and Druggist* offers the following receipt:

"This formula for cold cream I have never published before, and I think it is really good in every way: at any rate, it meets with unsolicited encomiums from purchasers, and it gives myself more satisfaction than any I have tried. I have used it some years:

"℞ Cera alba, ℥ix;
Cetaceum, ℥ix;
Ol. amygdal., ℥xii;
Aqua, ℥vii;
Creta præcip., ℥i;
Otto rosæ, *ad lib.*;
Chloroform, gtt. xii.

"Put cera, cetaceum, aqua, creta præcip., together with half of the ol. amygd., melt in an earthenware vessel by water heat, stir in the other half of ol. amygd., and continue till cold. The more stirring, the better the result. Add otto and chloroform when cold."

[The addition of precipitated chalk and chloroform has the probable effect of preventing the preparation from becoming rancid. The chalk, through its saturating properties, neutralizes the acids, which by their presence are known to promote the peculiar fermentation causing the rancidity of fatty substances. The chloroform, owing to its antiseptic action, prevents the propagation of destructive germs. Both are unobjectionable for cosmetic purposes; but the carbonate of lime is not allowable in cold cream to be used medicinally.]—*Druggists' Circular.*

LONGEVITY IN THE "GOOD OLD TIMES."—There is one point which is too frequently overlooked by writers on historical cases of longevity,—the singular difference between our estimation of an old man and that of our forefathers. "Old John of Gaunt, time-honored Lancaster," died at 59; so did James I.; Henry VIII. only reached 53. The Huguenot admiral Coligny, whose "hoary hair, all dabbled o'er with blood," is mentioned by Macaulay, and whom his earlier biographer, Lord Huntington, represents as a very old man, was slain at 53, when, in these days of Moltkes, Gortschakoffs, Gladstones, Beaconsfields, Dufaures, Broughams, and Lyndhursts, a man is supposed to be rather on the juvenile side. In point of fact, for our ancestors a man of 50 was old; with us the limit is nearer 80. It is legitimately to be inferred from this fact, in the first place, that the average duration of human life was shorter in past time than it is nowadays; in the second, that the chances of error in accounts of alleged centenarians were infinitely greater,—that if a man of 80 or 85 called himself 100 or 110 his story would be exceedingly apt to be believed.—*The American.*

MIDWIFERY IN THE PARIS HOSPITALS.—The *British Medical Journal* says that lately

some scandalous facts have come to light relative to the working of the obstetrical department of the Paris hospitals. Pregnant women are usually admitted into the general wards, and attended by the physician or surgeon of the ward. No precaution is taken to guard the lying-in woman from infection: she may have lying on one side a patient dying of pyæmia, and on the other a case of diphtheria or scarlatina. The mortality is beyond anything reached elsewhere: it is a wonder any women escape with their lives. To entice women into hospitals, where they expect all the resources of medical science to be at their aid, and to give them treatment compared with which that of the most ignorant midwife would be immeasurably superior, is, indeed, a disgrace to civilization and to Paris. "We hope, for the sake of humanity," concludes the *Journal*, "that the municipal council of Paris will boldly and effectively wipe out this blood-stain of murdered women and children. In no other city in the world could such things happen."

CITRIC ACID TO RENDER WATER SAFELY POTABLE.—Dr. Langfeldt has experimented with a number of substances in studying their applicability to the purpose of destroying microscopic life in drinking-water. The most striking results he obtained from citric acid. Upon the addition of one part to two thousand, life ceased in from one-half to two minutes. Microscopic examination showed that those forms of animalcula supplied with a thick epithelial covering are not affected by this dilute citric acid, but only those with delicate coatings. But as the greater portion of these unwelcome visitors belong to the latter category, and as those of the former variety are visible to the naked eye, a solution of the above-mentioned strength (1 to 2000) will suffice as a safeguard. In about one minute after their death these animalcula settle to the bottom of the vessel containing the water, and can always be found in abundance in the sediment. As the solution of citric acid spoils so readily, Langfeldt advises that it should be freshly prepared every day. —*Druggists' Circular.*

WHALES were formerly counted as important aids to the fisheries of the North Sea coasts, by driving immense numbers of small fishes towards the land. Now, according to M. Bogdanoff, of the recent Russian North Sea expedition, since the whales have been pursued with steamers and bullets instead of sailing-vessels and the old harpoon, their destruction has greatly increased, and the number of small fishes coming to the coast has correspondingly diminished. The cod-fishing has been nearly extinguished in parts of the Varanger Fiord region in consequence of the presence of sharks, which, attracted by the fat thrown into the sea at Varanger, destroy the fish. Both of these instances illustrate the interdependence which exists among the different kinds of animals inhabiting the same region.

FOREIGN BODY IN THE INTESTINE.—A correspondent of the *Lancet* gives the case of a boy of 10 who accidentally swallowed a pin. He forgot all about the circumstance, and continued in good health during the subsequent four months. At the end of that time he came under treatment for slight tenesmus and pain on defecation,—symptoms which were relieved by a dose of castor oil. Four days later he thought he felt a bone in the lower bowel, and an examination then revealed a sharp-pointed black pin about one and one-quarter inches long, which had passed through the rectum and was piercing the skin half an inch to the right of the anus. Two days after the removal of the pin the parts were healed and the lad was well.

THE Thirty-Second Annual Meeting of the Pennsylvania State Medical Society will be held in the city of Lancaster on Wednesday, Thursday, and Friday, May 11, 12, and 13, 1881, commencing on Wednesday at 9 A.M.

OBITUARY. — Dr. Isaac Ray, the distinguished alienist, died, at his residence in this city, on Thursday, March 31, in the seventy-fourth year of his age.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM MARCH 20 TO APRIL 2, 1881.

GIBSON, J. R., MAJOR AND SURGEON.—Relieved from duty at Fort McHenry, Md., and to report to the Commanding Officer, United States Barracks, Washington, D.C., for duty as Post-Surgeon. S. O. 52, Department of the East, March 22, 1881.

BROWN, H. E., MAJOR AND SURGEON. — Promoted from Assistant-Surgeon, vice Otis, deceased.

MEACHAM, F., CAPTAIN AND ASSISTANT-SURGEON. — To report for duty to the Commanding Officer, Fort Hamilton, New York Harbor. S. O. 52, c. s., Department of the East.

WOODRUFF, E., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty in Department of Texas, to proceed to New York City, and, by letter, report arrival to the Surgeon-General. S. O. 72, A. G. O., March 30, 1881.

AINSWORTH, F. C., CAPTAIN AND ASSISTANT-SURGEON (now awaiting orders in New York City).—To report in person to the Commanding General, Department of Texas, for assignment to duty.—S. O. 72, c. s., A. G. O.

WORTHINGTON, J. C., CAPTAIN AND ASSISTANT-SURGEON (now on leave of absence).—To report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 72, c. s., A. G. O.

REED, W., CAPTAIN AND ASSISTANT-SURGEON (awaiting orders at Fort McHenry, Md.).—To report to the Commanding Officer of that post for duty. S. O. 52, c. s, Department of the East.

PORTER, J. Y., CAPTAIN AND ASSISTANT-SURGEON. — Granted leave of absence for one month, to take effect from 6th proximo. S. O. 28, Department of the South, March 22, 1881.

SCHUÉ, E. D., FIRST-LIEUTENANT AND ASSISTANT-SURGEON. —When relieved at Fort Grant by Assistant-Surgeon J. B. Girard, to report in person to the Commanding Officer, Camp Thomas, A.T., for duty. S. O. 27, Department of Arizona, March 8, 1881.

KING, J. H. T., CAPTAIN AND ASSISTANT-SURGEON.—The leave of absence granted him in S. O. 253, November 29, 1880, from A. G. O., is extended to June 30, 1881, and his resignation accepted by the President of the United States, to take effect June 30, 1881. S. O. 65, A. G. O., March 21, 1881.

PHILADELPHIA MEDICAL TIMES.

PHILADELPHIA, APRIL 23, 1881.

ORIGINAL COMMUNICATIONS.

THE TREATMENT OF EXOPHTHALMIC GOITRE BY ELECTRICITY.

BY WILLIAM R. D. BLACKWOOD, M.D.,
Physician to St. Mary's Hospital.

TO those skilled in the treatment of obscure nervous disorders, it may seem an unwarranted assertion that Graves' disease is a malady unwelcome to the general practitioner, as being one not easy to treat, and one which therefore does not reflect favorably on his skill; and in this I do not mean to say that the problems in disease encountered by the family practitioner are, as a rule, easy, and that his burden is, per consequence, light; nor do I imply, on the other hand, that it is either necessary or desirable that difficult cases of any kind should be in general turned over to the specialist. On the contrary, two of the cases narrated herein were, at one time during their progress, under the care of well-known neurologists, whose success was not better in the end than that of the gentlemen from whose practice the patients originally came. In many standard works, however, the prognosis of this distressing form of goitre is set down as very favorable; yet the identical treatment recommended by the authors has over and over again failed to either cure or to afford decided relief in the hands of others; and such a state of affairs is by no means encouraging,—to the young practitioner particularly. The action of every drug in the Pharmacopœia is well known to be influenced by the idiosyncrasy of the patient at times, just as in food, where, according to an old saying, "one man's meat is another man's poison," and the occasional failure to secure prompt or radical amendment in the variety of goitre under consideration may of course be due largely to this fact. At any rate, the cases herein reported went from bad to worse, under excellent management, until electrical measures were instituted; and as the profession at large is by no means agreed on the value of this therapeutic agent, they are presented with a view to encourage further investigation in a field which is wide enough to afford more definite conclusions than have heretofore been had.

E. M. H. menstruated for the first time in her fourteenth year, and enjoyed, as she did before that event, perfect health until the next year, when, from supposed overexertion at a picnic, she complained of cardiac palpitation on slight exertion, carotid throbbing on assuming the horizontal posture at night, within some six months thereafter increasing dyspnœa, and within a year from seizure perceptible thyroid enlargement. Treatment was instituted shortly after her first complaining, digitalis, aconite, and belladonna being employed. Her general health precluded iron and other tonics, but, exophthalmos becoming evident about a year after first complaining, she was put upon iron and arsenic. Her functions were all in perfect accord, yet her goitre steadily increased despite treatment. She tried Saratoga and other spas without benefit, and then went under the care of a specialist, in whose hands a cure was virtually guaranteed. Ergot internally and hypodermically into the tumor, bromine and iodine, cannabis Indica and veratrum, all failed to afford relief, and, her dyspnœa having at the end of the third year become almost unbearable, additional advice was procured. I have been unable to secure a history of what measures were adopted after this time, but the failure to do so is unimportant, as matters were in no way improved. Through a relative whose family I attend, she casually introduced the subject to me, and, her usual attendant and the consultant first called in willingly resigning the case, and she declining further attention from the second, I took charge of what had in the past at any rate been certainly an unpromising problem. With drugs faithfully tried, almost nothing had been accomplished: their best service had been merely temporary. All medicinal measures were at once abandoned. Beyond some dyspeptic symptoms, due doubtless to heroic bromide prescriptions, and the natural depression of spirit at what seemed a lingering death, she was in other respects in better health than might be expected in one whose life was, as she described it, a burden. She had at times a tendency to menorrhagia; otherwise her menstrual phenomena were normal. Her pulse varied from 120 to 155. There was hypertrophy, though not excessively so, of the heart, but no pronounced valvular le-

sion. The eyeballs were decidedly prominent, the lids barely covering them whilst the patient was asleep. The neck measured seventeen and a quarter inches round,—an increase of how much not then known. To test the relative value of galvanic and induction currents, she was faradized daily for a week, without any benefit either apparent or felt. The current was applied to the cervical sympathetic, and centrally to the solar plexus. Then galvanism was instituted, the applications being made in a similar manner,—first to the sympathetic, one pole being placed centrally at the base of the brain, and the other on the anterior border of the sterno-mastoid, it being moved from the auriculo-maxillary space down to the clavicle, and up again first on one side and then on the other. After the first week, central galvanization was added, one pole over the solar plexus, the other traversing the spinal column. The duration of the applications varied from five minutes at first to half an hour at farthest, the strength of current being regulated according to circumstances, usually from ten to fifteen cells comprising the circuit. More than twenty elements provoked giddiness at any time. After the second week amelioration of her dyspnœa and circulatory disturbance was acknowledged voluntarily, and in four weeks the neck was one inch less in circumference; in six weeks the ocular protrusion was notably lessened, the night was comfortably spent invariably, the leaning towards excessive menstrual flow was checked, the appetite was improved, and her natural buoyancy of spirits was rapidly returning. In eight weeks the neck was two and a half inches smaller, and the pulse was reduced under 100, except under great excitement by fast walking up-stairs and the like. In thirteen weeks the neck was not noticeably enlarged, and the exophthalmos was so slight as to be unimportant. It remains about the same now, two years after her recovery, and no one would see anything peculiar in her appearance. The collar fits her loosely at thirteen inches. After the third month the applications of the battery were reduced to bi-weekly, with short séances of from five to ten cells, and at the end of six months she was discharged and considered herself cured, in which opinion I concurred, and nothing has as yet led me to alter my idea. She remains unmarried, and what may result from a change in her sexual relations remains to be seen,—a matter of interest to me, as the next case undoubtedly shows that in some persons, at least, sexual excitement has an unfavorable effect upon Basedow's disease.

F. A., 20 years old, consulted me because of a gradual enlargement of her neck, and, as her mother had for many years labored under a fibro-cystic goitre, she became somewhat anxious as to the probable outcome of the deformity, especially as she was shortly to be married. The lady was a victim to neuralgic dysmenorrhœa, with cervical uterine congestion, and associate leucorrhœa, which appropriate local treatment relieved. Her dysmenorrhœa was greatly reduced by quinia and arsenic, but her goitre, although not decidedly worse so far as thyroid protrusion went, was aggravated by all the symptoms of the exophthalmic type within six months after coming under my care. Space need not be taken to describe her symptoms in detail: suffice it to say, her marriage was postponed. She was placed upon full doses of digitalis and iron, all exciting causes restrained, and under this, with the continuance of the arsenic and quinia, to which ergot was shortly added, in a few months her most aggravated symptoms were relieved. Every indication of a speedy cure being observed, for good reason her nuptials were permitted. For several weeks preceding her marriage, the disease was to herself, her parents, and myself daily disappearing; it was most certainly at bay. On her return from the bridal tour, three weeks subsequently, in every particular she was worse; the neck was again enlarging, the pulse was up above the hundred, the eyes were staring, carotid pulsation was overmarked, and rest from any but the slightest exercise was imperative. Although no uterine disease existed, beyond a little pre-menstrual pain, every act of coition intensified the cardiac disorder, and the increased swelling of eyes and thyroid alike were pronounced at my morning visit, had this act occurred during the preceding night. The neck, by careful measurement on such occasions, was enlarged a full half-inch, and remained so for about forty-eight hours, when it would disappear, or return, strictly speaking, to the usual circumference as existing before the sexual intercourse. It does not appear that this aggravation was due simply to ex-

citement, because sexually neither of the parties was unduly ardent either before or during the act, nor did any exhaustion follow cohabitation, such as would present itself under undue stimulation. The phenomena to me were strictly due to reflex action through the sympathetic. Marital relations in this respect were suspended, and all medicines stopped. She was placed at once under galvanism daily, but, unlike the first-noted patient, she bore easily twenty or thirty cells without discomfort. The applications were managed as in the case of Miss E. M. H., and were kept up for one month, when very decided improvement was in all respects manifest. Intercourse was permitted for a few times without apparent ill results, but then stopped, and the electrical treatment reduced to four applications each week, and at the end of four months she was completely free from any evidence of her original difficulty. She has had no return in now nearly two years, but she either has, or imagines she has, a fulness of the throat always during the morning succeeding connection, especially in case of previously prolonged abstinence. Her menstrual derangements are gone, and her general health is excellent. She has never been pregnant. Although *temporary* increase of size in the thyroid gland under sexual excitement has been referred to by a few writers, the fact is generally unknown to the profession at large, and, as I am fully satisfied—not alone from this case, but from other sources of information—that such is the fact, I note the point particularly.

Mrs. S. L. was referred to me by a friend, with a view to treatment by electricity. She had been a sufferer for something over two years, and was becoming worse daily. The pulse *averaged* 120, eyeballs were decidedly prominent, palpitation and cardiac hypertrophy pronounced, the neck increased by three and one-half inches, menses in abeyance, and general health visibly reduced. She had been under good professional care both by her own regular attendant and his *confrère*, but recovery seemed uncertain, the disease holding its own for some months before I saw her, and a repulsion being developed towards further medication. Faradism had been tried at one period in her progress without benefit, but the method and mechanism employed were not reliable. She declared herself, however, relieved of much oppression for an hour or two after these applications, and to fully test the matter she was thoroughly treated by induction currents, locally and generally, for one month, nothing else being done beyond attention to diet and rest. There was now an evident amelioration, not alone of her distress, but her personal appearance was obviously improved; yet, although satisfied with this gain, it was deemed better to adhere to galvanism as in the first two cases narrated, because of its more rapid action as a curative agent and its undoubtedly greater adaptability for the end aimed at. Double the benefit at least was attained at the end of the next month under the constant current as compared with the faradic. Without entering into details, which would merely recapitulate largely what has already been written, suffice it to say that in four months she was apparently in her usual health as before the advent of her goitre. There yet remains some cardiac hypertrophy, but palpitation is rare, even under excitement. Beyond this she would stand rigid examination without fault being detected. Menstrual disturbances were frequent before her illness, now none exist. For eleven months she has remained well and able to see to her family cares, which are somewhat exacting.

A single swallow does not make a summer, and these cases, although good examples of the value beyond question, in my opinion, of electrical treatment, do not, of course, suggest that other means are unreliable and that this method is infallible. I am aware that electricity has failed in competent hands to relieve, or rather radically cure, exophthalmic goitre, and that undoubted cures have been wrought without it, but it has its place, nevertheless, in therapeutics, although, like many another good thing in the long array of remedies, it lies buried out of sight to the majority of the profession. The empirical manner of its use in disease has led many thoughtful men to reject it, and the inherent difficulty of rational employment and care of apparatus deters others from thoroughly testing this invaluable ally. Doubt has also been expressed by gentlemen supposed to be familiar with practical electro-therapeutics as to successfully reaching the sympathetic, particularly in the solar plexus, by any form of current; and as intelligent operators are opposed to hap-hazard methods

of any kind, it may be that the failures alluded to above have arisen from doubts of this nature, or from a loose attention to the procedure, if tried. From the anatomical arrangement of the neck, it follows that in influencing the cervical sympathetic the pneumogastric also must be involved, and it only needs well-conducted experiments to show that the heart, and therefore the entire circulation, is readily acted upon by either current. To myself the galvanic seems the better adapted, it being prompter in action, more comfortably borne, and showing more definite and durable ultimate results. Although not at all affected by goitre of any kind, I have suffered from functional palpitation for many years, and at all times the cardiac excitement is readily controlled by moderate currents of from twenty-five to forty modified Daniell's, developing an electro-motive force of from eight to twelve milliwebers. That the sedation is not resultant from preconceived ideas of my own is evidenced by precisely similar effects being had in patients under treatment for other affections, whom I always utilize experimentally whilst able to do so. Whilst galvanism at times stimulates the heart to increased action in a limited way, its ultimate action, even in such persons, is to soothe; and no better test can be made than to personally undergo general applications before retiring, after an exhausting day's work, or when ruffled by the cares of serious cases or the quips of ill-natured and ungrateful people (if you are open to such impressions). Other cases in the practice of friends, which I have been favored with seeing, and which were managed in whole or in part as described, have terminated favorably, and in exact proportion as the electrical manipulations were more or less perfect.

Since the above was in type, a case at present under my charge, which is satisfactorily progressing towards recovery, has been treated by *static* electricity, the machine employed being a "Toepler" modification of the well-known Holtz apparatus. The patient is insulated, thoroughly charged by Radcliff's positive method, and sparks drawn from the thyroid. Galvanism is, as usual, mainly relied upon, but there is without doubt a notable acceleration in her recovery since instituting treatment by *static* applications. A report of several cases of varying nervous affections thus treated was published in another journal recently, and results of further investigation in this direction will be given in a future article.

246 North Twentieth Street.

THE DEFECTS IN OUR PRESENT MEDICAL EXPERT TESTIMONY; WITH A PROPOSED REMEDY.

BY JOHN J. REESE, M.D.,

Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania.

THAT the medical expert testimony of the present day is defective in many particulars is a fact so generally admitted by both court and counsel as to have occasioned a very general distrust in such evidence among the legal profession. This is unfortunate, since very often, in criminal cases more particularly, the testimony of the well-instructed medical expert may shed a flood of light upon abstruse and difficult points, which otherwise could not be understood by either court or jury. Whence arises, then, the apparently growing distrust of this sort of evidence in the minds of men whose whole mental training leads them to subject every sort of testimony to the most rigid scrutiny? I think the answer to this question may be referred to two causes: *the character of the experts themselves*, and *the vicious mode of using such testimony by counsel.* On each of these points I desire to offer a few remarks.

First, as to the character of the expert. I particularly refer to his *professional* character. I need hardly stop here to remind the reader that an "expert" witness differs from an ordinary witness, in not testifying to mere facts,—such as what he has seen or heard of the case,—but he gives his *opinion* on the facts testified to by others. As the term implies, the "expert" must be *skilled* in the particular matter in which his testimony is required: he must have made it his special study. But how many of our criminal trials, especially, are disgraced and degraded by what has been sneeringly termed the *war of the experts!* It is a notorious fact, that in nearly every criminal trial, and in many civil cases involving the question of insanity,—particularly will cases,—it has become too much the fashion to pit one medical expert against another; sometimes there may be several on either side, each one deliver-

ing his "opinion" diametrically opposite to that of his opponent. Undoubtedly this defect is partially to be ascribed to the faulty manner in which these experts are employed by counsel; but it is much more largely due, in my opinion, to the faulty character of the experts themselves,—the incompetency of the individuals who have voluntarily thrust themselves into this responsible position. For, be it remembered, neither the mere title of doctor, nor even the well-earned reputation of the general practitioner, does by any means imply proficiency as an *expert*. For example, in a homicide case, involving the life or death of the prisoner, where the main evidence of the prosecution depends upon the identification of certain suspicious stains upon the clothing, or upon a weapon discovered close by, who but the well-practised microscopist shall presume to solve the all-important question? So, in a poison case, who but the practised toxicologist shall venture to give an "opinion" as to the real cause of death, or of the nature of the alleged poison? Who but he is competent to decide the finely-balanced question whether the symptoms and pathological appearances were really due to poison or disease? And who but he shall presume to criticise the chemical analysis, and detect and expose the blunders of careless and incompetent experimenters, which, but for his sagacity, might have doomed an innocent victim to death?

All this is plain enough; nobody will dispute it. Yet the fact remains as notorious as ever that medical men of excellent general professional character, but who have not made these branches of science subjects of special study, are tempted to place themselves on the witness-stand, in certain grave trials, in opposition to others of acknowledged skill and reputation; and the lamentable result is that as the court does not, or will not, see the difference between the good "expert" and the bad,—the genuine and the false,—being already prejudiced against all alike, it will treat all alike; and regarding one as good as the other, it will so state it to the jury in the final charge. This is no fancy sketch: I have known the counterpart in my own experience, in a case in which the prisoner was convicted and sentenced to punishment upon just such "incompetent" expert testimony, as was afterwards abundantly proven. Now, can any one doubt that, if *all* the experts engaged in any cause were persons of equal skill and experience, there would be far less likelihood of a conflict of opinion, than where some ignoramus, confiding in his general knowledge, unhappily displays himself for the occasion, and undertakes to differ from his acknowledged superiors on the other side? If, for instance, *all* the experts concerned in a poison-trial were men equally well grounded in every department of toxicology, as also in their general training as physicians, it is scarcely conceivable that they should differ much, if at all, as to the proper modes of testing, and as to the results attained. Certainly we should then witness nothing of the disgraceful "war of the experts," before alluded to.

Another well-founded allegation is that in certain criminal and will-cases, experts are sometimes selected by opposing counsel expressly for the purpose of supporting particular views, on account of their known bias to some "hobby" or preconceived notion. This is unquestionably a great evil, and if not remediable, it might of itself be sufficient to destroy all faith in medical expert testimony. But is it remediless? We may hope not, since the cure for it seems simple enough, namely, that *all* who undertake to act as experts shall be thoroughly *skilled* in the matters on which they are to give testimony, and shall be completely free from any bias or prejudice. Another part of the cure consists in the avoidance by counsel of the vicious practice above alluded to. Occasionally, however, the difficulty would seem to be with the court, doubtless through some distorted ideas on the subject. Thus, I have known, in a certain criminal case, in which there happened to be two medical men acting as experts on one side, and but one on the other (although the latter was admitted to be the more thoroughly trained witness, both by practice and position), the judge took the ground, and told the jury, that one expert was just as good as another; and that, as in this case there were two against one, the majority ought to carry the day; and so he ruled!

There is a graver fault still, chargeable against medical expert testimony, though we may hope it is not so prevalent as the others, namely, where the experts make their views the subject of barter to the parties employing them, and where their fees are made "conditional" on the influ-

ence of their testimony. Certainly such dishonesty cannot be too severely reprobated. But I would state my convictions that no medical man of principle would ever lend himself to such dishonorable traffic. That such instances may have occurred, I do not undertake to deny; unhappily, the medical as well as the legal profession is occasionally disgraced by such unprincipled charlatans, who not infrequently connive together in their nefarious work.

It has always seemed to me that the true method for the expert to pursue, before engaging in any case, is to make himself thoroughly master of all its bearings. Suppose, for example, that his services are desired by the defence in a poison case, or in any other case of homicide. Before consenting to undertake it, he should carefully examine (which he is privileged to do) the sworn reports of the physicians who made the post-mortem and chemical examinations of the deceased, together with the line of treatment adopted. If, in his opinion, from the character of these investigations the charge of murder cannot be logically sustained, either through a defective autopsy, a careless, imperfect, or unskilful chemical analysis, or an improper medical treatment, then he is not only justified in taking up the case for the defence, but he can hardly escape the responsibility of not so doing, since otherwise a most grievous wrong might be perpetrated upon a possibly innocent being.

The important question now occurs, Is there no remedy for these admitted evils in our present medical expert testimony? I reply, None in our country, as the law stands at present. With us, the courts exercise the greatest latitude in the matter of medical experts, allowing the title and the prerogatives to any and every person who has assumed the name and profession of doctor. To be sure, the stereotyped question is usually put to the witness offering himself as an expert, if he has given particular or special attention to the matter now under consideration? but, of course, the ambitious witness always supposes that he has done so, and gives an affirmative reply. But there is no positive guarantee that this is so; indeed, in the majority of cases the chances are against it.

The only true method, it seems to me, of meeting the difficulty is to adopt an arrangement somewhat similar to the Prussian system, which is admitted by all legal physicians to be the best known, although perhaps not absolutely perfect. A modification of this, I think, might readily be engrafted upon our American practice, somewhat after the following plan. Let there be appointed by the proper authorities, for each of our States, one or more thoroughly educated practical physicians, properly trained in all the details of medical jurisprudence, including toxicology. These shall be known as the "State Medical Experts." The duties of such an official shall be to attend at every criminal trial in his district, when summoned by the court, *as the skilled witness of the prosecution.* He shall sit with the judges throughout the trial as the *amicus curiæ*, giving special attention to such points as may require the professional assistance of medical experts, so that he may enlighten the court and jury on the technical aspects of the case. He shall be prepared to make all the requisite medical, microscopic, and toxicological investigations in any case requiring them. Thus, in poison cases, the district attorney would be saved the annoyance and expense of hunting up a suitable toxicologist. By his expert testimony the prosecution would always be guided. There would be no necessity of appeal from his decision.

He should possess a chemical laboratory, and all other appliances necessary to the thorough fulfilment of his duties. Although summoned by the State, he is by no means to be regarded in the light of a partisan, any more than the judge upon the bench. He can have no temptation to a bias for either side. He would render his "opinion" grounded solely upon truth; and both his moral and professional character and acquirements should be such as to preclude the possibility of error, so far as human infirmity may admit.

In most criminal trials the testimony of such an official expert, commanding, as he ought to do, the respect and confidence of all parties, would be deemed fully adequate to settle all scientific questions by both sides,—the defence as well as the prosecution. But there would, doubtless, arise some cases in which the defence would claim the right (which, of course, should always be conceded) of employing their own expert witnesses. This, however, need not in the least interfere with the State officer, since, if the former be thor-

oughly competent experts, they will be the less likely to differ with the latter, as I have before attempted to show; and even if they should perchance differ with the State expert, the prisoner would still enjoy all the advantages which he would possess under our present system.

In States as populous as Pennsylvania, there should, I think, be at least two State experts,—one for the eastern and one for the western district. The salary of such an official should, of course, be sufficiently ample to command the very best talent, inasmuch as the medical officer would necessarily be compelled to relinquish all practice, and devote his time exclusively to his arduous State duties. But even in an economic point of view the State would probably be the gainer, inasmuch as the aggregate yearly amount which the various counties of the State are compelled to pay out for toxicological and other professional examinations in their respective criminal trials, would equal, if not considerably exceed, even a liberal salary allowed to the State expert.

Two difficulties only present themselves to my mind in the way of practically carrying out the above system in the different States of our country, and these, I believe, are by no means insuperable. The first and greatest difficulty, I presume, would be in the mode of appointment of the State official. Unquestionably, such a dignified office should be lifted high above all political favoritism. It should be bestowed only upon the most competent. But who shall decide this most important question of competency? Obviously, *not* the legislature, for it can have no means of judging of qualifications of such a character, except through the representations of constituents; and everybody knows that all such representations must partake largely of the worst forms of political bias. Neither should the responsibility be laid upon the governor of the State, for a like reason. The State Medical Society might by some be deemed the proper body at least to suggest the suitable appointee to the civil authority; but I fear that there might be, even in this most respectable body, some risk of cliquism, ring-influence, or favoritism. On the whole, I believe that the safest body with whom to lodge the responsibility would be the judges of the Supreme Court of the State. Their high official position places them, almost certainly, beyond the risk of foreign sinister influence in such a duty. They might act in full council, after due consideration of the merits of the different candidates, and their decision, to be determined by ballot, would doubtless be regarded as impartial, and would be accepted as satisfactory by all.

The other objection (as some might consider it) might be the difficulty, and even, at times, the impossibility, of the State expert's being able to answer all the calls of the different criminal courts of his district. Of course he could attend only one at a time; and a difficulty would arise if two or more trials were going on simultaneously. This would have to be remedied either by the appointment of additional State experts in very populous districts, or by a mutual arrangement among the different county criminal courts, so that the cases might not interfere with each other.

I have given to this subject of Medical Expert Testimony considerable thought and attention, and from a pretty extensive experience I am led to believe that the plan above suggested, with possibly some modifications, is the one best adapted to remedy the evils of our present imperfect system. I should be glad if these remarks would have the effect of stimulating the ideas of such of the readers of the *Medical Times* as feel an interest in this most important subject, so that we might have the benefit of their views in a future article.

316 South Twenty-First Street.

CARBOLIC ACID APPLICATION TO ERYSIPELAS.

BY S. J. RADCLIFFE, M.D.,
Washington, D.C.

AN abstract in the *Philadelphia Medical Times* of February 26, translated from an article in the *Deutsche Med. Wochens.* of January 22, under the title of "Carbolic Acid Application to Erysipelas," giving a formula "which has been employed for several years by Dr. Rothe, of Altenburg," to arrest the course of erysipelas, reminds me of a severe case of erysipelas of the right lower extremity (E. ambulans?), just convalescent, in a woman, Irish, of good constitution, but rather feeble from age, over eighty years old, which began as a central point in a large, inflamed bunion on the metatarso-

phalangeal articulation of the right great toe and extended over the entire limb to the abdomen and over the buttocks, a large bed-sore rapidly forming over the sacrum, which was treated successfully with carbolic acid and olive oil, after other applications had seemed to fail to benefit the case.

I first saw the case February 3. She had been suffering for some days from a large inflamed bunion on the large articulation of the right great toe, which the family undertook to treat with some simple remedies. Finding the condition of the woman getting materially worse, the toe and foot assuming an alarmingly erysipelatous condition, I was sent for.

I found the foot and leg, up to and a little above the knee, uniformly red, shining, tense, hot, tender to the touch, and largely swollen, the cellular tissue and the derma infiltrated and pitting on pressure, pulse 98, temperature 101.5°, tongue furred, mouth dry, thirst, bowels open, urine not free, high-colored, depositing urates, some hebetude, and considerable indifference as to her condition, especially as to her evacuations, which she would pass involuntarily if not watched.

The case looked so unpromising, considering her age and surroundings,—though I had seen her come through safely several severe attacks of illness,—that I notified the family of the danger attending the disease and of the small chance she had to survive the attack.

I began the treatment, as is my custom, with non-irritating applications to the inflamed parts, such as wheat flour, starch powder, or zinc oxide and starch powder,—believing these, after much observation and experience, to be the best,—directing the zinc oxide and starch powder, as in this case, to be thickly and thoroughly dusted over the surface with an ordinary powder-puff, and ordered the conventional muriated tincture of iron and sulphate of quinine to be given every three hours, alternated with half-ounce doses of the liq. ammoniæ acetat., and fluid diet of milk and beef-tea.

I continued this treatment until the fourth day, with no apparent amendment of the symptoms, the erysipelatous inflammation having advanced, step by step, by gradual and distinct extensions, above the knee to the middle of the thigh, large red spots appearing above, and the lower borders approaching and filling in the healthy skin, and the lymphatics were swollen and tender and the glands enlarged. I now directed the foot and lower part of the leg to be enveloped with lint saturated with dil. sol. lead acetate, continuing the dusting the rest with the zinc oxide and starch powder, and continuing also the iron and quinine alternated with 10-gr. doses of sodium sulphite, and the same diet.

On the seventh day the inflammation had extended above the groin by distinct, advancing, isolated patches of redness, some large spots of redness appearing on the lower part of the abdomen and over the buttocks, a large bed-sore having also rapidly formed over the sacrum without the knowledge of the patient or even the nurse, and which was accidentally discovered by turning her over.

The limb was now of a darker, duskier hue, not so shining or red, but enormously swollen, with a feeling of burning and weight, and doughy, leaving deep impressions in parts on pressure, which would remain some time, with numerous small vesicles scattered over the limb, and the whole contour had the appearance of approaching gangrenous condition.

I then ordered an application to be made freely with a large, soft feather of carbolic acid ℥ii to olive oil ℥iv, the parts to be covered with lint, the dressing to be repeated three times daily, the other parts about the abdomen and anus to be protected and dusted as before, and the medicine and diet continued.

Relief began almost at once. The next day amendment was plainly evident. The swelling gradually subsided, the redness soon faded away, and by the tenth day the limb was reduced to almost the normal size, the cuticle peeling off in large flakes irregular in size and shape, some an inch or more in breadth, leaving a healthy condition beneath; and the bed-sore was in a healthy condition and healing well.

The pulse ranged during the treatment from 98 to 110, and the temperature from 101.5° to 103.5°. Much thirst was manifested throughout, with some febrile exacerbation during the evening, showing considerable constitutional disturbance, though rather of an adynamic type. The patient was very indifferent as to what was done for or given her until towards the last, when she exhibited great desire to recover.

I ceased to visit her regularly after the twelfth day, after which date she convalesced rapidly.

The points of interest in this case are—1, the age of the patient; 2, the persistent spread, extent, and malignancy of the inflammation; 3, the bed-sore forming in so short a time; 4, recovery apparently through the agency of carbolic acid. Rarely, I think, are conditions such as these presented in a single case of this description; and it is for this reason that I offer it for record.

1211 F St., N. W.

CASE OF STIFF KNEE CURED BY FORCIBLE FLEXION.

BY GEORGE HAY, M.D.

ABOUT the middle of December, 1880, S. C., a man aged 38 years, called at my laboratory. At that time he was employed in one of the floating coal-offices on the Alleghany River as a species of shipping-clerk and to make himself generally useful. He stated that about the last week of November, or about three weeks previously, he and another man were using a lever to pinch what is called the "apron" or gangway away from the float, which had by some means got "fouled." The other man suddenly released his hold upon the lever, and, the whole weight of the "apron" being upon the other end, S. C. was thrown upwards to a height of fifteen feet, from which height he fell upon his left knee. According to the man's own story, there had been considerable effusion of fluid into the synovial sac, but when I saw him (three weeks after the accident) the fluid had been entirely absorbed. The patella appeared unusually large, but, on examining for comparison the uninjured knee, I found that such was its normal condition. The patella was freely movable over the joint. On examining the joint itself, I found that the internal condyle of the femur seemed larger than usual, but could not make out any intercondyloid fracture. The leg was completely extended, and the patient could not flex it at all. Fixing the thigh firmly by placing the patient face downwards and sitting astride his thighs as if on horseback, I found that by using considerable force the extremity of the limb at the great toe could be made to move through an arc of about three inches, the centre of the circle being an ideal point in the articulation of the knee. This, of course, implied but little motion in the knee-joint, but at the same time demonstrated the absence of ossific union of the bones, and led me to conclude that the anchylosis was only fibrous.

At this time I was serving on the staff of the Pittsburg Free Dispensary, and, as the patient was very poor, I advised him to come thither the following day, and stated that I would try to secure him a movable joint. Next day the man was laid face downwards upon the table at the Dispensary; I sat astride his thighs, and, using my utmost strength, both hands at the ankle, I forcibly flexed the leg upon the thigh and broke up the adhesions, which snapped audibly. I advised the man to get upon his knees every morning and evening, and prescribed a cooling lotion. In about a week I visited him at his home and found the joint stiff again, but not so much so as formerly. Again I broke up the adhesions forcibly, and prescribed an embrocation of oil, chloroform, ammonia, and camphor, regard being at the same time paid to his general health. I told him to get a crutch; he said he was too poor to buy one. I called upon his employers and asked them to furnish the man with a crutch, as he had been hurt in their service; they never did so, but, with the characteristic meanness of the average employer, they soon after discharged the man from their employ. Improvement, however, was rapid after the second forcible flexion, and now, nearly four months after the injury, the joint is quite as movable as that of the other knee. There is even yet slight thickening of the internal condyle of the femur, but it is diminishing; pain has disappeared, and the man can walk as well as ever he did. So far as I am aware, the books do not recommend such treatment as above described, and there are, no doubt, many cases in which it would not be advisable; but these would require to be carefully discriminated from those in which it would be suitable.

Analytical Laboratory, 45 South Diamond Street, Alleghany City, Pa.

CHRONIC COPPER-POISONING.

BY JOHN GILLESPIE, Jr., M.D.

THE following case is of some interest from the fact that the symptoms ensued upon employment in one of the arts, and because it presents some features which differ from those usually said to occur in a case of this nature. Further, it shows, negatively, the value of so simple a precaution as wearing a sponge before the mouth.

On account of the rapidity with which the symptoms supervened, it partakes of the acute character, although it is probable that the sore throat was caused by the particles of the powder acting mechanically.

N. C., æt. 35, was admitted to the wards of the Pennsylvania Hospital under Dr. James

H. Hutchinson, January 24, 1881. Three weeks previous to this the patient had begun working in a lithographing establishment, her work being to gild the lithographs. The powder used (bronze-powder) is largely composed of metallic copper.

The other work-people wore sponges over their mouths, but, through ignorance, the patient neglected to do so. After a few days her throat became sore, and she was troubled with a severe cough, but suffered no other inconvenience until three days before her admission to the hospital, when she was attacked with very severe pain in the abdomen, and vomiting, but no diarrhœa, the bowels being constipated. After the first day there was no vomiting.

Upon admission, the patient was anæmic, and there was a bronze discoloration of the face and hands. The hair was dry, the abdomen was greatly distended, and there was severe pain referred to the region of the umbilicus. The bowels were constipated. Neither the teeth nor gums presented any appearance of the green line said to be present by Dr. Clapton,* but, on the contrary, there was a faint purple discoloration of the gums, as is said to occur by Sir D. Corrigan.† The sleeves of the underclothing near the axillæ and at the elbows were stained green. There were headache and slight dizziness, with muscæ volitantes.

During the entire period of the illness there was no fever. The urine was examined for copper, but none was detected. The fæces when first voided were of a greenish hue, but, on exposure to the air, became dark red. Copper was detected in the fæces by the following process. A mixture of equal parts of fecal matter and nitric acid was evaporated and strongly heated, more nitric acid added, and the evaporation repeated several times. The residue was then exhausted with distilled water and filtered, and the filtrate tested by the usual methods.

The treatment consisted of the exhibition of magnesium sulphate half an ounce twice daily, and seven drops of the deodorized tincture of opium every four hours to relieve the pain. Abundance of milk was given as the principal food for several days.

The patient was discharged cured February 14.

1332 South Broad Street, Philadelphia.

Sudor Anglicanus.—An epidemic of the curious malady known as sudor Anglicanus (*suette miliaire*) has been reported as occurring in l'Ile d'Oleron, France. One hundred and forty deaths occurred among twenty thousand inhabitants.

PSORIASIS IN A CHILD UNDER FOUR YEARS OF AGE.

BY H. W. STELWAGON, M.D.,
Physician to the Philadelphia Dispensary for Skin Diseases.

As is well known, the first attacks of psoriasis occur most frequently at or approaching the time of maturity. Down to the age of ten it is not uncommon, but below this period it becomes very infrequent. Its occurrence in a child of five or six years is extremely rare, and in children under four years but few cases have been reported.

The following case came under my care during the early part of last year, and, as the subject was a very young child, it is worth recording:

The child, a male, was in its fourth year (lacking three months of being four years old), was well nourished, robust, and of healthy parentage. So far as could be ascertained, there existed no hereditary tendency to psoriasis, although one of the parents had been the subject of an occasional attack of eczema during early life.

On the trunk, arms, and legs were numerous scaly papules about the size of a split pea. On the back were several patches of the diameter of a ten-cent piece. On the extensor surfaces of the elbows and knees the patches were confluent and the disease well marked. The eruption was but slightly inflammatory. The scales were abundant, and of the peculiar pearly color so characteristic of psoriasis. The eruption had first appeared on the extensor surface of the elbows about nine months prior to my seeing the case, the child being then just three years old. Subsequently the knees were likewise attacked, where, as on the elbows, the patches at a later stage became more or less confluent. Afterwards other regions of the body were affected. The larger patches seemed more inflammatory. With the exception of the patches on the elbows and knees and the few on the back, the eruption was typical of the variety known as psoriasis guttata. Mere removal of the scales from some of the larger patches would cause slight bleeding at points; on others, however, this was not so easily produced. Itching had been troublesome at first, but had apparently ceased to be of much annoyance. The case had already been once under treatment at one of the dispensaries, but without much benefit,—doubtless due to the negligence of the mother.

The child was ordered small doses of Fowler's solution three times daily. The case was under observation, at intervals, for three months, and then disappeared from notice. During this time treatment was but spasmodically carried out, and, necessarily, with but little, if any, improvement.

NOTES OF HOSPITAL PRACTICE.

HOSPITAL COLLEGE CLINIC, LOUISVILLE.

SERVICE OF PROF. DUDLEY S. REYNOLDS, M.D.

Reported by A. H. KELCH, M.D.

CASE I.—Theodore Merkel, æt. 49, has suffered for the last three years from a disease of the throat and ears. He has been greatly annoyed by roaring and buzzing sounds, and occasional earache, sometimes amounting to acute pain. You may remember that when he was here first I found him suffering with what is generally called an acute catarrh, but what is in fact a subacute rhinitis. You may remember also that I announced to you, after examining his ears, that the drum membranes were collapsed. This condition was brought about by narrowing of the faucial orifices of the Eustachian tubes: the external atmospheric pressure upon the tympanic membrane being greatly in excess of the pressure within the drum cavity, the membranes of course, yielding to the superior external pressure, became gradually depressed. This condition of itself was sufficient to account for the earache, and, in fact, all the pain with which he is often tormented. Narrowing of the Eustachian tubes is always present in inflammation of the lining membrane of the naso-pharyngeal spaces. Now, catarrhs become chronic in debilitated subjects only. Mr. Merkel is a tailor by trade; he sits upon a bench in a close room, breathing a vitiated atmosphere, and it is no wonder he suffered from catarrh. His sedentary habits alone are sufficient reason for the persistence of local inflammations in the nasal and naso-pharyngeal and, for that matter, the bronchial mucous membranes. Mr. Merkel was during the first year or two afflicted greatly with cough; his voice gradually failed, until he was finally unable to engage in anything like satisfactory conversation. You remember when he came here it required great effort upon his part to vocalize, and close attention upon your part to understand what he said. He spoke with so much difficulty that the interval between words amounted to several seconds, in some cases quite a quarter of a minute; his articulation was bad. Examination revealed what appeared at the time to be paralysis of the left vocal cord. His trachea contained no morbid secretion. The lining of the nose, however, and naso-pharyngeal space was the seat of considerable inflammatory deposit. He had lost a portion of both inferior turbinated bones. Now, in the presence of all these morbid conditions, it is reasonable to infer that Mr. Merkel's disease began with constitutional debility, with these varied favorable conditions for the development of a parenchymatous rhinitis kindled from an acute catarrh due to purely atmospheric causes. Mr. Merkel's profession would forbid his engaging in anything like regular conversation. It necessitates that the head shall be inclined forward: the chin making pressure upon the larynx, renders conversation unpleasant. Therefore, from long habit, he has talked but little, until, finally, with the disease augmenting occasionally in severity, his ears becoming affected, his disposition to engage in conversation has grown gradually less and less. Not hearing acutely, he naturally felt inclined to avoid conversation, lest other persons should become aware of what was to him beginning to be a serious affliction. When he first came here I introduced the Eustachian catheter, and, with the aid of Politzer's air-bag, inflated the drum cavities of both sides. Since that time the process has been repeated at intervals of a few days, and he is now able to hear almost perfectly. You observe to-day he gives prompt answers to my questions; he speaks readily, and with as much clearness as most persons. The mere inflation of the tympanic cavities with air is not to be credited with all the improvement manifest in Mr. Merkel's hearing. The swollen, indurated condition of the naso-pharyngeal membrane has been greatly reduced by an occasional injection with the post-nasal syringe with a saturated solution of the muriate of ammonia. In addition to this, Mr. Merkel has been snuffing finely powdered white sugar, which acts as a gentle stimulant, and which has proven in his case of great service in bringing about resolution in the inflamed membrane. To stimulate the relaxed vocal cords he was directed to make use of benzoic acid lozenges made after the formula of the London Throat Hospital Pharmacopœia. The lozenges were taken one every four hours, and he has had an occasional dose of quinine. He has been directed to take salt-water baths at night, and to take an abundance of animal diet. To all these agencies com-

bined I attribute the improvement you now observe in his condition. To-day he hears well, his voice is good, his articulation wellnigh perfect; and, there being no longer any evidence of local disease in the nasal, pharyngeal, or laryngeal mucous membranes, the vocal cords appearing upon examination to be perfectly normal, Mr. Merkel is discharged, with the injunction to return to this clinic in the event he should again suffer the slightest symptoms of a return of his disease, either in the ears or the vocal organs. This is a case showing the necessity for minute and careful instrumental examination in order to make the proper diagnosis, and of course you understand that in the absence of a correct diagnosis the treatment must needs be irrational. I beg you never to believe for one instant that tinnitus aurium, atony of the vocal cords, and other similar phenomena are indicative of central lesions of the nervous system, until after you have made careful local examination of the parts affected. Now, it sometimes happens that in cases of syphilis all these phenomena occur, along with what appears to be a subacute inflammation of the naso-pharyngeal membrane; but in that case there will be more or less of local deposit, which distinguishes syphilis from almost all other forms of disease. Again, the local treatment will offer no substantial relief in syphilitic cases. You will, therefore, be able within a few days to determine the correctness of your diagnosis by the success of the treatment.

Case II.—Mrs. Y——, in April, 1879, came to me with plastic irido-cyclitis, floating masses of lymph in the vitreous chamber, a total blindness, with the slight exception that she was able to perceive light. The instillation of a few drops of a four-grain solution of atropine revealed the presence of posterior synechia. She had been suffering with great pain, was much emaciated, and quite nervous. She had suffered with violent temporal headache every day at particular hours, the pain lasting just so many hours, and gradually subsiding, leaving the patient much exhausted, when profuse perspiration would ensue and she was inclined to sleep. She had suffered from constipation of the bowels and greatly diminished appetite for three months before I saw her. There was upon the surface of the iris a number of yellowish tubercular elevations. These nodules were formed by the local deposition of plastic material. Now, I wish to say that these plastic nodules upon the surface of the iris or projecting from the pupillary margin I believe to be characteristic of syphilis. Whilst these are not present in all forms of syphilitic iritis, there can be little doubt of the syphilitic character of those forms in which the plastic nodules are present.

Mrs. Y—— had been unhappily married, and for a year had not lived with her husband. I asked her no questions, but, taking the peculiar manifestations of the disease in the iris as sufficient evidence of the syphilitic character of the disease, I at once prescribed iodide of potassium in ten-grain doses, ordered a saline aperient, and directed her to have five grains of the sulphate of quinine in solution three times a day before eating, and in addition to this she was ordered to use a four-grain solution of atropia every four hours. She was ordered a pair of London smoked coquille glasses to protect her sound eye from the light, and some general directions as to diet, etc., were given. Improvement began within the first few days, and she rapidly recovered from all signs of local disease, except impaired vision in the affected eye. She was, however, able, after a few weeks, to count fingers across the room, and finally to read $\frac{20}{LXX}$. I lost sight of her until a few months ago she came to say her vision was gradually becoming dim in this right eye. Careful examination disclosed the presence of minute opaque spots in the capsule of the lens, whilst the lenticular body itself showed opaque striæ. I saw her two weeks afterwards: the opaque spots in the lenticular capsule were greatly augmented in number and enlarged in size; the opaque striæ before visible in the lens had now given place to a distinctly marked and diffuse opacity. The eye was sensitive to light, and there was excessive lachrymation. The patient's general health was impaired. She was having quotidian headaches, and suffered from diminished appetite and from constipated bowels; the menstrual function had been disturbed; she appeared anæmic; her skin was rough, and discolored in places, presenting a slate-colored appearance. What appeared to be a proper course of constitutional treatment was at once begun, and an occasional drop of a four-grain solution of atropine was instilled into the eye. The general health improved, the photophobia and lachryma-

tion ceased, and she is here to-day to request the extraction of the cataractous lens, not with the view of restoring sight, because I have warned her of the improbability of any such result, but she wishes the lens extracted from this eye for cosmetic effect. She has consented to permit the operation without chloroform. Placing this speculum between the lids, I now proceed to make what is known as the peripheral corneal section. Introducing my knife in the horizontal line on the temporal side, I pass it forward until the point reaches the pupillary opening, when, by a slight depression of the point of the instrument, I engage the capsule of the lens, which I find very tough and resisting. The knife, however, now passes on, and I begin the counter-puncture in the horizontal line at the nasal side of the cornea, and by passing the knife rapidly on, you see, I complete the section. The iris floating in between the lips of the wound, I now seize it with the forceps and cut off about one-sixth of it with the scissors. The lens now presents itself, and by light pressure with the convex surface of Daviel's spoon upon the inferior margin of the cornea, the edge of the lenticular body engages the corneal wound above, and, you see, I readily tilt it out, and deliver it from the eye. I now, by gentle and careful manipulation with the spoon, cause the cortical portion of the lens-substance to flow into the central portions, and by gentle pressure cause it to escape from the wound, thus leaving a clear pupillary space, except for the plastic deposit in the substance of the capsule. You see now the operation has been done, and without great pain, as the patient has made no complaint whatever. I shall now proceed to close this eye with some dry cotton wool and strips of adhesive plaster, the dressing to remain for a week, unless some pain, or other evidence of local irritation, should make it necessary to remove it. Now, this operation was not done to restore sight to the blind eye, but to remove what to the patient was a source of great annoyance,—a white pupil. The operation for the extraction of the crystalline lens has been brought to great perfection. Whereas in former times it was considered a hazardous undertaking, it is now known to be one of the most harmless of all operations involving puncture of the walls of the globe. The operation I have done is precisely such as I do in many instances where the extraction of an opaque lens is done to restore sight in an eye previously blind. The chief danger in extracting the lenses from the eyes of persons in good health is in the liability to rupture the hyaloid membrane and allow the vitreous humor to escape. The late Mr. J. Z. Lawrence, of London, called attention to the fact that about one-fifth of the vitreous humor may be lost without serious impairment to the sight. Whilst my experience verifies this statement, I am always careful to avoid the loss of any vitreous whatever, and for two years now I have been fortunate enough in all my extractions to lose no vitreous. I feel that this result is in great measure due to the manner in which I open the capsule. I sometimes make the peripheral corneal section, sometimes the old flap, and sometimes the section of Liebreich. In a few instances I have had, after puncturing the eye with the knife, to complete the section with the scissors. I nearly always perform iridectomy before attempting to extract the lens. I sometimes incise the capsule with the point of the knife whilst I am making the corneal section, and I sometimes depend upon peripheral laceration of the capsule after the iridectomy has been completed. I have concluded that it is safest and best to pass the knife through the cornea on to the area of the pupil, then impale the capsule of the lens, pass the knife, on making the counter-puncture in the cornea, and at the same time dividing the capsule. Having previously dilated the pupil with atropia, this manœuvre frequently enables me to extract the lens without the necessity of removing any portion of the iris whatever. I have some magnificent results from this practice. If the iris does not flow quite out of the wound, there is no necessity whatever in the great majority of instances for the performance of iridectomy, and even in some cases where the iris flows out, if the lens escapes readily from its capsule, the cortical substance may be removed, the iris returned with a small spatula, the pupil contracting readily, and the corneal wound unites by primary adhesion, giving thus a perfect result in all respects. It is frequently necessary after an operation of this kind, when the eye has fully recovered, to perform a secondary operation, lacerating with needles the posterior capsule of the lens. It often happens that in

an eye which recovers promptly from such an extraction as has just been described, and which has apparently a perfectly clear pupil, the slightly opaque posterior capsular membrane offers sufficient obstruction to the entrance of light to interfere greatly with the acuity of vision. In such cases laceration of the posterior capsule is effected by the introduction of two needles through the corneal substance from opposite sides, impaling the opaque capsule upon the point of one, whilst the other needle is passed in close by the point of entrance of the first into the capsule. Using the walls of the cornea as a fulcrum, one of the needles is made to sweep around the other in such a way as to insure a wide laceration of the opaque membrane. As soon as it has been determined that the laceration is sufficiently large, the needles are withdrawn, the eye closed for a few minutes, and a drop of atropia instilled. In twenty-four hours it usually happens that the effects of this operation have disappeared. When the eye is no longer irritated, the adaptation of glasses usually gives a satisfactory result. So you see now that extraction of cataract, though a much more complicated operation than the old method of couching, yields far more satisfactory results. In fact, I consider extraction of cataract about as uniformly successful as the amputation of fingers, comparing the proportion of eyes lost from the one with the number of deaths by tetanus from the other.

TRANSLATIONS.

PILOCARPIN IN DIPHTHERIA.—Dr. Neumeister has just published (*Deutsche Med. Wochens.*, 1881, p. 95) the account of his carefully conducted experiments upon the employment of pilocarpin in diphtheritis. Twenty-eight patients were treated with pilocarpin in the Lazarus Hospital. Of these, five were adults, the rest children. The type of disease was severe. The patients were carefully watched, received nourishing diet and stimulants, and the adults took two to four milligrammes ($\frac{1}{30}$ —$\frac{1}{16}$ grain) pilocarpin every hour or oftener, day and night, while the children took $\frac{1}{60}$ —$\frac{1}{25}$ grain in the same way. The adults became salivated more frequently and more easily than the children, in one of whom, a strong boy, the medicine given day and night for ten days failed to excite the least symptoms of salivation. This failure in some cases and excessive salivation in others is attributable to personal idiosyncrasy. Where there were concomitant symptoms of scarlatina the absence of salivation was particularly noticeable.

In considering the influence of pilocarpin upon the course of the disease, Dr. Neumeister separates the adult cases from those of children. With regard to the latter, in no case could any favorable influence of pilocarpin on the course of the affection be observed. Even where salivation was produced, the disease ran its course apparently unchanged. There was no fall of temperature and no loosening of the false membrane, the diphtheritic process spreading continuously in the mucous membrane. In four of the twenty-three children tracheotomy was performed. Thirteen died. In eight cases the bad effects of pilocarpin were observed. In one case, after long use of the pilocarpin, albuminuria appeared. In six cases sudden failure and irregularity in the pulse supervened. In adults the influence of pilocarpin appeared, on the whole, favorable. Four recovered in a relatively short time: of these, three were salivated, with a rapid fall of temperature and marked general improvement in feeling.

Neumeister, therefore, upon the whole condemns the employment of pilocarpin in the diphtheritis of children: 1, because it is insufficient to excite salivation; 2, because, even when salivation has been induced, the false membrane is not loosened. "Why, indeed, should this occur?" asks Neumeister. "How should the excitation of the salivary secretion affect a process which is often so deep as to involve necrosis of the mucous membrane?" 3. Pilocarpin is to be condemned because in children it is a dangerous remedy, which, even in small doses, may give rise to weakness of the heart and threatening collapse.

PATHOGENESIS OF BLENNORRHAGIC EPIDIDYMITIS.—At a recent meeting of the Société de Chirurgie (*La France Méd.*, 1881, p. 245) Dr. Despres said that Ricord had studied this affection most thoroughly, his views having appeared in a communication to the Académie de Médecine, and in his annotations to Hunter's work. Despres himself thinks that the theory of propagation of the inflammation is not satisfactory. Suppuration of the surface does not descend to the epididymis. Epididymitis

itself does not present the appearance of a suppurative inflammation. In autopsies dilatation of the seminiferous ducts and retained spermatic fluid is observed. The patients have had orchitis at a period anterior to that at which the inflammation could have been propagated. Epididymitis shows itself not later than at the end of a fortnight. The spermatic fluid is secreted constantly, even during the severest and most protracted diseases. Blennorrhagic epididymitis occurs in patients in the vigor of life. The reason for this is that when blennorrhagia begins, coitus ceases; the testicles become painful; towards the sixteenth to the twentieth day the patient has an orchitis, especially if he goes about or is employed in heavy labor. Epididymitis, then, is in reality brought about by retention of spermatic fluid in the testicles when joined to this is some exterior cause of testicular engorgement. Why are not both testicles affected? Because, as the cause itself of epididymitis is only occasionally operative, so this cause usually manifests itself unilaterally. In some patients epididymitis develops after coitus, or after a nocturnal pollution; this is because after this the testicle functionates the more only to fill the seminal vesicles anew. Epididymitis may occur after blennorrhagia, catheterization, arrest of a stone near the ejaculatory ducts, fistula in ano, ablation of hemorrhoids, cancer of the rectum, because in each case compression is made on the ejaculatory canal. It is difficult to explain the affection by propagation of inflammation, but easy to explain it by compression of the ducts.

Therapeutics of Headache.—Massini (*Deutsche Med. Wochens.*, 1881, p. 101; from *Correspondenz-Blatt f. Schweitz. Arzt.*) recommends bromide of potassium, particularly in uræmic headache. Ergotin is useful in paralytic conditions, nitrite of amyl in spasm. Then follow quinine, caffein; but all these medicines fail sooner or later, and then recourse is had to narcotics. There is always fear, however, of morphiomania. Recently, croton chloral, in doses of five to eight grains every three hours until thirty grains have been taken, has been recommended in uræmic headache. Monobromide of camphor in gelatin capsules, in doses of three-fourths of a grain to six grains (in gastralgic forms), is also of use. Aconitia (the English preparation) in doses of $\frac{1}{60}$ to $\frac{1}{30}$ grain is highly recommended by Massini, who also suggests that the effect of these remedies may be increased by the external employment of ointments of aconitia and opium. Tincture of gelseminum in thirty- to sixty-drop doses in neuralgia of the fifth pair is, in Massini's opinion, an excellent remedy. [He fails to add the caution that this remedy sometimes produces very unexpected toxic results, and is altogether very much like a boomerang in the hands of the inexperienced. The weapon may be launched against the disease, but may easily miss that and hit the patient.—Ed.]

Final Result in the Radical Operation for Hernia.—H. Braun (*Cbl. f. Chir.*, 1881, p. 122; from *Berlin. Klin. Wochens.*) gives nineteen cases of hernia treated by the radical operation under antiseptic precautions. Eleven cases were unilateral, three bilateral inguinal hernia; two cases omental hernia through the linea alba. The operation was undertaken six times after herniotomy for strangulation, nine times because the hernia could not be kept in position by a truss, twice in irreducible hernia, and twice because of intestinal fistulæ in the hernial sac. In one of the latter cases, cœcal hernia, there was no hernial sac. Two of the cases operated upon died: one, an adult, died of pyæmia. The other was a six-months' child, who died of convulsions a few days after the operation. The final result in the other operations varied according to the age of the patient. While in the case of the children a permanent cure resulted, in the adults, on the other hand (excepting the two cases of omental hernia of the linea alba), a radical cure was not attained in any case. A relapse occurred invariably after the lapse of a year, or at most two. Braun says the operation is only justifiable—1, after herniotomy; 2, in very large or irreducible hernia; 3, when fecal fistula into the hernial sac exists. In small, free hernia the operation is contra-indicated.

The Employment of Hypodermic Injections of Extract of Ergot in Varicose Ulcers and Eczema of the Leg.—The difficulty of curing varicose ulcers and eczema of the leg in connection with the varicose condition is well known, as is also the frequency of relapse in these cases, which it seems at times almost impossible to guard against. After long patience on the part of physician and patient, after rest and bandages and dressings, at last a

cure is attained, but the blue and swollen veins and the unhealthy-looking integument promise poorly for the future. Sooner or later a relapse is almost sure to occur.

With the view of obviating this, Dr. Meyerhoff (*Deutsche Med. Wochens.*, 1881, p. 96) has employed the following procedure. The ulcer being dressed with a two per cent. carbolic acid lotion, subcutaneous injections of extract of ergot were made in the deep plexus of veins around the ulcer, one every second or third day, about a grain and a half being injected each time. After the injection the limb was enveloped in a flannel bandage, and the patient reposed during that day. Nine cases were thus operated upon, the average number of injections required to heal the ulcer in each case numbering about eight, with two or three given subsequently to make all sure. The narrowing of the vessels was very decided. Relapses did not take place. The operation causes pain, lasting six or eight hours, but no abscess.

Malignant Pustule successfully treated by Injections of Carbolic Acid.—At a recent meeting of the Académie de Médecine (*Le Progrès Médical*, 1881, p. 143) Dr. Trélat told of a woman of 25, who had been stung by a fly, and who presented very grave symptoms when admitted to the hospital. Extreme anxiety, sighing respiration, intense fever, and weakness were present. Over the upper third of the sterno-mastoid was a characteristic elevation with a black centre, surrounded by a peripheral zone, on which were seated vesicles. Beyond this the skin was red and tumefied, the color spreading over the neck and even to the bosom. The diagnosis of malignant pustule being beyond question, Dr. Trélat made a deep incision through the slough and applied Vienna paste, after which he made four injections of twenty-per-cent. carbolic acid in the vesicular zone. The next day there was some improvement: the number of injections was increased to ten, and the improvement continued; the injections were then reduced by two daily, carbolic acid being given internally. Eight days later all the alarming symptoms had disappeared and the patient was practically well.

Globose Vegetations of the Heart.—Dr. Maurice Letulle (*Le Progrès Médical*, 1881, p. 145) gives the case of a woman of 65, who, in addition to evidences of embarrassed circulation, suffered extreme pain on the least pressure in the intercostal spaces of the cardiac region. The diagnosis made was dilatation of the heart, probably secondary to a mitral lesion. The patient dying shortly after, the autopsy showed the heart much hypertrophied, dilated, and filled with clots. The left ventricle contained a score of globulated vegetations within its cavity, and for the most part inserted near the apex. These grayish masses, of which the free surface in the ventricular cavity was smooth and regular, were roundish or ovoid in shape, and adhered closely to the endocardium; the largest was the size of a nut. Similar growths, in smaller numbers, were found in the right auricle. Incisions into the myocardium showed marked alterations, with incipient aneurisms of the heart. According to Letulle, these vegetations represented a spontaneous arterial thrombosis developing itself in the neighborhood of vascular localities invaded by arteriïtis.

Tripoli instead of Plaster of Paris in Bandages.—Dr. Von Langenbeck (*Cbl. f. Chir.*, 1881, No. 6; from *Berliner Klin. Wochens.*) recommends tripoli instead of plaster of Paris for the immobile bandage. Tripoli is a gray, finely-powdered mass, the method of manufacture of which is kept secret, but which is known to include lime and silica as its chief constituents. Tripoli bandages are applied in the same way as plaster-of-Paris bandages. Its advantages over the latter are the following: it absorbs moisture from the atmosphere with greater facility; it is lighter; it hardens faster, and when once set takes up no more water, so that, if penetration of water under the bandage is prevented by rubber cloth, the patient can be bathed without difficulty. In addition, tripoli is cheaper than plaster of Paris.

Hereditary Ichthyosis Cornea of the Palm and Sole.—A. Thost (*Inaug. Diss., Heidelberg*, 1880; *Cbl. f. Chir.*, No. 10, 1881) tells of a family in which ichthyosis was handed down for four generations. According to the ascertained genealogy, the ancestor who was first known to have suffered from this affection had five male children who inherited it, while one boy and one girl were spared. One of these diseased children himself begat five children, of whom three males showed the disease, while one boy and one

girl remained free. Another brother of the second generation begat five male and three female children; of these, four boys and two girls became affected. One of these latter (of the third generation) bore four children, of which three girls inherited the disease, while the fourth, a boy, escaped. Of these seventeen cases, eight were seen by Thost and careful notes were taken. It appeared that the affection always showed itself within a few weeks after birth in the form of a roughness of the palmar and plantar surfaces. With the growth of the child the condition constantly increased in severity, the epidermis shedding in large shreds until the disease reached its maximum by the fourteenth year. There was a marked disposition to excessive sweating, particularly in the diseased localities; the sensibility of the skin remained normal. Microscopic examination showed, in addition to the hypertrophied papillæ, great development of the sweat-glands, with marked thickening of the ducts. All kinds of treatment failed to give more than partial relief.

Sugar of Milk as a Medicine.—Dr. Moritz Traube (*Deutsche Med. Wochens.*, 1881, p. 113), believing that the laxative effect of whey is not, as is generally supposed, due to the salts contained, but to be attributed to the milk-sugar, was led to make certain experiments to ascertain the facts in the case. Having suffered for several years from constipation, he experimented upon himself as follows. About half an ounce of very finely powdered sugar of milk was dissolved in half a pint of yet warm boiled skim-milk, and the faintly-sweet solution drunk in the morning upon an empty stomach. An hour and a half later breakfast was taken, and in two to three hours after drinking the mixture a full, loose, brown stool was passed without discomfort. Traube has employed this mild laxative almost daily during the past fifteen months, using milk diluted with an equal bulk of water. The effect has always been satisfactory, and he has not been obliged to increase the dose of sugar of milk. Traube has employed milk-sugar in other persons, and usually, but not invariably, with success. Where it failed, he is inclined to attribute its want of success to the small dose employed or to the peculiar constitution of the patient. Regarding the amount of milk-sugar which can be taken without injury, Traube has used as much as six drachms in half a pint of water without ill effect.

A Lump of Shellac as a Cause of Ileus.—Friedländer (*Cbl. f. Chir.*, No. 10, 1881; from *Berlin. Klin. Wochens.*) found, at the post-mortem examination of a middle-aged cabinet-maker who had died with symptoms of ileus, a hard concretion, which was situated in the small intestine, thirty centimetres above the ileo-cœcal valve, and which completely filled the lumen of the intestinal tube. Numerous smaller masses, of a similar character, were found higher up in the intestine, which altogether weighed nine hundred and sixty grammes. These masses consisted of shellac, and an examination into the late patient's history showed that he had been what is called a "polish-soaker," —that is to say, he had been accustomed to drinking the polishing-fluid made use of by cabinet-makers, and which consists of a solution of shellac in alcohol. The alcohol had been absorbed in the stomach, while the shellac had been thrown down and had gradually concreted.

It is said that among the cabinet-makers' apprentices of Berlin there are many "polish-soakers," and Friedländer suggests that possibly the mysterious concretions found by Langenbuch, and which were reported at the recent congress of German surgeons, might have had a similar origin.

A New Symptom of Scrofula.—Dr. Constantin Paul has directed attention to what he considers a valuable sign of scrofula (*Bull. Gén. de Thérap.*, vol. i., 1881, p. 137). During the past two years he has observed no fewer than twenty-five cases of lupus originating in the lobe of the ear as a result of piercing for ear-rings. The affection shows itself in a multiple division of the lobe, the ear-ring working its way out and a new puncture being made, followed by the same process.

Abscess of the Brain in a Fœtus.—Dr. R. H. Bakewell (*Lancet*, vol. i., 1881, p. 142), in the case of a fœtus born after having been dead probably about ten days, found the skull collapsed, with a third of its usual contents; the bones were all loose, and several completely detached from their articulations. They were denuded of pericranium. The skull-cavity was filled with blood and pus. But little brain-tissue could be detected, and that appeared to consist entirely of the convolutions. The placenta was small, and had numerous hard fibroid masses in it.

MEDICAL TIMES.

PHILADELPHIA, APRIL 23, 1881.

EDITORIAL.

DR. ISAAC RAY.

ISAAC RAY, M.D., LL.D., one of the most distinguished and best known of American physicians and writers, died at his residence, on Baring Street, in the city of Philadelphia, on the 31st of March, 1881, in the seventy-fifth year of his age.

Dr. Ray was a native of Massachusetts, and was born in the town of Beverly on the 16th of January, 1807. He commenced his literary education at Phillips Academy, in Andover, and afterwards entered Bowdoin College, where he prosecuted his studies till 1824, when he was compelled to leave on account of ill health. While at college, during the vacations he taught school, and was noted for his ability in an occupation in which so many of the great men of this country have been engaged in the beginning of their careers. Soon after leaving college, when his health had sufficiently improved, he commenced the study of medicine, passing a portion of the time in the office of Dr. Shattuck, a distinguished physician of Boston, and graduated at the medical department of Harvard University in 1827.

Dr. Ray began the practice of his profession in the city of Portland, Maine, in 1827, and he here met and married, in 1831, Miss Abigail May Frothingham, a most estimable lady, who still survives him, and with whom he lived in mutual confidence and happiness to within exactly two months of a period of fifty years.

Two years after commencing practice in Portland, inducements were offered to him to remove to Eastport, in the same State, in which place he soon afterwards fixed his residence. It was in Eastport that Dr. Ray's attention was first directed to the subject of insanity, and while there he wrote and published the first edition of his work on "The Jurisprudence of Insanity," of which six editions are now exhausted. This work is known everywhere where the English language is spoken, and is universally regarded as a high authority, no less by the members of the bar than by alienists and all the medical profession.

In 1841 Dr. Ray was appointed Medical Superintendent of the Maine Hospital for the Insane at Augusta, which position he held till he was invited by the authorities of the Butler Hospital at Providence, Rhode Island, to become superintendent of that institution—which was just then being organized—and to supervise its erection. While a resident of Maine, and especially while in connection with its State institution for the insane, he had abundant opportunity to observe the unfortunate results which have so often arisen in various parts of our country from such institutions being under political management or controlled by bodies of men whose personal interests in their affairs led to the sacrifice of officers of the highest capacity and integrity simply because they could not be induced to become agents for carrying out any plans that were not for the best interests of the institutions and their patients. On all such points Dr. Ray's opinions were most emphatic, and no one has done more to secure the proper organization of American hospitals for the insane.

Dr. Ray was led to accept the position offered him at Providence especially from the fact that that hospital was to be the offspring of private munificence, and was to be controlled by men who were above all suspicion of political or selfish interest in reference to it. Beyond this, he was here offered an opportunity to introduce into the construction of the buildings and into the subsequent management of the

institution his well-matured views on all these subjects.

After a visit to a number of the prominent institutions for the insane in Great Britain and on the continent of Europe, Dr. Ray returned to the United States and personally superintended the completion of the Butler Hospital, which he opened for the reception of patients in 1847. He continued to fill the office of superintendent of that institution till January, 1867, when, to the great regret of the authorities of the hospital and of all in any way interested in its welfare, he felt impelled, by a conviction that his health required a change of climate and occupation, to resign the position which he had held so acceptably to all, and with such signal advantage to the afflicted, for a period of more than twenty-two years.

For the first time in his life, with the exception of his short European trip, he was now released from labor, and spent the greater part of a year in visiting his professional brethren, and in seeking a place for his future home, finally adopting the city of Philadelphia, in which he settled permanently in 1867.

This release from the cares and responsibilities that are inseparable from a conscientious performance of the duties of a superintendent of a hospital for the insane, with the change to a milder climate, was greatly enjoyed by Dr. Ray, and seemed to have a very beneficial influence on his health, so that, from being unable to go more than a few blocks from his house on foot, he now extended his walks to four or five miles daily. All these changes gave him opportunity for the literary labor in which he so much delighted, and for complying with the frequent calls that were made upon him for professional consultations and for his opinions as an expert in criminal cases and in regard to the mental capacity of individuals who were making testamentary disposition of their property.

Dr. Ray was one of "the original thirteen" who in 1844 established "The Association of Medical Superintendents of American Institutions for the Insane," and also took a deep interest in its success. He was rarely absent from its meetings, was a frequent contributor of valuable papers, and participated actively in nearly every discussion coming under its notice. He was its president from 1855 to 1859. At the meeting of this association in Providence, in 1879, he was the recipient of distinguished attentions from his old associates, friends, and neighbors, as well as from the Rhode Island Medical Society (of which he was at one time president), and from Brown University, which at this time conferred upon him the honorary degree of Doctor of Laws.

Dr. Ray was a Fellow of the College of Physicians of Philadelphia, frequently read valuable papers at its meetings, and always took an active interest in matters coming up for discussion.

He was a most industrious writer. Besides his well-known larger works, there were few matters of professional or public interest that did not to a greater or less extent, through the various journals or in the daily public press, receive the benefit of his clear views and wise suggestions.

The death of such a man as Dr. Isaac Ray—a wise counsellor in all cases of obscure mental disturbance—makes vacant a place in this community, in the medical profession, and in the specialty to which he particularly devoted himself, that cannot readily be filled. By those who knew him intimately, in addition to this, there must be felt the sundering of the social ties of friendship and tender regard, the loss of his genial presence, his words of wisdom, and his remarkable and variable conversational powers, which made him interesting alike to the gravest men and to the prattling children with whom he was always a favorite.

After impressive funeral services in the

chapel of the institution, where every mark of respect was paid to his memory, the remains of Dr. Ray were interred in the cemetery adjoining the grounds of the Butler Hospital, at Providence, which he loved so well, and in which he had spent so long a portion of his active and useful life.

CLINICAL INSTRUCTION.

MOST of our readers have, no doubt, read more or less of the discussion which has been carried on with sufficient acrimony between the *London Lancet*, Professor Gross, and the *New York Medical Record*, or, perhaps to speak more accurately, between Mr. A. E. Broster and Professor Gross in the two journals named, the editors aiding, abetting, stimulating, by comments, much as the sponge-holders stimulate combatants in a less honorable cause. The tone of the last editorial in the New York journal is notable. Our most honored colleague writes as though his life had been spent among the deserts of Africa, or in some high court of Europe where no western breeze ever wafts democratic news to aristocratic ears. According to the veracious chronicles of Atkinson, for five-and-forty years has he lived in and about New York City, save when travelling up and down the land in the service of his country; for many years editor of what, if we take it at its own valuation, is the "livest" journal in America. Sitting, therefore, in an editorial sanctum as a spider sits in the centre of a web which reaches everywhere, he confesses to a little curiosity in learning of the actual facts in the controversy! Does he not know them? Is No. 27 Great Jones Street, New York, such a distinct recess of the American continent that neither telegraph, mail-bag, nor messenger from other parts of the United States can reach it? Possibly! Or is our most honored friend a little afraid or a little ashamed to tell the truth in regard to the average medical teaching of America? The truth, properly stated, might be written in very brief terms, but the mass would be as bitter as a pellet of strychnia, and represent much more of destructiveness to human life.

In most of our medical colleges there is no roll-call. No personal efforts are made to see how much instruction of any kind the student receives, and there is no necessary personal contact between him and any official teacher. A class, it may be, of six or seven hundred men—some fresh from the country, some nearly ripe for graduation—are lectured to by the professor at stated times: it is plainly impossible for the speaker to know more than a fraction of his hearers. Clinical teaching is upon the same basis as other teaching: the clinical lectures are given; the student can come or go, as he chooses. Theoretically it may be possible for a man to graduate without seeing a single case, just as theoretically it is possible for him to graduate with a very slight attendance on teaching of any kind. Practically the students attend the clinics as well as or even better than they do the didactic lectures.

The criticism of Mr. A. E. Broster is theoretically right, practically wrong. His prying finger does not touch the real sore in most American clinical teaching, —namely, that it is, for practical purposes, little or no better than didactic lectures. A huge class on the benches, a sick man in the amphitheatre, employed by a brilliant lecturer as a text for a discourse,—this is ordinary American clinical teaching; and it is not only possible for a man to graduate in an American college without having been taught practically the difference between a sibilant and a mucous râle, but a large proportion of the men who do graduate know nothing about any form of physical diagnosis, and those who have learned the art have done so from private sources and of their own free

will, not because they have had opportunities offered, and not because they have any fear of being expected by examiners to have any practical knowledge of the subject.

The New York colleges, the Jefferson Medical College, the Eastern and the Western schools in general, are at one in these respects, except only those schools which have reformed their programme of teaching,—namely, Harvard University, the University of Pennsylvania, the Michigan University, and a few of the smaller institutions. In these—all, we believe, certainly in the two we know most about—at the bedside clinical medicine is taught thoroughly to small classes, and attendance upon such instruction is enforced upon the student.

NO PREMIUM ON FOLLY.

NOT long ago an American physician lost his life from diphtheria contracted in the attempt to clear a tracheotomy-tube by sucking it. His act of folly was, in the opinion of some, hardly condoned by its punishment; by others it was lauded as an act of heroism. A recent number of a contemporary relates with satisfaction that the Albert Medal has been conferred upon a young surgeon of England—a Mr. Grier—who applied his mouth to the tube to restore respiration in a similar case. The editor of our contemporary makes this the occasion for some ironical remarks about the want of appreciation of such deeds in "the land of the free and the home of the brave."

It is a pity, not that there should be this lack of appreciation, but that there should be any exception to it. It is time, indeed, that expressions of admiration for reckless and unthinking acts of folly should stop, and that men who have any influence in moulding public sentiment should strengthen the opinion that it is not praiseworthy, but on the contrary censurable, for one to expose a valuable life in the hope of saving one of less value, and tenfold reprehensible when the risk is so enormous and the benefits are so unlikely to be obtained or kept as in the cases we have just referred to. The man who does such things is not brave, he is rash; and, hard as it may sound, the American who lost his life and the Englishman who received the Albert Medal were both actuated by idiotic although courageous impulsiveness.

If the commander of the charge at Balaklava had survived only to be court-martialled and shot, we might have lost a very effective occasion of school-boy oratory, but we would also have been spared a very pernicious example of praising what should be universally condemned. The same principle should guide us in expressing opinions of men who try to clear tracheotomy-tubes with their mouths. If they die in consequence, natural etiology takes their punishment out of our hands; if they live, they should be pilloried as a warning to others.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, JANUARY 27, 1881.

THE PRESIDENT, Dr. S. W. GROSS, in the chair.

Acute caseous phthisis. Exhibited by Dr. J. H. MUSSER.

WHEN removed from the body, the lungs which are before you this evening presented the following appearances. *Right* lung: costal and pulmonary pleura adherent; entire lung consolidated. On section, upper lobe of a yellow color, very soft, cheesy, presenting numerous small cavities, from which poured a thick gray fluid. A strong stream of water playing on the lobe washed out the soft cheesy material and revealed the lung riddled with cavities not larger than a filbert, generally communicating. The middle lobe was completely consolidated, of a gray color, very slightly granular, and exuded a thin fluid. The lower lobe was grayish-yellow, soft, with three small cavities. *Left* lung: pleural adhesions at apex; one-fourth of the upper lobe presented the characteristic ap-

pearances of catarrhal pneumonia. The remaining organs were normal.

The specimens were removed from a young man 25 years of age; single; a painter; of good habits; without any hereditary predisposition to disease. He had always enjoyed good health, and had never been subject to cold. One month prior to admission to the hospital he caught "cold." Persistent cough was the only symptom for two weeks. Then he noticed feverishness and night-sweats. The cough, at first dry, about the same time became muco-purulent. Emaciation and loss of strength followed. His appetite remained very good, and there was no gastro-intestinal derangement. During this time and until admission to the hospital he was going about from place to place in the Eastern States in search of work. The past week the fever and sweats and the cough have continued, the emaciation has progressed, and the debility has become greater.

On admission, November 5, haggard and emaciated; dry hot skin throughout the day; exhaustive night-sweats; face pale; hectic flush; eyes blue; sclerotics pearly; hair brown; lips thin and pale; hands bluish; fingers not clubbed; special senses and cerebral faculties normal; teeth poor; tongue red, clean; appetite and digestion very good; no diarrhœa; liver and spleen normal; pulse 110; heart-sounds normal; respirations 28; almost constant cough, worse at night; abundant muco-purulent expectoration; great pain in right side and at right apex, with tenderness; unable to lie on that side. Physical signs of consolidation of right upper lobe, anteriorly and posteriorly, with mucous râles.

November 17. — The severe cough has continued; extreme pain; fever and profuse sweats; emaciation progressing; weak. The dulness, the bronchial breathing, and bronchophony of the right apex have been replaced by cracked-pot sound, amphoric breathing, and pectoriloquy. These signs are especially distinct between the clavicle and the third rib. Consolidation of the middle lobe is noted, and partially of the lower.

November 21.—The physical signs of a cavity noted last week continue, but are variable. At one time cracked-pot sound is absent and tympany present, cavernous breathing replacing the amphoric. With amphoric breathing there are a few large râles; when cavernous, innumerable moist râles are heard. The more distinct evidences of consolidation of the lower lobe were frequently pronounced, with dulness, bronchial breathing, and subcrepitant râles. No alteration of digestion; pain and cough only relieved by morphia; fever and sweats continued; breathing hurried.

November 21.—The distinct but variable pectoriloquy and other signs of a cavity continue. At the base complete consolidation and softening; large mucous râles heard all over the chest. Impaired resonance and prolonged expiration, with a few crackling râles, noted three days ago at left apex; they continue.

On November 30 the following physical signs were noted. Thorax long and flat; considerable flattening above and below right clavicle; expansion impaired; vocal fremitus increased over lung anteriorly, diminished at base posteriorly. On light percussion, in first interspace at right edge of sternum, tympany becoming dull towards shoulder; on deep percussion, cracked-pot sound. In second, on light percussion, tympany especially on full inspiration; at end of expiration, dulness; on deep, cracked-pot sound. From the third rib to the liver, vesiculo-tympanitic percussion-note. On auscultation, cavernous breathing of high pitch, becoming amphoric towards the shoulder, with large bubbling râles in the first interspace. In second, cavernous breathing and bubbling râles; from third rib, cavernous breathing and mucous râles. Pectoriloquy absent to-day, though at times distinct in the three upper interspaces; vocal resonance absent. In line of axilla, dulness from above downwards. Posteriorly, dulness to middle of scapula, increased resonance below. Where dulness, vocal fremitus increased, absent where extra-resonant. Above spine of scapula, amphoric breathing and bubbling râles; from spine to middle of scapula, blowing, almost cavernous breathing, with moist crackling râles, in inspiration, and only the râles in expiration. Below middle of scapula numerous moist râles and a very faint blowing breathing. Left apex as previously noted.

Hectic very great; delirium at night; muco-purulent expectoration, slightly streaked with blood; daily epistaxis; tongue clean and red; bowels costive; appetite good.

December 6. — Cracked-pot sound from clavicle to fifth rib on right side, in first interspace on left; other signs the same; continual low delirium and stupor.

December 16.—No noteworthy change in physical signs. Died of exhaustion to-day.

Note first the pathological conditions of the lungs. Upper lobe, numerous cavities; middle lobe, consolidation; lower lobe, consolidation, caseation, a few cavities. Note that over the upper lobe anteriorly there was tympany or cracked-pot sound, cavernous or amphoric breathing, variable pectoriloquy; posteriorly, dulness and amphoric breathing; physical condition, innumerable small cavities. Over middle lobe, vesiculo-tympanitic note and cavernous breathing in front, dulness and blowing breathing behind; lobe consolidated. The lower lobe completely consolidated, with a few cavities yielding vesiculo-tympanitic percussion-note all over; cavernous breathing anteriorly, faintly blowing posteriorly. The intermittency of the pectoriloquy and the variability of the auscultatory and percussion phenomena are of interest.

There was no mistake in the above signs, as they were demonstrated to ward classes, and from time to time compared with the physical signs given by the enormous cavity in the lungs which I presented December 13. I neglected to note, also, that the cavernous or amphoric breathing was often heard clearer in inspiration.

Case of chronic peri- and intra-articular disease of knee-joint. Presented by C. B. NANCREDE, M.D.

Peter ——, æt. 60 years, was admitted, September 13, 1880, to the male surgical ward of the Protestant Episcopal Hospital, suffering from a slight but painful swelling of the left knee-joint. He had been a hard drinker and an inmate of the House of Correction until his transfer to my wards. He could assign no cause for his trouble, but said the other knee had been similarly affected and the disease had been pronounced rheumatic.

The joint steadily increased in size, but did not assume the peculiar form of acute synovitis, the swelling inclining to project more into the popliteal space and externally. By September 21, 1880, free fluctuation was detected, when the purulent collection was aspirated, and proved to be distinctly extra-articular. The puncture soon ulcerated, when an exceedingly profuse discharge ensued, and continued for many weeks. After numerous counter-openings, oakum setons, etc., had been resorted to, the discharge diminished greatly in quantity, but the pain rather increased, until large doses of morphia were necessary to procure any relief. The joint became firmly anchylosed. During the month before operation he had two attacks of agonizing pain in the joint and its neighborhood, which so interfered with sleep and his appetite that he rapidly began to fail and was urgent to have his limb removed.

Accordingly, on January 17, 1881, I amputated the thigh at the junction of the middle and lower thirds, after which he made an unusually rapid recovery.

Upon examination, the tissues surrounding the joint plainly indicated marked disease, while the joint itself was obliterated by adhesions, except over the under surface of the outer condyle, with the corresponding facet on the tibia, and over the patella, with the subjacent portion of the trochlear surface. Here there had been distinct hemorrhages, stretching and distending the adhesions. The inner facet of the patella was slightly eroded. It seems not improbable that the two sudden attacks of pain before referred to were due to the stretching of the adhesions produced by the sudden giving way of blood-vessels pouring out blood into the two small cavities just described.

Dr. GROSS considered that in this case the trouble arose from inflammation of the lamella of bone just beneath the cartilage coating the patella. This is the usual way for joint-trouble to commence, except when the synovial membrane is diseased. He thought that the eroded cartilage was the source of the hemorrhage and the pain, rather than any stretching of adhesions, which he considered impossible by any passive hemorrhages such as these effusions must have been.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting of the Society was held at the hall of the College of Physicians, Philadelphia, January 26, 1881, Dr. Albert H. Smith, President of the Society, in the chair, at which Dr. E. T. Bruen read a paper entitled "Some Observations upon the Carlsbad Treatment," and Prof. H. C. Wood presented a case of nerve-disorder in a man about 40 years of age, presenting some unusual symptoms.

PERIPHERAL NERVOUS PHENOMENA DUE TO INTRATHORACIC GROWTH.

The following history of the case was given. The patient had suffered for many years with epilepsy, but without decided mental derangement. About a year ago he complained of contraction of the "cords in his neck," and at the same time a tumor was observed in the front of his neck which gradually increased in size. Recently he exhibited symptoms of hyperæsthesia in the parts supplied by the brachial plexus, for which he sought treatment: he had not complained of dyspnœa, but the respirations were found to range from 26 to 30.

The tumor of the neck displayed upon his appearance before the Society was connected with the thyroid gland, and moved with the larynx in swallowing: it had the appearance of a cystic thyroid growth. The peculiar symptoms were the hyperæsthesia existing around the shoulder and down the arm; a touch upon the skin gave him excessive pain. In the supra-clavicular fossæ were found some enlarged glands; there was evidence of pressure upon the left bronchus; the upper two ribs were depressed, and the venous murmur was less on the right side of the neck than on the left side.

In seeking for the cause of the symptoms, the speaker said that he believed it must be sought for within the chest, that there must be pressure exerted in the posterior mediastinum, producing irritation of the sympathetic ganglia and disturbance of sensation upon the right side. The left side is not seriously implicated in the pressure-symptoms. The source of pressure must operate unequally upon the two sides; it must be low down below the bifurcation of the trachea, because the respiratory movements of the glottis were normal and there was no laryngeal paralysis. As to the character of the growth, there was no evidence of aneurism, no pulsation, no

bulging near the sternum. He saw a probable explanation of the pressure in the enlargement of the deep bronchial glands (cancerous or otherwise), subsequently giving rise to neuritis extending throughout the region supplied by the brachial plexus.

To sum up: he considered the pressure of obstruction to be indicated by the sinking in of the supra-clavicular space and groove on the right side, the rapid respiration, the immobile ribs, and the delayed venous flow. These must be located below the bifurcation of the trachea in the mediastinum. The nature of the disease he considered problematical, but it was either carcinomatous or sarcomatous in all probability. In the absence of any signs of aneurism, the diagnosis of a tumor seemed necessary.

In reply to a question, he said that he attributed the peculiar position of the patient's head (wry-neck) to muscular spasm from immediate proximity to the inflamed glands. The condition of the thyroid gland could not explain the nervous trouble, since such a result of goitre would be very uncommon. The disease in the neck had existed for years, while the other symptoms were comparatively recent. Pressure upon the nerve-trunks causes pain, shooting down the arm to the hand; indeed, hyperæsthesia is so marked that pressure on any part causes pain extending over the whole affected area.

Prof. Roberts Bartholow inquired whether the previous history of cerebral disorder could not interpret the phenomena presented by the patient. He had had epilepsy and other evidence of cerebral mischief: could there not be intracranial disorder or pressure, occurring more particularly upon one side, which might give rise to the symptoms? He also asked whether the lecturer had taken into account the possibility of cervical pachymeningitis spinalis, as well as that of cerebral disorder.

Dr. Chas. K. Mills inquired what effect this comparatively acute condition had upon the epileptic seizures, and whether the latter were local, general, or unilateral.

Prof. Wood, in concluding the discussion, said that he supposed the patient had had epilepsy for years, but as to the character of the seizures he could not speak, as he had seen the patient for the first time only a week before. He would not claim that a man could have epileptic seizures for forty years without producing some symptoms of mental disease; but such disease was not marked in the present case, and he could not conceive of any condition of the brain which would produce such peculiar unilateral symptoms. Moreover, he could not see any cause for suspecting the existence of pachymeningitis.

THE CARLSBAD TREATMENT.

Dr. Bruen read his paper, "Observations on the Carlsbad Treatment."

Dr. Addinell Hewson said that he had heard Sir Henry Thompson express strongly his belief in the value of the Carlsbad waters. The speaker had then asked what was his opinion of the artificial Carlsbad salts, and had been told that they were of little value: the natural water should be drunk on the spot, with all the hygienic and climatic advantages to assist in its restorative effects.

Dr. Bruen agreed with the last speaker that residence at the springs was a great advantage, not only because of the natural attractions of the place, but because the physician there has more complete control of his patients than at home.

SPECIMENS FROM HIP-JOINT AND THIGH AMPUTATIONS.

Dr. Chas. B. Nancrede presented a specimen consisting of a femur and a portion of the tibia and fibula of the right side, which he had removed by amputation at the hip-joint. The case was one of alveolar osteo-sarcoma of the femur, complicated by spontaneous fracture three months before the operation. The abdominal tourniquet was used, and Esmarch's bandage applied to the limb, so that no blood was lost except that contained in the flaps. It is probable that these precautions prevented the development of any degree of shock; for no marked depression was observed; the temperature was not over 101°, nor the pulse over 108; on this morning—forty-eight hours after the operation—the temperature was only 98°, the pulse was only 102, and the patient said that he felt very well.

A specimen of the knee-joint, which he also exhibited, was interesting from the explanation of the intense pain from which the patient suffered. The man had been treated for rheumatic inflammation of his right knee; subsequently a swelling developed in the popliteal space, fluctuation became marked, aspiration was resorted to, and sinuses were formed around the joint; but there seemed to be nothing to account for three attacks of intense pain occurring at intervals of some weeks. Amputation was performed, and it was discovered that the patella was slightly eroded, and that there was complete obliteration of the joint by adhesions, except under one facet of the patella and a portion of the outer condyle of the femur. The resulting cavities contained blood. The question arises, may not the separation of the adhesions by this effusion probably account for the attacks of pain? He thought that hemorrhage, to the extent found in this case, occurring in old adhesions in a joint, must be a rare condition. There was apparently very little active joint-trouble; but the exhaustion produced by the pain required operative interference.

THE PRESENT EPIDEMIC OF SMALLPOX.

Dr. M. O'Hara, referring to the epidemic of smallpox which had lasted throughout the winter, said that in two cases which he had

seen the hemorrhagic form bore a strong resemblance to scarlatina. He had not found the hemorrhagic cases to last long, not over the second or third day of the eruption, and on this account he did not consider them so contagious as the others which took the full period to ripen. He had not been able to trace any transmission from this variety in his own cases. He had some doubt in regard to the pathology of these hemorrhagic cases, whether or not the blood-disorder might not have been the primary affection connected with other causes and only started up by comparatively small amounts of the smallpox poison. He called upon Dr. Welch for information in regard to the epidemic.

Dr. Wm. M. Welch said that quite a large number of smallpox cases were being received at the Municipal Hospital, indicating that the disease was quite prevalent, as indeed it had been for several months past. In November, 1879, the disease reappeared in this city after an absence of about two years; the cases steadily increased during the whole of the winter of 1879–80, but they were not, however, very numerous; the number increased during the spring, but diminished during the warm weather of summer. In August they again rapidly increased, so that he doubted whether in the history of smallpox in Philadelphia there had ever occurred before in the month of August as many cases of the disease. During the fall and winter months the disease kept on increasing; and he believed that January would show a larger number of cases than December.

In regard to the hemorrhagic cases he had observed that they usually die during the first week of the eruption. The very malignant cases sometimes die at the beginning of the attack, before the eruption appears. There has been during the present epidemic a large number of hemorrhagic cases admitted into the hospital, though not quite so large a proportion as in 1871–72, and they do not prove so rapidly fatal, many of them living until the beginning of the second week. As regards contagion, he had no doubt that all cases of smallpox, whether hemorrhagic or not, are contagious. In hemorrhagic smallpox the vesicles usually contain blood, or blood mixed with serum, and this gives to the skin a peculiar livid, dark-purple, or indigo color. The conjunctivæ also become infiltrated with blood, the face smooth and glossy, hemorrhage occurs from the mouth and nose, and a little later blood appears in the urine, and frequently in the stools.

Dr. W. R. D. Blackwood said that he had noticed some points in regard to the present epidemic. In looking over his notes, he found that in the previous epidemic (1871) he had seen fifty-seven cases, in which there was only one instance of the hemorrhagic form, which died on the seventh day of the eruption.

In speaking of the portage of the disease, or its spread from the sick to the healthy through an intermediate person not himself affected, he said that the disease had been thus communicated by attendants upon the sick, and he therefore had been especially careful not to see any smallpox cases until he had seen all his ordinary patients. He put off all such cases until the afternoon, and he had gone to a great deal of trouble in changing his clothes before visiting the contagious disease, and subsequently taking a bath and again changing his clothing before seeing his family or attending to other patients. He inquired as to the liability of physicians to carry smallpox or other contagious diseases: as the exposure is only for a short time, he believed that the danger had been much overrated.

Dr. L. K. Baldwin spoke of a case of hemorrhagic smallpox in which, after symptoms of "a cold" had existed for about a week, the eruption appeared on Saturday and the patient died on Tuesday. Both the mother and daughter had subsequently a slight attack of so-called varioloid. When the eruption appeared in the first case it was like purpura. The next day the entire surface was covered with livid patches, and on the third day he passed bloody urine and all the mucous membranes exuded blood. He died the next day, from exhaustion.

Dr. O'Hara, in referring to vaccination, said that he could not understand the variability and persistency of the disease if vaccination is an efficient protective. If a vaccination will take after a person has had smallpox, or a person could have smallpox after vaccination, he could not feel certain that he was fully protected when called to attend a malignant case of smallpox. At the same time, he would vaccinate everybody, even if they had a few smallpox scars on the face.

Dr. R. B. Burns said that in regard to the portage of contagious diseases by physicians, he had not been aware of any instance in which he had carried smallpox, but he had undoubtedly communicated scarlet fever to his own child. He reported a case where a person not exposed to any contagion, as far as could be ascertained, having been confined to the house for some time, developed hemorrhagic confluent smallpox, and died on the fourth day. He had recently seen a case in which, two weeks before the smallpox appeared, the patient had had an ordinary scarlatinal sore throat, fever, and eruption followed by general desquamation. The occurrence of the smallpox was remarkable as illustrating the occurrence of two blood-poisons in the same subject with such a short interval between.

Dr. Welch, in reply to several questions, said that probably a few cases of smallpox were not reported to the Board of Health; but a physician attending a case renders himself liable to a fine of fifty dollars if he does not report it promptly. In regard to the portage

of disease, he believed that smallpox contagion could be carried in clothing. On this account he always was careful to change his clothing and wash before leaving the hospital. He mentioned an instance where a nurse had carried scarlet fever to a child. In another case a female nurse attending a smallpox patient had visited her daughter, and her daughter's child subsequently took smallpox and died. He believed that many such cases occur: so that it becomes the duty of every physician to observe the greatest care to guard against carrying contagion.

Concerning the coexistence of contagious diseases, he had lately seen a case in which scarlet fever and smallpox ran their course together. A colored child was received into the hospital with a mild attack of smallpox. During the first week of the eruption scarlatina also developed, of which disease the child died after an illness of about two weeks. He had seen scarlet fever following smallpox. In 1872 a child with confluent smallpox was under treatment for four weeks, and during convalescence was attacked by scarlatina, and died three days subsequently. It had not been out of the hospital for a month, nor had there been any cases of that disease in the institution. It is possible that it had previously been exposed to the scarlatina poison and that it had lain dormant during the progress of the smallpox.

In regard to disinfectants, he did not know of any efficient aërial disinfectant: the only means of protection was vaccination. He had unbounded confidence in vaccination as conferring immunity from smallpox. Even after exposure to contagion it is effective, providing it is not too long delayed. It often happens that unprotected persons are sent to the hospital by mistake, suffering with other eruptive diseases, or unvaccinated children are sent with their parents. All such persons are at once vaccinated, and frequently with complete protection. He generally uses humanized virus, but sometimes resorts to the ivory points: in the hospital he much prefers the recent crust. He finds that the bovine virus is less rapid in developing, and is therefore less useful than the humanized after actual exposure has occurred. In such a case, where protection is not perfect, if the areola form before the variola eruption appears, the modifying influence is very evident in the course of the disease; otherwise it does not yield any protection, or at least cannot be depended upon. In 1871–72 very little bovine virus was used, but he had obtained complete protection by means of a crust even many times removed.

Dr. S. G. Skillern endorsed the last speaker's remarks about vaccination. In a family not protected the father was taken with confluent smallpox. The speaker vaccinated the entire family, including six children under fifteen years of age, with the humanized virus, which took very well, and not one of them contracted the disease.

He cited the case of a former member of the Society who had a very sad experience of the portage of the disease: he carried smallpox to his wife. A physician should take especial care not to visit other cases after seeing a smallpox patient without changing his clothing.

Dr. Addinell Hewson, speaking of the protection afforded by humanized virus, said that his father (the late Dr. Thomas T. Hewson) and the late Dr. Otto were the first in Philadelphia to receive a crust direct from Dr. Jenner. This was in 1802, immediately on the excitement concerning the discovery of vaccination. From that date to the time of his death, in 1847, Dr. Thomas T. Hewson not only kept himself provided with good healthy virus, but kept records of every one of his cases, which he made it a rule to see on the third, fifth, seventh, and ninth days, so that he could state whether the process had been perfect or not both as to form and time. Such caution Dr. A. Hewson considered essential for success, and the neglect of it was in his opinion the occasion of reported failures. He recalled an instance of a family, all the members of which had been vaccinated in infancy by his father, where one took smallpox in adult life, and it was found upon examination of Dr. Hewson's records that this was the only one of the family in whom the vaccination had never been perfect. He believed that many persons are under the impression that they are protected who have never been properly vaccinated.

REVIEWS AND BOOK NOTICES.

On the Construction, Organization, and General Arrangements of Hospitals for the Insane; with Some Remarks on Insanity and its Treatment. By Thomas S. Kirkbride, M.D., LL.D., Physician-in-Chief and Superintendent of the Pennsylvania Hospital for the Insane at Philadelphia.

This book is the result of the ripest experience and most mature reflections of the oldest and ablest superintendent of a hospital for the insane in the United States, and can be commended in the heartiest manner to the careful study and candid examination of all who are interested in the care and treatment of the insane, whether as officers of hospitals for that class or those in the community at large who wish to be correctly informed in regard to the true principles of construction of such institutions and their proper management after they have been erected.

A careful study of this book will reveal the serious and numerous blunders in construc-

tion which would-be reformers have been so industriously urging within the last few years, and would also prevent that cheap construction which has been so much lauded, but which is ultimately by far the most expensive. From our observation, the zeal of these gentlemen is in inverse proportion to their knowledge and to their desire to be correctly and thoroughly informed on the subject.

The plans recommended and the particular arrangement of those plans in their interior details have stood the test of time and experience in every section of the country, and have been demonstrated to be the only plans which combine economy of construction, thoroughness of supervision, and the greatest efficiency of management.

The second part of the book, on the organization of hospitals and the treatment to be pursued, should be studied in the most careful and thorough manner by every one who wishes to be wisely and correctly informed in all matters pertaining to the interior management of hospitals for the insane. Though many men have allowed themselves to be carried away with the plausible theories of those whose knowledge is of the most superficial character and who have never spent time enough in a hospital to enable them to master the most rudimentary principles underlying the treatment of the insane, yet we are convinced that the precepts and principles laid down in this book will be found by every man of sound common sense and judgment to be those which can alone successfully guide any one in the proper care and treatment of the insane, and that adherence to any other will be a delusion and a snare and only result in lasting injury to the insane.

J. CURWEN.

COLORADO FOR INVALIDS. By S. EDWARD SOLLY, M.R.C.S. Eng., etc. Pamphlet reprint, pp. 28. Colorado Springs, 1880.

No one can read this pamphlet through without feeling glad that he has done so. So vague are the ideas of physicians in the East as to what are the conditions which should determine the choice of a climate in chronic illness that errors are constantly made, and, as a consequence, both physicians and climate suffer in their reputation. The pamphlet gives information which will tend to save the credit of both.

Dr. Solly first defines what is meant by a change of climate, and then shows how the three essential elements which constitute a climate—the qualities of the atmosphere, the soil, and the intensity of the sun's heat and light—are influenced in Colorado, which represents the mountain climate as distinguished from that of the sea-side. The rarity and dryness of the air, with their consequent effects upon temperature, are the chief peculiarities of such a climate. Dr. Solly then shows how the act of breathing is influenced by such an atmosphere; how morbid processes in the lungs are influenced,—inflammations, with catarrhal and interstitial morbid products, blood-spitting, etc.; and, finally, enumerates the classes of cases which may reasonably be expected to benefit in a Colorado climate, and those which are unfavorably affected. Among the former are cases of phthisis not too far advanced, of asthma, of dyspepsia, and of simple nervous exhaustion without organic nervous disease. Among the latter are cases of valvular disease of the heart, especially with fatty degeneration; liver disease in the full-blooded, acute renal disease, etc.

Dr. Solly's broad principle is, "Send the thin-blooded to Colorado; keep the full-blooded away. Send those on the up-grade of life, and not on the down. In diseases—except in that of the lungs—where there is active change of structure, avoid the too rapid life which this climate causes."

In conclusion, the distinctive features of the principal centres of health-resort—Denver, Colorado Springs, Manitou, Pueblo, and Cañon City—are described.

The pleasing style in which the paper is written makes it very interesting, while the air of candor which pervades it commands also the respect of the reader.

IMPERFECT HEARING AND THE HYGIENE OF THE EAR. By LAURENCE TURNBULL, M.D., Ph.G., Aural Surgeon to the Jefferson Medical College Hospital, etc. Pp. 147. Philadelphia, J. B. Lippincott & Co., 1881.

Dr. Turnbull's little pamphlet on "Tinnitus Aurium," published some years ago, has grown in this the third edition to be quite a good-sized volume, and other matters have been introduced which will make it even more acceptable than the previous editions have been. The brochure is now, in reality, a collection of monographs on various subjects in otology, which will be likely to interest the non-specialist and general reader as well as the aurist.

The book includes well-considered articles on "the limit of perception of musical tones by the human ear;" "tinnitus aurium, and observations on aural or auditory vertigo, with diagnosis and treatment;" "the importance of the treatment of the naso-pharyngeal space, tonsils, and uvula in acute and chronic catarrh of the middle ear;" "artificial perforation of the membrana tympani;" "the mastoid region and its diseases, with illustrative cases;" "the hygiene of the apparatus of hearing, with the prevention of deafness;" "on the method of educating the deaf-mute at home, and on the selection of proper schools for the deaf and dumb;" "a comparison between the audiphone, dentaphone, etc., and the various forms of ear-trumpets." There is, in addition, an "introduction," in which the recent progress of otology is given.

We can most heartily recommend Dr. Turnbull's work to any one who desires to be

informed thoroughly on the points treated of in it. Dr. Turnbull has not only given his own experience and supplied plenty of illustrative cases, but he has also posted himself well on the literature of the subjects treated by him. S. M. B.

DE L'ÉTAT DE MAL ÉPILEPTIQUE. By DR. ACHILLE LEROY, Bureau du Progrès Médicale. Paris, 1880.

This valuable brochure of about ninety pages is a detailed account of a number of cases dying in the so-called epileptic status after a prolonged history of chronic epilepsy. Some of the cases are those upon which Dr. Bourneville based his well-known thesis upon the subject. This epileptic status, when fully developed, seems usually, if not always, to end in death. The symptoms are very similar to those often seen in severe puerperal eclampsia,—violent frequently-repeated convulsions, with quiet or delirious coma and muscular relaxation, and decided rise of temperature. The diagnosis between eclampsia and the epileptic status must usually rest upon the history; but the great rise of temperature generally suffices to diagnose between it and uræmia. Apoplectic attacks may simulate it closely, but, except when the hemorrhage occurs in the neighborhood of the pons, rise of temperature is rare, and when occurring is probably always preceded by a fall: in cases of pons hemorrhage the convulsive symptoms are less severe, and the local paralysis usually betrays the lesion.

THE METRIC SYSTEM IN MEDICINE. By OSCAR OLDBERG, Phar.D. Philadelphia, Presley Blakiston.

Among those who are desirous of forcing the American medical profession to swallow, *nolens volens*, the metric system, Dr. Oldberg is by no means the least important, and, although one may feel slightly disgusted with the continuous effort to effect a doubtful reform, it is impossible not to admire the enthusiasm and persistency of the gifted pharmacist. The book contains one hundred and eighty smallish pages, occupied with all sorts of tables translating backward and forward metric, apothecary, and other weights, a long posological table, and numerous metrical formulæ.

ANATOMICAL ATLAS. Edited by AMBROSE L. RANNEY, M.D. New York, G. P. Putnam's Sons.

This volume consists of one hundred and twenty-three very well executed steel plates, containing four hundred and thirty-nine designs, by Professor J. N. Masse, of Paris, and various diagrammatic cuts selected or designed by the editor. The scope of the book is that which seems to be the common property of anatomical artists; the execution better than ordinary; the size and compactness such as fit it for the library-shelf, the book-table, or the dissecting-room. The parts of the figures have not their names upon them, but are numbered, referring, of course, to text-descriptions. This the editor thinks not a disadvantage: "While it does not assist a rapid review of a figure, but rather hinders it, this fact alone is the best proof of the advantages of the system. Plates must be studied, and not merely glanced at, to be of value to the student,"—a special pleading which, to our thinking, shows so ingenious a mind on the part of Dr. Ranney that if law, not medicine, were his profession, Fortune's wheel for him would turn merrily.

A TEXT-BOOK OF HUMAN PHYSIOLOGY. By AUSTIN FLINT, JR., M.D. Third Edition. New York, D. Appleton & Co.

One of the most hopeful evidences of the continual progress in the medical profession is the large sale which thorough scientific treatises like the present command. Whilst congratulating Dr. Flint, Jr., we would also congratulate the profession that so ponderous a tome as this physiology is so buoyant in the sale-market. A somewhat careful examination of various parts of the work has shown that it has been well brought up to the science of the day.

CONSTIPATION PLAINLY TREATED. By Dr. JOSEPH F. EDWARDS. Philadelphia, Presley Blakiston.

A little book of sixty small pages, containing nothing strikingly new or objectionable, but much that is sensible and pleasantly written.

GLEANINGS FROM EXCHANGES.

NEW REMEDIES—COTO, COTOIN, AND PARACOTOIN; DUBOISIN; QUEBRACHO BARK; ASPIDOSPERMIN.—F. Rohne (*Virginia Medical Monthly*, March, 1881) gives a brief account of these new remedies, based chiefly upon personal experience. Regarding the first and last, although it is now some time since they were first brought to the notice of the profession, so little has appeared with reference to their action and uses that it will not be amiss to abstract some of Dr. Rhone's remarks. As regards coto, the coto bark is derived from a tree, growing in the forests of Brazil and Bolivia, which is sometimes classed with the laurels, by other authors with the terebinthinates, but which, however, judging from its properties, possibly belongs to the Piperaceæ. Chemical analysis gives "an ethereal oil, an alkaloid, cotoin, which assumes a blood-red color on the addition of concentrated nitric acid, and paracotoin, which, similarly treated, gives a yellow color. There is also a soft and a hard extract. The presence of cotoin and paracotoin has its analogues in the cinchona barks, which yield more or less quinia, quinidia, or cinchonidia."

Prof. von Goit, of Munich, made the first experiments in Germany in 1875, partly with

powdered bark and partly with an alcoholic tincture:

℞ Coto bark, 1 part;
Eighty-five-per-cent. alcohol, 9 parts.

The results of these investigations led to the conclusion that the remedy is a specific in variously manifested diarrhœas.

Since February, 1877, Fronmüller has used coto and its preparations about 200 times: 62 times in lung tuberculosis, 38 times in typhoid, 12 times in catarrhal diarrhœa, 8 times in acute articular rheumatism, 6 times in gastritis, 6 times in pneumonia, 3 times in menstrual colic, twice in bronchitis, twice in swelled feet, once in rheuma, once in anorexia, once in diphtheria, and once in albuminuria. Colliquative diarrhœa was present 93 times, and hyperidrosis 91 times. Both complications were frequently present together. The different preparations used were tincture of coto, 100 drops daily, cotoin, 0.1 to 0.3 gramme [= 1½ to 4½ grs.], frequently repeated, and paracotoin in larger doses; the soft extract was also used, in doses of 2 to 10 pills daily, each weighing 0.006 gramme.

Coto not only exerts a marked influence in diarrhœa and hyperidrosis, but is useful also in anorexia. In 85 cases of diarrhœa, coto tincture was used successfully 50 times, with benefit 26 times, and without effect in 9 cases. After several days, many cases of colliquative diarrhœa relapsed, but were easily controlled, and normal stools soon followed. The principal advantage in the use of this remedy is that it is well tolerated, and improves the appetite, instead of diminishing it, as do opium, tannin, silver nitrate, etc. In hyperidrosis, Fronmüller ordered tincture of coto 91 times,—34 times with perfect success, 36 times with improvement, and 21 times without result. The beneficial action appears to consist in the augmentation of the skin circulation, which usually lasts but one night, sometimes longer. Digestion is not impaired; the appetite is frequently improved. Tincture of coto was several times used in the morning as a stomachic against anorexia.

Cotoin was used 18 times in various diarrhœas, with total cures in 9 cases, improvement in 6 cases, and with no result in 3 cases. In 18 cases of excessive night-sweats, it was successfully used in 8 cases, partly successful in 9 cases, no relief in 1 case. In five of these 36 cases, paracotoin was exhibited. One hundred drops of tincture of coto are equal to about 0.15 gramme [2.315 grs.] cotoin.

Rhone, adding the results of his experiments to those gained by other observers, concludes that coto and its preparations belong to the most active anti-diarrhœal remedies. It is particularly useful in the case of children, because it is not narcotic. It is a valuable temporary remedy in hyperidrosis. Coto is well borne, and acts as a stomachic in some cases. It is of use in the diarrhœa of typhoid. All the preparations are not of equal value: larger doses of paracotoin must be given. Cotoin has an agreeable taste, which makes it valuable for children; it may be given in powder, rubbed up with sugar. Pulverized coto may be given in the same way, or in emulsion, capsules, or wafers. The tincture is best diluted with water.

The uses of duboisin in ophthalmology are so well known to our readers that we shall not attempt to abstract Dr. Rhone's remarks on this drug.

Under the head of quebracho, Dr. Rhone gives a description of the different varieties of the quebracho and the method of its pharmaceutical preparation. He also quotes the description of its medical use given by Penzolt, of which an abstract appeared in this journal about two years ago, and adds to this the opinion of other observers going to show the value of this remedy in various forms of dyspnœa. There is, we believe, a fluid extract of quebracho now in the markets of this country.

Intravenous Injection of Milk.—Dr. Austin Meldon (*Brit. Med. Jour.*, vol. i., 1881, p. 228) says that this operation has fallen into unmerited disrepute. He has performed it with success twenty times. Twelve injections were performed in cases of phthisis, in all of which the patients had reached an almost moribund condition, with the result that in every instance, without exception, life was prolonged. In one the patient had apparently only a few hours to live, yet after the operation he rallied so much that for some months he was able to follow his usual avocations. Other cases showed similar improvement. Diarrhœa when it existed was invariably checked; in fact, it was difficult to free the bowels for the first few days. Perspiration was at first increased, afterwards lessened. Cough was always relieved. Beyond this moderate retardation of the progress of the disease, not much can be hoped for by this treatment in phthisis. Four cases of pernicious anæmia were all cured by the injection. In one the transfusion was performed twice, in the other but once. In two cases of exhaustion from hemorrhage, both recovered. In two cases of exhaustion after typhoid fever, one recovered and one died.

Dr. Meldon adds that the difficulty of obtaining and defibrinating the blood and the danger of coagulation in injecting it account for the operation not having come into more general use. Milk, however, is always at hand. Some deaths have occurred during or immediately after the operation, but in these cases the milk was either acid or kept for too long a time or too large a quantity had been injected. The milk of any animal kept in confinement is slightly acid, even when it leaves the udder, and, as the blood will not tolerate the presence of an acid, it is not to be wondered at that very unpleasant symptoms often develop when milk in that state has

been injected. To prevent the possibility of this, Dr. Meldon always adds ten grains of carbonate of ammonium to each injection. This, besides rendering it certain that the milk is alkaline, prevents the depression which so frequently follows the operation. He invariably uses the milk of the goat, as it is easier to bring that animal in close proximity to the patient, thus avoiding any unnecessary delay between milking and the injection. He never uses more than six ounces of milk. When time will not allow fresh milk to be obtained, that at hand may be boiled and strained.

Treatment of Cancer.—Mr. Jonathan Hutchinson (*Med. Times and Gaz.*, vol. i., 1881, p. 95), in a paper on the local origin of cancer, gives the following rules for treatment: 1. Primary cancers ought, wherever accessible, to be excised, or otherwise freely and promptly destroyed. 2. Since the process of absorption into the system is simply one of time, and since the prevention of it is the one point of importance to the patient, all operations for the removal of cancers ought to be done without any avoidable delay. 3. If the lymphatic glands are in the least enlarged, they ought to be taken out, the entire cluster being removed,—as well those which are not enlarged as those which are. 4. If the disease returns either in or near the cicatrix, or in the proximal lymphatics, it ought still to be regarded as possibly local, and a second free incision promptly undertaken. 5. After an operation for the removal of a cancer, the patient and his friends ought to be informed of the probability that the glands may enlarge, and impressed in the most forcible manner with the absolute necessity of immediate recourse to the surgeon should such be the case. 6. After the excision of a cancer which has involved the removal of a considerable portion of integument, great care should be taken, either by transplantation or some other manœuvre of plastic surgery, to secure a limp cicatrix which shall be wholly free from tension. 7. The removal of cancers by escharotics is a practice to be avoided (excepting, perhaps, under certain unusual circumstances), for the simple reason, if for no other, that it wastes invaluable time, and consequently involves increased risk of the contamination of the system.

Ethylate of Sodium in Nasal Polypus.—Dr. B. W. Richardson (*Lancet*, vol. i., 1881, p. 242) has used the ethylate of sodium three times with remarkable success in the treatment of nasal polypus. In two cases the polypus was small, easily discernible, and readily within reach. The ethylate was applied to the pedicle of the polypus from a probe-point of cotton-wool held in the blades of a long, pointed, curved forceps, and in both cases the growth was destroyed during the application, and was removed by afterblowing of the nose, the one application sufficing to effect a cure. The third case was one where the polypus had twice recurred after having been removed by a surgical operation. The polypus was large and far back, filling the nasal cavity. The pellet of wool as used in the other cases was here plunged into the centre of the growth and kept there three minutes. Its removal was followed by sneezing and discharge of blood, mucus, etc., and the cavity was found quite clear. There was some pain and irritation of the mucous surface for several days, but it seemed clear. The growth recurred, however, and after removing it again a few weeks later the spot from which it had grown was cauterized again, and a cure resulted. Dr. Richardson has great hopes of this treatment, which, if successful, will render a most annoying and obstinate complaint completely amenable to a simple plan of treatment. Dr. Richardson has also used the diluted ethylate in ozæna with success.

Absorbent Cotton.—"Absorbent cotton," says Mr. Frank L. Slocum, "has in the last few years taken such an important place among the necessities and conveniences of the pharmaceutist and physician that it is very desirable for the pharmaceutist to be able to procure or himself manufacture it. The manner in which it is prepared is kept secret, and there is no literature on the subject up to the present time, it is believed.

"At the request of Professor Maisch, some experiments have been made, the following process yielding the most satisfactory results:

"Take of the best quality of carded cotton batting any desired quantity, and boil it with a five-per-cent. solution of caustic potassa or soda for one-half hour, or until the cotton is entirely saturated with the solution and the alkali has saponified all oily matter; then wash thoroughly to remove all soap and nearly all alkali, press out the excess of water, and immerse in a five-per-cent. solution of chlorinated lime for fifteen or twenty minutes; again wash, first with a little water, then dip in water acidulated with hydrochloric acid, and thoroughly wash with water; press out the excess of water, and again boil for fifteen or twenty minutes in a five-per-cent. solution of caustic potassa or soda; now wash well, dipping in the acidulated water and washing thoroughly with pure water; afterwards press out and dry quickly."—*Druggists' Circular*, March, 1881.

A New Silver Salt in the Treatment of Organic Nervous Disease.—Dr. Allan McL. Hamilton (*Lancet*, vol. i., 1881, p. 291) suggests the employment of the tribasic phosphate of silver,—a salt obtained by precipitating a solution of argentic nitrate with a solution of trisodic orthophosphate. The precipitate is washed with distilled water and dried in the dark. It is a heavy powder, of a lemon-yellow color, darkening slightly on

exposure to the light. Dr. Hamilton has given this salt for months, in doses varying from one-third to one-half of a grain, without any skin-discoloration whatever, and he says that its administration is unattended by the gastric irritability that so often follows the use of either the nitrate of silver or the phosphide of zinc; at the same time, its therapeutical effects are much more pronounced. It is best given with some such excipients as argol and glycerin, for vegetable substances tend to decomposition, and for this reason Dr. Hamilton has discarded confection of roses as an element of the pill-mass. The cases in which he has found this drug useful are sclerosis of the posterior columns; cases of more or less acute myelitis, with disturbance of the bladder and rectum; cases of sclerosis of the nervous substance; and cases of inveterate epilepsy the result of gross inflammatory intracranial changes. He is now giving the drug to patients with cerebral tumor and general paralysis, hoping to produce even in these cases some amelioration.

Permanent Pictures on the Retina.—Dr. W. C. Ayres (*New York Medical Record*, March, 1881) alludes to the fact that it is possible to produce pictures on the retina which can be examined after the death of the animal, and endeavors to answer the question as to whether these pictures can be made use of in medico-legal practice. If a rabbit is confined to a dark room until a sufficient quantity of "visual purple" has accumulated in the retina, and is then exposed to the light with proper precautions, an image of some external object can be made to form itself on the retina. As the visual purple disappears in the light, the animal must be killed immediately if the image is to remain long enough to be examined. While working with Kuhne in Heidelberg, Dr. Ayres endeavored to make an "optogramme," or retinal image of the kind under discussion, and procured a large negative of a photograph of Helmholtz, intending to present the picture as a testimonial to the distinguished professor. Arranging the animal with every possible precaution, and exposing the immobilized eye to the action of light coming from the picture of Helmholtz, Dr. Ayres, after a great amount of trouble, succeeded in producing a picture of Helmholtz,—that is, of his shirt-collar and the end of his nose. Dr. Ayres concludes that it is utterly idle to look for the picture of a man's face, or of the surroundings, on the retina of a person who has met with a sudden death, even under the most favorable circumstances.

A Case of Chronic Vomiting in which no Food was taken but Koumiss for Sixteen Months.—At a recent meeting of the Clinical Society (*Brit. Med. Jour.*, vol. i., 1881, p. 274) Dr. H. Sutherland read notes of the case of a girl 24 years of age on admission, who had been under his care for five years. One year and seven months ago vomiting commenced; the attack came on at first only once a fortnight, but lately it had occurred always once, and sometimes five or six times, a day. As far as could be ascertained, there was no organic disease of the stomach, no tenderness on pressure, cachexia, nor any other constitutional symptoms. Every known remedy was tried to allay the vomiting,—bismuth, opium, hydrocyanic acid, creasote, carbolic acid, hyposulphites, etc.,—without any satisfactory result. All attempts to cure the case by dieting had failed; and the patient could keep nothing on the stomach as food, except koumiss, which she had taken for sixteen months. She was, however, able to retain a quinine and orange mixture, and also sherry in small quantities, for brandy made her sick immediately. The uterus was not displaced. In the discussion following the reading of Dr. Sutherland's paper the employment of koumiss was highly spoken of by several gentlemen, who recommend it especially in the vomiting of phthisis.

Crystallized Aconitia in Facial Neuralgia.—As a result of many experiments with this substance, Dr. A. Dumas (*Med. Times and Gaz.*, 1881, vol. i. p. 97; from *Jour. de Thérap.*) arrives at the following conclusions: 1. Duquesnil's crystallized aconitia is an energetic medicinal substance of great efficacy in facial neuralgias, especially the congestive, and in some other neuralgias *a frigore*. 2. It is useful in catarrhal affections in general, in which it may replace the different preparations of aconite. 3. It should be preferred to all other kinds of aconitia, which are ill defined and unequal in their actions. 4. It is of little efficacy in tic-douloureux, producing only temporary sedative effects. 5. Tolerance is obtainable for it as well as for other alkaloids when it is methodically administered. 6. It may be continued for a long time without any fear of its becoming accumulated in the system. 7. It should be given in very much divided doses, with due intervals,—at first in small doses, and gradually increased. 8. Except in tic-douloureux, it should be continued only in medium doses. Granules carefully dosed up to $\frac{1}{240}$ grain of the alkaloid or $\frac{1}{120}$ grain of the nitrate should be preferred.

Nitrite of Amyl as a Disinfectant of Urine.—M. Weiser claims for nitrite of amyl remarkable disinfecting powers, and employs it as a disinfectant in chronic catarrh of the bladder, using it as an injection in the proportion of three drops to three hundred grammes of water. For the disinfection and conservation of urine to be submitted for examination, he prefers nitrite of amyl to phenic acid.

Argyria following the Frequent Pharyngeal Application of Nitrate of Silver.—A woman aged 46 years noticed a bluish discoloration of the entire cutaneous

surface following repeated pharyngeal cauterizations with the silver nitrate stick. Similar cases have been recorded, one by Krishaber and a second in the *Gazzetta Medica Italiana* (1862). The absorption of the silver salt takes place in part from the mucous surface of the cauterized portion, but principally from the intestinal surface, the products of cauterization being conveyed to the alimentary canal.—*Archives Méd. Belges; Druggists' Circular.*

MISCELLANY.

GUY'S HOSPITAL.—It is assumed that the difficulty at Guy's Hospital is now virtually terminated in favor of the medical staff, by the publication of a series of regulations bearing on the nursing arrangements to be observed in future. These virtually concede the principal demands originally made by the physicians and surgeons, and they provide, further, for the proper limitation of the authority and duties of the head of the nursing department. A lady-nurse is to have charge of each ward, and to have under her direction two head-nurses; and special provision is made for retaining the services of the nurses in the wards to which they are appointed, thus removing the highly-objectionable feature of frequent changes, against which there has been a very justifiable outcry from the first occurrence of the differences. Another improvement is that at the end of twelve months' service as probationers candidates for the post of nurse will be required to exhibit a certificate, signed not only by the matron, but also by the medical officers.

MEDICO-DRAMATIC CRITICISM.—The *Lancet*, calling attention to Mr. Tennyson's new drama, "The Cup," now being played in London, says that the male and female actors who have been poisoned by the same draught show quite different toxic symptoms. Mr. Irving says,—

> "I pray you lift me,
> And make me walk awhile; I have heard
> These poisons may be *walked down:* my feet
> Are tons of lead."

He is then partially raised by one of his retinue, but dies apparently in convulsions, with marked opisthotonus. On the contrary, Miss Ellen Terry, who has swallowed somewhat less of the poison, lives long enough to see the other party die, and then herself succumbs *quietly* in the arms of one of her handmaidens. The feeling of weight in the limbs points to opium-poisoning; but, then, why the convulsions? and why do not both actors show the same symptoms?

PROFESSOR R. O. COWLING, so well known as editor of the *Louisville Medical News*, died April 2, 1881, of rheumatism attacking the heart.

BACKACHE.—Mr. Wm. Squan, writing to the *British Medical Journal* (vol. i. p. 229), says that many weak-looking girls owe the pain in the back which they complain of as being worse in the morning to sagging of the bed. He suggests a pillow under the spine.

A NEW public chemical laboratory is about to be opened in Paris, where there will be experts at the service of the public prepared to analyze on demand all articles of consumption,—wine, coffee, chocolate, etc.,—for very small fees.

"PORTAGIOUS" DISEASE.—Medical Inspector Gibbs, U.S.N., suggests in a letter to the *New York Medical Record* the word "portagious" to designate those diseases produced by portable germs, which are *carried into contact*, as the etymology implies.

DR. CANQUOIN, the inventor of the paste of chloride of zinc known by his name, has recently died at Dijon, in his eighty-sixth year.

NOTES AND QUERIES.

OBITUARY.

ARMY MEDICAL SCHOOL, ROYAL VICTORIA HOSPITAL,
NETLEY, 30th March, 1881.

MY DEAR SIR,—I cannot describe the sorrow I feel at the sad tidings which your circular note of the 25th ultimo has just conveyed to me, nor can I in any adequate manner express my sense of the immense loss surgical science has sustained—especially the science of military surgery—by the death of your indefatigable and talented assistant, Surgeon Otis. Still I feel I must write a few words to say how deeply I sympathize with you and with all the medical officers under your direction in the grievous loss you and they have sustained in the death of so distinguished a member of your corps. Military surgery and all who are engaged in its practice in every part of the world—and, I might add, every one who may happen to be in need of military surgical help—owe, under the liberality of the United States government and your auspices, a debt of gratitude to Surgeon Otis which, though it can never be repaid, will never be forgotten as long as the great "Surgical History of the War of the Rebellion" and his other admirable works exist. It is with perfect truth that you remark the death of Surgeon Otis will be deeply deplored not only by the members of the medical profession in his own service and country, but also by the medical profession of the whole world.

Believe me to be,
My dear Sir,
Very faithfully yours,
[Signed.] THOMAS LONGMORE,
Surgeon-General, etc.

MAJOR-GENERAL J. K. BARNES,
Surgeon-General,
United States Army, etc., etc., etc.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM APRIL 3 TO APRIL 16, 1881.

MOFFATT, P., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Camp Spokane, W. T., and ordered to Fort Walla Walla, W. T., until further orders, for medical treatment. S. O. 35, Department of the Columbia, March 20, 1881.

BIRMINGHAM, H. P., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—So much of par. 1, S. O. 62, March 17, 1881, from A. G. O., as relates to him, is suspended until May 1, 1881. S. O. 85, A. G. O., April 14, 1881.

COOPER, GEORGE E., LIEUTENANT-COLONEL AND ASSISTANT MEDICAL PURVEYOR.—Died at San Francisco, Cal., April 13, 1881.

PHILADELPHIA, MAY 7, 1881.

ORIGINAL COMMUNICATIONS.

THE TREATMENT OF HIP-JOINT DISEASE BY THE PHYSIOLOGICAL METHOD OF EXTENSION.

BY JOSEPH C. HUTCHISON, M.D.,
Surgeon to the Brooklyn City Hospital.

Read before the Philadelphia Academy of Surgery, April 4, 1881.

THE object of this paper is merely to describe a plan for the mechanical treatment of morbus coxarius which I believe is more simple, effective and agreeable to the patient than the methods ordinarily employed.

While it is unnecessary, before this Society of experienced surgeons, to call attention to the symptomatology of hip-joint disease, I desire to refer to one symptom, viz., *fixation of the joint.* And this I do for the reason that it bears an important relation to the treatment which I propose to submit for your consideration this evening, and also because it is one of the most characteristic symptoms of the disease. Fixation of the diseased joint to a greater or less degree is a symptom which has not always been duly appreciated. Some of the best surgical text-books have omitted to mention it; and yet I will venture to say that there is not an experienced surgeon present who has not observed it as an early symptom of hip-disease. Muscular rigidity may not be sufficient at first to arrest motion in the joint, and it may be overlooked by a careless observer, but as the disease advances this rigidity generally increases, until the arrest of mobility becomes complete and is recognized by all.

Barwell ("Diseases of the Joints") enumerates "more or less immobility" among the symptoms of the first stage of hip-disease, the immobility increasing as the disease progresses.

Professor A. C. Post,* in describing the symptoms of the second stage of morbus coxarius, says, "The joint seems often in this stage to be anchylosed: the rigidity, however, is the result simply of muscular contraction. The division of the muscles which surround the hip-joint, or the evacuation of the fluid contained in the capsule, will remove this rigidity, which seems to constitute the anchylosis."

* American Medical Times, vol. ii. p. 278.

Bauer,† in calling attention to some "symptoms" of morbus coxarius "of great importance," says, "*The immobility of the affected joint* is so complete that scarcely the slightest movement can be effected." On p. 265 of his "Orthopædic Surgery," he says, "The mobility of the joint may be impeded or entirely suspended;" and on p. 269, "The joint, being more or less tender, is well taken care of by the patient and protected against incidental injuries: one of the means of doing this is the voluntary effort of the muscles to keep the joint at rest."

Sayre says,‡ "In the first stage very limited motion can be made at the joint. Abduction, adduction, and rotation are limited, and when carried beyond a certain point the pelvis at once moves with the limb, giving the patient an appearance as if complete anchylosis had taken place at the hip-joint. But there is no real anchylosis present in this stage of the disease. There is anchylosis perfect and complete to all *appearance*, but it is due simply to muscular rigidity. . . . The immobility which is present in the second stage, resulting from over-distention of the capsule and muscular rigidity, is usually well marked. *If left to itself, the rest which is so essential to the joint is procured by the firm muscular contraction which prevents motion, and this is so perfect, in many instances, as to assume the appearance of genuine bony anchylosis.*"

Dr. Shaffer§ says that "persistent reflex muscular spasm is an invariable symptom of chronic osteitis of the hip-joint. . . . This muscular spasm increases, as a rule, with the limp; but many months, or even years, may pass before it reaches the point where *all movement of the joint is arrested*, and cases may occur where the spasm simulates *actual anchylosis.*"

Immobility of the joint is both voluntary and involuntary. It is not due merely (1) to reflex contraction of the peri-articular muscles, because it continues also during sleep, when all voluntary action is suspended, but likewise (2) to intra-capsular effusion, which produces not only immobility of the joint, but various distortions of the limb as well, as has been proved by the well-known experiments of Prof. Weber, of Bonn, which consisted in

† New York Journal of Medicine, vol. ii., N. S., p. 162.
‡ Lectures on Orthopædic Surgery, p. 238 *et seq.*
§ The Hysterical Element in Orthopædic Surgery, pp. 24, 35, 36.

injecting the normal cotyloid cavity with water; and (3) to the voluntary effort of the patient to keep the joint at rest, because the slightest movement develops pain, and, moreover, if he is induced to execute a movement it will be seen that it is not the hip-joint that moves, but the whole pelvis at its lumbar articulation.

Rigidity of the joint is best shown by undressing the patient and placing him upon his back on a firm flat surface. The sound limb is flexed so as to place the knee in contact with the chest, when the spinous processes of the vertebræ and the back of the pelvis will lie flat upon the table: while the sound limb is held in this position, the suspected limb becomes more or less bent at the knee, and the popliteal space cannot be brought to the table by the efforts of the patient. When the sound limb is released from its flexed position and the patient directed to extend the diseased limb so as to bring the popliteal space down to the table, the pelvis is tilted and the lumbar vertebræ curved so that the hand can be placed between the child's back and the table.

This examination can be made without giving the patient pain, and it enables the surgeon to determine with great certainty the presence of hip-joint disease, even in the very early stage; indeed, I may say, with quite as much certainty as at a later period. I dwell with some emphasis on this diagnostic point, believing as I do that it has not received the attention that it merits, and all the more because an early recognition of the disease is extremely important.

I do not wish to be understood as asserting that fixation of the joint by reflex muscular contraction is pathognomonic of hip-joint disease, for this condition often exists in hysterical joint-affections to such a degree as to simulate true anchylosis. But a careful observer will be able to distinguish the real from the mimic. In hip-disease the rigidity is persistent and unvarying night and day, and cannot be overcome when the patient's mind is diverted. In hysterical joint-affections the muscular contraction varies, and can be subdued by gentle, persistent efforts to flex and extend the limb when the patient's attention is drawn away, and it disappears during sleep. Various emotional phenomena are also observed in this class of cases, so that a little clever management will enable the surgeon to recognize the hysterical element. In doubtful cases we may be aided by the use of the faradic current, as suggested by Shaffer. In the true muscular spasm of joint-disease the faradic reaction of the muscles is diminished, whereas in hysterical conditions of the joints the muscles respond normally to the faradic current. This is, I think, a valuable suggestion.

Increased temperature of the part, which is one of the most characteristic symptoms of inflammation in most of the joints, cannot, unfortunately, be relied upon in the case of the hip-joint, which is situated so deeply that an abnormal temperature cannot in all cases be recognized by the surface-thermometer.

In the treatment of hip-disease we direct our attention to the relief of pain and the prevention of deformity. By the methods used to accomplish these indications we control the disease, or rather we put the patient in the best possible condition for getting well: we remove as much as possible the *morbi causa*. We do not cure the disease, but we may remove the condition which keeps up and aggravates the morbid irritation, which, while continuing, prevents any real improvement. *What is the cause of the pain* about the hip- and knee-joints, which in many cases is entirely located at the latter joint? This inquiry seems to be especially pertinent because clinical observations teach us that the severity and duration of the disease are in proportion to the degree of pain the patient experiences, and recovery takes place *pari passu* with the diminution of the pain. And whatever increases the pain, as a general rule, increases also the articular disease. Therefore it is important to ascertain the cause of the pain, and to remove it if possible, in order that the patient may be put in a condition favorable for recovery. A certain amount of pain is caused by the distended vessels pressing upon the nerves involved in the inflammation: this is true in all inflammations, but it is especially so in unyielding textures, such as enter into the structure of the hip-joint; and when we consider the close relationship of the nerve-trunks both to the hip- and the knee-joint, the anterior crural sending a branch to the hip-joint and the obturator contributing a branch to the capsular and round ligaments, and also to the inte-

rior of the knee-joint and the inner side of it, it is not surprising that they should suffer when inflammation exists in the hip-joint. But the most important influence by far in the production of pain is the violent spasmodic contraction of the muscles which press together the inflamed and sensitive surfaces of the head of the femur and the acetabulum. This is shown by the prompt relief from the most acute suffering which is at once afforded by simply taking hold of the ankle and extending the leg forcibly but gently, or by applying the weight and pulley, or by placing the patient upon a high shoe and crutches, extension being made by the weight of the leg. The portative apparatus of Davis, and its numerous modifications by others, designed to produce extension as well as to fulfil other indications, show the importance their designers or modifiers attach to overcoming muscular contraction in order to relieve pain. And, notwithstanding Barwell ascribes the pain to other causes as well, the much greater importance which he attaches to muscular contraction as a causative agent is indicated by his repeated statements that while the sharp pains continue there is constant muscular contraction, pressing the bones together, which is proportionate to the continuous wearing pain which is usually referred to the knee.

Extension, both for the purpose of subduing abnormal contraction of the muscles and for correcting the malposition of the limb, may be regarded as a *sine qua non* in the treatment of hip-joint disease. So far as I know, extension as a *curative agent* in the treatment of morbus coxarius was first used by the late Dr. William Harris, of Philadelphia, and in 1839 he published an account of three cases, two of which were treated by such an apparatus as was used in the treatment of fractures of the thigh in the straight position, and one with Hagedorn's splint. For many years previously, extension and counter-extension had been used for the purpose of overcoming deformity after the disease had subsided, but not for the purpose of relieving pain and controlling the morbid condition. The suggestion of Harris seems to have been forgotten, and for a long time we heard but little said of mechanical extension, except for removing deformity. At the present time the importance of extension as a means of curing morbus coxarius, as well as for preventing and overcoming deformities, is almost universally recognized. This is shown by the number and variety of appliances which have been devised to satisfy this indication.

Does extension accomplish anything more than the relief of reflex muscular contraction and its consequences, and the prevention or correction of deformity?

It has been claimed by respectable authorities that we can by extension separate the head of the femur from the acetabulum; but it has been demonstrated by the well-known experiments of Barwell, made on healthy subjects, recently repeated by Bradford, of Boston,* that the bones cannot be separated to an appreciable extent by any amount of extension that can be applied, even when all the muscles and the capsular ligament itself have been divided. Weber affirms† that the head of the femur in its normal condition is held firmly in place by atmospheric pressure, while Barwell maintains that it is kept in place by what he calls the "cohesive contact" which takes place between the joint-surfaces. The question must still be regarded as under judgment; but I incline to the opinion of Barwell, that extension affords relief by preventing the diseased surfaces from being violently jammed together, and not by separating the head of the femur from the acetabulum.

In the treatment of hip-joint disease, the essential indications are, in addition to improving the patient's general health by judicious medication and proper hygienic influences, (1) that there shall be sufficient *immobility* of the joint to prevent the injurious effects of the motion and consequent friction of the inflamed surfaces; the immobilization of other joints when inflamed is considered an essential part of the treatment, and, with due respect to the opinions of some very high authorities, I can see no reason why the hip-joint should form an exception to this surgical axiom; (2) to overcome muscular spasm, and to obviate and correct deformity by means of *extension;* (3) to remove the weight of the body from the joint, and to provide means for enabling the patient to take open-air exercise with comfort and safety.

The method which I have found most satisfactory and comfortable both to my-

* Boston Medical and Surgical Journal, November, 1880.
† Müller's Archives, 1836, p. 54.

self and to my patients I have designated in another place "the physiological method,"* and I must still claim the privilege of using the word "method," notwithstanding I have been sharply criticised by a respectable reviewer for having done so. The plan consists in placing upon the foot of the sound side the shoe ordinarily used for shortened leg (which should be high enough to prevent the toes of the diseased side from touching the ground), and putting the patient upon a pair of crutches. By these simple appliances all the indications are fulfilled for the successful treatment of morbus coxarius and *the prevention of deformities*, which are sure to occur unless obviated by appropriate means.

Immobility sufficient to prevent injurious motion and friction is obtained, as we have already seen, by nature's expedients,—chiefly the reflex contraction of the peri-articular muscles, aided by intra-capsular effusion and the voluntary efforts of the patient to keep the joint at rest, in order to avoid pain. Nature fixes the joint more satisfactorily and in a kindlier way than we can by our most ingenious appliances.

Extension is made by the weight of the suspended diseased limb, which is equal to one-fifth of the weight of the entire body, and is sufficient to overcome the muscular spasm which increases the pain and perpetuates the disease by jamming together the inflamed surfaces. The extension obtained by the limb of a child weighing, for example, sixty pounds would be twelve pounds and a half, which is more than can be borne when the case is treated in bed by the ordinary weight and pulley. Extension produced by the weight of the limb is efficient, and at the same time more grateful to the diseased parts, because it is less arbitrary and constraining, and therefore excites less reflex resistance than any method I had previously employed. The muscles are persuaded, so to speak, to relax, instead of being compelled to yield by force, which irritates and stimulates them to resistance and spasm. Kindly treatment is often more effective than compulsion in accomplishing our purposes; and this is true as well in physic as in morals. There is a certain instinctive unconscious recoil in the mind of every patient, young and old, against all the various devices of constraint or imprisonment which a splint or apparatus implies.

Muscular rigidity should not be confounded with muscular spasm. The former may exist to such a degree as to produce apparent anchylosis, and yet the patient experiences no pain, but when reflex spasm takes place violent pain is developed. Extension gives relief not by overcoming *completely* the muscular rigidity, — this would not be desirable, because too much motion would then be permitted in the joint,—but by stretching the contracted muscle sufficiently to prevent the development of reflex spasm.

The patient should walk or stand upon the crutches three or four hours every day; and there is no difficulty in inducing him to do this when he has learned that by suspending the limb he is relieved from pain. The use of the crutches for three or four hours daily appears to relax the muscular rigidity sufficiently to prevent the recurrence of the reflex pain at night. Why this should be accomplished more efficiently when extension is made by the weight of the limb unencumbered by the rigid appliances ordinarily used, which do not produce extension as is claimed by their respective authors, the extension which they are supposed to make being made merely by the weight of the limb, is easily explained. The unyielding iron apparatus and the perineal band irritate the muscles and worry the patient, so that muscular spasm is not so completely over-

* Contributions to Orthopædic Surgery, Putnams, 1880.

come as when extension is made without their use. It is a delusion to suppose that they add in the slightest degree to the force of the extension; and, if they did augment the extension, it would be unnecessary, for the weight of the limb gives all the extension that is required.

The objection to the extension splint of Davis and its various modifications, that the extension strap slackens or the instrument bends in walking, so that all extension is lost, is said to have been remedied by a splint devised by Shaffer, of New York. But if, as I maintain, the weight of the limb gives all the extension necessary, why should we encumber our patients with irksome appliances, however well they may accomplish their designs, which require the unremitting vigilance of the surgeon to maintain their efficiency and to prevent excoriations? The portative appliances in ordinary use are designed to accomplish diverse indications, and may be divided into two classes. The first, represented by the apparatus of Davis and its modifications, is intended to combine *motion of the joint with extension;* while the purpose of the instruments of Bauer, Barwell, Andrews, and others, is to secure *immobility of the joint with extension.* Now, with all due respect for the surgical skill and ingenuity of these respective gentlemen, I am convinced that neither class of appliances accomplished the objects claimed for them. A close observer will notice that a patient who wears an instrument belonging to either class swings the whole pelvis as he walks; and this is due to the movement which takes place between the sacro-lumbar articulations; but there is no motion at the hip-joint. A kind and overruling Providence compels immobilization of the joint in spite of the efforts of the surgeon to prevent it.

That the instruments of the second class do not fix the joint must be evident when we consider that they only extend upward an inch or two above the joint, and no instrument can control the movements of the joint which does not extend a considerable distance above (as high as the thorax) as well as below the articulation. There is manifestly a disproportion between the object to be attained and the power applied to attain it. No surgeon would expect to fix the knee- or elbow-joint by splints unless they were carried both above and below the joints for some distance.

If the appliances referred to are wholly inefficient to accomplish what is claimed for them, and are deceptive as to the manner in which results are obtained, how do we explain the fact, it may be asked, that so much improvement has been reported from them, when compared with others not having their features? These favorable results may be accounted for by the fact that the use of portative instruments has liberated patients from confinement within-doors, and enabled them to enjoy the benefits of open-air exercise, instead of being treated in bed as was formerly done, and also because *the principal indications—immobility and extension—are obtained independently of the apparatus used, by the reflex contraction of the muscles which surround the hip, and by the weight of the limb.*

These appliances have done good service in the cause of humanity, and are creditable to surgical ingenuity; but I am sure we can accomplish results equally satisfactory by simpler and less irksome expedients.

It has been objected to the physiological method of extension that unless the children are watched constantly they may lay aside their crutches and bear the weight of the body upon the limb. This I have known to occur; but when they suffer pain from this cause they are not likely to repeat the experiment, for even very young children soon learn that suspending the limb gives relief. The remedy for the pain is in their own hands, and they readily apply it with the co-operation of the parent. But the same objection exists to other appliances. Every surgeon knows that when he applies any of the ordinary splints he is sure to find it relaxed the following day, on account of the pain and irritation they produce, and it requires the constant supervision of professional skill to keep it properly adjusted: it cannot be left to the care of the nurse or parent. And the same objection can be made to the weight and pulley. If the hospital ward is visited at a late hour of the night, we will often find patients who have the weight and pulley applied lying on their sides with the diseased limb flexed, so that extension is made from the knee instead of the hip.

Another objection which has been urged to physiological extension is that it is efficient only when the patient is in the erect position. Abundant experience has shown that the weight of the limb acting upon

the peri-articular muscles gently, without irritating them, for three or four hours daily, is sufficient to overcome the tendency to spasm of those muscles, as already stated, to such a degree that the joint-surfaces are not jammed together by muscular spasm. Why this should be so when extension is made without apparatus, while we get the same amount of extension with apparatus and by the same means, viz., the weight of the limb, has already been explained. The point is that the physiological extension is made without irritating the parts or stimulating the muscles to resistance, and therefore the spasm is more completely overcome.

It has also been objected that the plan of treatment herein advised does not prevent the deformities which are so liable to occur in hip-disease.

Deformities the result of muscular contraction can only be prevented by overcoming such contraction; and no plan to accomplish this has been suggested except that of extension in one way or another, or myotomy. The simplest and least inconvenient method of producing extension is by suspending the limb; and this produces as much extension as can be borne as a rule, or as can be made by more complicated expedients, and is, therefore, to say the least, quite as efficient in preventing and overcoming deformity as any other method. Even with the weight and pulley applied in bed, more weight cannot be borne than that of the suspended leg itself. It has been said that as the powerful muscles which control the hip-joint lift and swing the parts below, they cannot be extended merely by the weight of the limb. This I am sure is an error, for it is the abnormal contraction of these muscles, the approximation of their points of origin and insertion, that is to be overcome by the weight of the limb. The same objection would apply to extension made by a weight applied with the patient in bed. In the one case, as in the other, the leg is supported and held in contact with the body by the strong peri-articular muscles, whose abnormal contraction must be overcome by extension. Since I began to use this method I have not found in any case a necessity for using any other method of extension as a *curative agent*, even at night, than the weight of the limb, except when the patient was too young or too feeble to use crutches, and in the comparatively rare cases of acute articular coxalgia attended with great constitutional disturbance, compelling the patient to keep his bed. The latter class of cases can only be treated with the long splint or the weight and pulley, the former with Darrach's wheeled crutch or the ordinary go-cart, which permit open-air exercise, in conjunction with the elevated shoe. I have, however, learned that other surgeons have found that the weight of the limb was not sufficient in exceptional cases to prevent the muscular contraction incident to the disease; and this may be my experience in the future. These cases were not, however, treated subsequently by the portative extension splint, but by the weight and pulley, necessitating the confinement of the patient to bed.

In cases of deformity from muscular contraction, a result of the neglect of proper early treatment, weight extension may be used with advantage: it enables us sooner to overcome the flexions of the limb. In such cases, weighting the heel of the shoe on the diseased side, when increased extension can be borne, also hastens the removal of the deformity.

Neither have I found it necessary in any case to fix the joint more completely than is accomplished by the reflex contraction of the peri-articular muscles, the intra-capsular effusion, and the voluntary effort of the patient to keep the joint quiet. Nature secures all the immobility required in such cases better and more gratefully to the patient than the most ingenious appliances that art can suggest.

I am aware that this paper contains no facts or suggestions which I have not previously presented to the profession, and I should not have presumed to occupy the time of your Society this evening had I not been solicited to do so by two of your most distinguished members, and on them I must throw the responsibility for my persistence in trying to awaken here an interest in a plan for the treatment of morbus coxarius which seems to me to be entitled to consideration. I was, moreover, gratified to have the opportunity to emphasize certain positions expressed in my former papers, to say that a more extended experience induces me still to adhere to the main points of my early argument, notwithstanding it has received the compliment of adverse criticism on the part of some of my reviewers, and also to say that,

although relatively a stranger to many of you, I ask no quarter, but cordially invite candid and independent discussion of the views I have expressed in this paper, to the end that we may, aided by your knowledge, skill, and experience, leave the rational treatment of morbus coxarius better understood than we found it.

Thanking you, gentlemen, for your courtesy and attention, I commit the subject to your hands.

SOME OBSERVATIONS ON THE CARLSBAD TREATMENT.

Read before the Philadelphia County Medical Society, January 26, 1881,*

BY E. T. BRUEN, M.D.

IN common with many of those I address this evening, I have used with much good effect in selected cases the Carlsbad salt. It is needful only to remind this body of the more powerful physiological action of certain drugs when administered in dilute solution, to explain the advantages of these prepared salts. One of the most original applications of the above facts to the treatment of disease will be found in a paper by Dr. John Guitéras in the *Philadelphia Medical Times* for June 5, 1880, entitled "The Therapeutic Advantages of Administering the Iodide of Potassium Fasting, with Some Remarks on Interstitial Hepatitis with Enlargement of the Liver." In this paper is discussed the advantage of administering alterative drugs in dilute solution while fasting, and the opinion is expressed that the physiological action of the drug is much intensified. I can confidently corroborate the statements of Dr. Guitéras, and as, during a recent visit to Europe, I spent some time at a number of Baths, including Carlsbad, I will offer the results of my notes: these comprise the varieties of cases I found in the habit of visiting Carlsbad, the benefit derived, the action of the waters, and the after-treatment advised by the local physicians. It must be borne in mind that the Carlsbad salts do not represent the waters as they issue from the laboratory of nature. The Carlsbad salt is merely, after all, Glauber's salt: the true waters contain, in addition, carbonate of sodium 13 grains, sulphate of sodium 20 grains, to the pint, besides a fair amount of chloride of sodium, some carbonate of lime and magnesium, with free carbonic acid, at a varying temperature from 122° Fahr. to 166° Fahr. I am inclined to think that those who consult the books published by the resident physicians at the German baths will find them to yield information comparable to the Yankee's definition of a flea, viz., "A critter which, when you put your finger on it, warn't there." However, in a recent book† by Dr. J. Kraus the reader will find a good analysis of the waters, some facts as to the climatology of the place, and, included in a letter from an ex-patient, many useful hints are given as to the method of life, the dietary most suitable, the personal hygiene, and the best route to follow in a journey to Carlsbad.

The cases resorting to Carlsbad may be divided into three classes: 1. Cases of enlargement of the liver and spleen, as a sequence to repeated congestions induced by continued dyspepsia or chronic malaria, interstitial hepatitis, or primary stage of cirrhosis, especially when jaundice and deficient intestinal digestion persist, and also cases of chronic indigestion with deficient assimilation, whether or not constipation be a prominent symptom. 2. Cases of chronic rheumatism or gout. 3. Cases of the gouty state, or those obscure cases attended with renal congestion or inactivity, as evidenced by the passage of a deficient amount of urine of low specific gravity, usually associated with deficient vaso-motor tonus. These cases are subject to transient attacks of headache or hysterical nervousness. These cases, as I shall show later, are often much benefited, some cured, by a course of the waters. The springs differ from each other chiefly in temperature, which is high where it issues from the source, ranging from 166° Fahr. to 122° Fahr., and in the amount of carbonic acid contained in them. It is usual for patients to rise about six o'clock and to spend about two hours at the spring, taking at fifteen minutes' interval three or four ounces of the water. Beginners usually indulge in from twelve to sixteen ounces a day; the amount is often carried up to twenty-four or thirty ounces. Exercise is taken while drinking the waters, and then resort is had to the hotel. Later I shall observe that a strict diet is fundamental to the success of "the

* The discussion on this paper will be found in the *Medical Times* for April 23.

† Carlsbad: Its Natural Healing Agents.

cure:" the diet consists of a light breakfast of eggs, bread, and coffee; at noon, meat (steak or chicken) constitutes the meal; in the evening the same meal is repeated. No one under the "cure" will venture on a *table-d'hôte*, or even a more liberal meal, but this strict regimen is possible, since every one eats at one of the numerous restaurants, one of the features of the place. Early hours and moderate exercise are especially enjoined. Now as to the effects produced. Most persons experience a laxative action, not a purgative effect; but I have known other cases in which the compound liquorice powder was used daily to produce movements of the bowels. Without exception, individuals experience the most profound exhaustion, and usually profound anæmia ensues. In most cases the urine is notably increased in amount, and at times is of a blackish-green color. The stools are often greenish, doubtless owing to the increased secretion of bile; in the urine the color is perhaps due to the destruction of the red blood-corpuscles. For it would seem that the alterative effect of the waters is so great as to make the systemic condition resemble that induced by too generous use of the potassium salts. Patients have frequently said to me, "Doctor, I cannot endure this treatment; it is too reducing; my strength is ebbing away." Notwithstanding this, the treatment is continued for three weeks or a month, the period of the "cure," and the patient is despatched to Ischl, St. Moritz, or some other springs the waters of which contain iron, and thus the blood-crasis is restored. In persons weakened by previous long sickness, recuperation is very slow after a Carlsbad course: indeed, it appeared to me that the treatment is pushed too far with these cases. Sir Henry Thompson has said* that he is quite as well satisfied with a smaller amount, "say six to eight ounces given daily during six or nine weeks, instead of the usual three weeks of the foreign course." I incline to think that the restricted diet contributes very much to the favorable result usually attained.

To illustrate: alcohol, or any fermented liquor, is to be used in its most dilute and purest form, or relinquished altogether; sugar, fatty matters, butter, cream, fat of meat, are proscribed; the fruits are not allowed, and vegetables and good fish are unattainable. In serious cases, a repetition of the course every three or four months is found advantageous, provided the patient's strength at all permit: too much must not be hoped for from a single course. The effect of the salts of potash, when administered continuously, is to increase the oxidation of the tissues, and anæmia is brought about.† Apparently the same effect can be brought about by the salts contained in these waters.

Let me now append the outline of the history of two cases which I had the opportunity to examine in Carlsbad, both before and after treatment:

A gentleman, a resident of one of our Southern States, had been subject to frequent attacks of chills and fever, had been through an attack of yellow fever, and had previously been broken down by life in the Southern army during our late war. The liver extended three finger-breadths below the ribs, the spleen included three times its normal area, there was continued pain over the liver, with intestinal indigestion, hemorrhoids, and constipation. After a three-weeks' course, the liver was reduced to normal size, the spleen also, but the exhaustion was extreme, there had been a loss of nearly twenty pounds of flesh, anæmia was profound, digestion was capricious, the hemorrhoidal veins dilated. In all the patient's stay at Carlsbad no more than a laxative effect had been produced by the waters. In this case, after eight weeks' stay at Ischl and St. Moritz, a general improvement occurred, and when I left him in Paris in September he was better than he had been for years, and the anæmia was yielding to small doses of iron and bitter tonics.

The second case was that of a gentleman from New York, fifty years of age, in whom the liver and spleen were also much enlarged, and dyspepsia and anæmia very pronounced. In this case, also, reduction in the size of both liver and spleen occurred, but the force of the cardiac beat was alarmingly reduced. There were attacks of fainting, with fluttering action of the heart; also numbness of the arms and legs was frequently complained of, and the temptation was strong to discontinue the treatment, but it was persevered in for four weeks. In this case recuperation has been very slow, and at date the strength of this gentleman is less than before the treatment. At the same time the appetite is good, and the anæmia is slowly abating. At the termition of the Carlsbad course the springs of Franzensbad were selected for this patient, because of their contiguity to Carlsbad. The patient's weakness after the course was so extreme that a long journey was impossible.

* Early History of Calculus and its Treatment.

† Wood's Therapeutics, p. 486.

The waters of these springs are ferruginous, and, as I shall presently state, it is the custom to follow the Carlsbad course with a tonic regimen. The cases exhibit how powerful a therapeutic ally we possess in the Carlsbad waters; but the cases must be carefully managed while under treatment.

I noticed a group of cases at Carlsbad sent there for the mitigation of symptoms, such as come-and-go headache, ascribed to vaso-motor weakness, evidenced by the tendency to change color readily. In these cases there was often associated flatulent dyspepsia. The stimulation of the carbonic acid in the waters seemed to be beneficial by equalizing the circulation: the headache would disappear, the tongue become clean, and the dyspepsia often vanished. Some English gentlemen told me they could only secure a clean tongue by an occasional visit to Carlsbad. The headache I have designated as come-and-go headache because it is peculiar in this respect, that it is not persistent, but comes on suddenly in the night or at any part of the day. It is temporarily relieved by any warm not too stimulating drink, such as these waters. I noticed, however, that warm milk frequently seemed of as much service; but the patients themselves were satisfied that Carlsbad was alone their resource.

A word as to the climate of Carlsbad. This is frequently variable, as in all high latitudes, and an abundant supply of clothing of different textures is advisable.

The after-cure consists in despatching the patient to some mountainous resort possessed of a ferruginous spring. At present two localities are fashionable,—Ischl, in the Austrian Tyrol, and St. Moritz, in the Engadine. Ischl, in my opinion, has superior attractions for "after-cure" patients. The climate is equable, the diet good, the hotels comfortable, and the adjacent country interesting. For instance, one is then close to the mines of Saltzburg; the Austrians frequent Ischl; variety and diversion in the surrounding life are thus obtainable. St. Moritz is situated at an elevation of six thousand feet above the sea. It is a beautiful valley, surrounded by imposing scenery. But the climate is variable; they have but one really comfortable month, and that is sometimes July, and sometimes August. The adage of the inhabitants is "nine months winter, and three months cold." I was there in the latter part of July and the first part of August: variations of temperature were frequent, as much as fifteen or twenty degrees, sometimes, in a day, the average height of the thermometer being 60° Fahr. to 65° Fahr. The sun at mid-day is often hot, but the climate is too cold for anæmic people. The hotels are not well kept, and, what is worse, the drainage of both hotels and village is conducted into the river Inn. This river runs low during August; the drainage-pipes are thus exposed above the surface of the water, and the air around the large hotels is very impure. Were it not for the elevation and the wonderfully-exhilarating alpine air, I fear the effect of this vitiated atmosphere would be very noticeable. The matter of drainage is equally imperfect at Carlsbad, and it is a serious drawback to its otherwise great advantages.

I can recommend, however, the waters of St. Moritz. The proportion of iron is very small, the water is universally well digested, and, as it is rendered sparkling by the carbonic acid, it is very acceptable to the taste. The baths, which are a feature of the place, are very agreeable. Water from a spring similar to that used for drinking is employed, and the stimulating effect of the carbonic acid to the skin reminds one of the exhilarating effect of an ocean-bath. The waters are warmed by steam to any desired temperature, and after leaving a bath the circulation is equalized, and, as I said, the sensation is one of exhilaration. The bath-rooms are comfortable, but the tubs are wooden, without tile lining, so common elsewhere, and I fear they are not as clean as might be.

The remarks on the climatology of St. Moritz do not apply to the other regions in the Engadine. Pontresina, a village a few miles distant, is situated in a smaller valley, and is much less visited by high winds; but, as there is no iron spring, a daily ride to St. Moritz is obligatory. After a course of life as above described, careful diet is most important, and, although it is said to be well to leave these high latitudes gradually, after conversing with many travellers I incline to think a return to Paris or England, or for Americans a return to the United States, is far better, even at the cost of returning a second time to Carlsbad. Fish, oysters, and fresh vegetables are articles of supreme importance in a dietary, and these cannot

be procured unless in the localities I have named.

The above facts are personal observations. I have no personal testimony as to the value of the waters in the treatment for prevention of calculi, renal or hepatic.

For a treatise on the former subject I recommend the perusal of Sir Henry Thompson's work, already alluded to. For the latter, the assertions of J. Kraus must be consulted. To his work I must also refer for a statement that these waters are of value in the treatment of diabetes, although no details are given as to results.

At Carlsbad the Giesshübler Lauerbrunn water is recommended as a suitable drinking-water, the imperfect draining of the place rendering the natural water undrinkable. It is a very feebly alkaline water, of agreeable taste, but, as an alkaline water, inferior to Vichy or seltzer water, in my estimation.

ETHYLENE BICHLORIDE AS AN ANÆSTHETIC AGENT; WITH A CONSIDERATION OF ETHYLENE METHYLETHYLATE, ETHYLENE ETHYLATE, ETHYL NITRATE, AND ETHYLIDENE BICHLORIDE.

BY EDWARD T. REICHERT, M.D.

ETHYLENE BICHLORIDE, or ethene bichloride, or better known as "Dutch Liquid," and isomeric with the ethylidene bichloride, or ethidene dichloride, which has lately attracted attention through the investigations of the British Chloroform Committee, was first used by Simpson as an anæsthetic agent, and more recently by Nunnelly,* who, after making fourteen experiments on the lower animals and a number on his own students and patients, states that he found it in every way agreeable. In mammals thirty or forty minims were sufficient to cause complete anæsthesia in from two to five minutes, and with a like quantity six out of seven students were rendered completely insensible, although a second dose of twenty minims was occasionally given. In six surgical cases he used it with perfect success, and later in his paper concludes that chloroform is in no respect superior, for the animals were rendered perfectly anæsthetized in quite as short a time, showed no uneasiness while passing into this condition, remained perfectly still while in it, and, in recovering, were altogether free from any unpleasant symptoms; and, further, that if animals were rendered so profoundly anæsthetized by chloroform as with it, they would not have recovered, and that although just as small a quantity would cause anæsthesia as would chloroform, yet a much larger quantity was required to destroy life, and hence its greater safety. Simpson,† who had previously used it, stated that when its vapor was inhaled it caused so much irritation in the throat that but few persons could endure inhaling it until anæsthesia was produced. He, however, certifies that he has seen it inhaled perseveringly until anæsthesia and its usual phenomena were present, and that this condition was not attended with any excitement of the pulse or subsequent headache, and when he took it himself it produced such a degree of irritation in the throat that it did not disappear for many hours. Snow‡ found it to be a powerful agent, but deems it unsafe.

Although not much in the way of recommendation can be said for this preparation from the results of Simpson's and Snow's investigations, yet if we are to judge from those of Nunnelly it must be certain that in so far as its anæsthetic properties are concerned nothing more could be desired; and, indeed, the only objections urged by the two former investigators are its irritancy and its dangerousness. That Simpson laid entirely too much stress on the first of these objections must be inferred, because Nunnelly found it very pleasant to inhale; and so far as my personal acquaintance with the drug is concerned, both in regard to its administration to others as well as personally, it is certain that, while it does possess irritant properties, and does cause distress when first inhaled, the distress is certainly nothing like as severe as we are led to infer, nor is it much, if any, worse than that caused by the inhalation of ether; and as regards the dangerousness of the ethylene, a difference in opinion as to the degree of its dangerousness is also apparent. Still, it will be admitted that the weight of the evidence in its favor or disfavor rests with the assertion of Nunnelly, who made the most elaborate and detailed study, and, with such a weight of recommendation, it

* Transactions of the Provincial Medical and Surgical Association, xvii., 1849, p. 208.

† Edinburgh Medical Journal, viii., 1848, p. 740.

‡ Anæsthetics.

is apparent that its reintroduction to the profession is but a matter of time. It therefore seems that the present is a fitting time for the reconsideration of this compound, and for a detailed study of its properties as an anæsthetic agent, because we find the confidence in chloroform so universally shaken, the slowness, uncertainty, and many other practical disadvantages of ether so keenly felt, and that the anæsthetics recently introduced, and which were oftentimes lauded to the highest tension, have miserably failed to fulfil the promises made for them, and have even added their victims to the already ghastly anæsthetic holocaust. Hence the profession is eagerly searching for a compound which will prove to be as safe as ether and to possess all the advantages of chloroform; and, while such a stimulus exists for research and experimentation with this class of compounds, we must expect, even at this time, when the physiological laboratories of our institutions of medical learning are open for original research, and scarcely any investigator can plead an absence of facilities for vivisection, to find those who are so utterly reckless as to imperil the lives of their patients by experimenting on them before a proper physiological study has been made on the lower animals and the anæsthetic satisfactorily proven to be safe. How it is that these workers of death presume to be invested with the moral and legal right to unnecessarily jeopardize the lives of their patients is inexplicable.

From this it will be understood that the object of the writer in the preparation of this paper was to determine by an experimental investigation on the lower animals as to whether or not this anæsthetic especially, which appears so promising, is a safe one to use on the human being, and if it does possess any decidedly dangerous properties to point them out, so that if necessity or preference should ever call for its use we will be forearmed by being forewarned, and thus, anticipating certain dangerous results, can meet them promptly and efficiently, and, when it is considered that the degree of danger of any anæsthetic lies practically in its effects on the circulation, the amount of labor necessary to satisfactorily determine this point is not so formidable as it would at first appear. All anæsthetics certainly do depress the sensory nerves or centres, and especially so the cerebral centres. It is therefore obvious that we cannot hope for a preparation of this class which will not have a tendency to cause death by overwhelming certain vital portions of the nervous system and thus secondarily causing asphyxia or shock; yet the warning of asphyxia is generally so apparent that a fatal result can be avoided. But, on the other hand, where we have a compound which exerts an independent depressant action on the heart besides, we have a double danger to deal with; and that the large majority of deaths following the use of chloroform bichloride of methylene were due either to a paralysis of the heart alone or to secondary results because of such a depression, by which the already depressed nervous centres are further depressed or paralyzed on account of an inefficient supply of blood, must be apparent; and, while it is practically out of the question to even hope for an anæsthetic which will not cause death by paralyzing the nervous centres and thus causing shock or asphyxia, our one hope still lies in the effort of avoiding those preparations which decidedly depress the heart and which past experience has taught to be invariably dangerous, and of obtaining a compound devoid of this dangerous quality.

In the present investigation three modes of giving the ethylene bichloride were employed: 1st, by inhalation by means of a Woulfe bottle, by which method the air which the animal inhaled was compelled to pass through the bottle having in the bottom either the ethylene alone or numerous pieces of sponge saturated with it, the tube for the entrance of the air running almost to the bottom of the bottle, and the exit-tube being very short and merely extending to the bottom of the cork, so that the air which the animal breathed was always more or less saturated with the ether; 2d, by inhalation from a muslin cone held closely over the tracheal tube or nostrils; 3d, by intravenous injection.

General Action.—In normal animals, and when administered by the use of the usual muslin or linen cone, there are, as with most anæsthetics, three distinct stages,—excitant, anæsthesia, and profound narcosis. Here we have the struggles, general symptoms of intoxication, blunted sensibility and consciousness, a quickened pulse and accelerated respirations. Consciousness, sensibility, volun-

tary motion, and reflex action become rapidly annulled; the animal lies perfectly relaxed, and is thoroughly anæsthetized. If the inhalation is persisted in, profound narcosis rapidly supervenes, the pulse and respirations fail, and death ensues from a failure of the latter. The pupils may at first be dilated, but are afterwards contracted, and the further the anæsthetization is pushed the more fully they become so, unless it be in the last of the profound narcosis stages, when, preceding death, they have been observed occasionally to become dilated. Sensibility is invariably lost before motion, and I have almost unexceptionally seen muscular movements occur—not infrequently like clonic convulsions—after the complete abolition of ocular reflexes. It also appeared that the central functions were more seriously affected before other parts of the system.

Early in my experiments I learned that in order to know whether an animal was completely anæsthetized it was not necessary to consult the conjunctiva, but merely to watch the respirations, for just so soon as they became very frequent the animal was either anæsthetized or so near and rapidly approaching that condition that the inhaler could be removed and the operation proceeded with. If after the second stage is very pronounced the administration of the ethylene be continued, *the animal invariably dies from a failure of the respiration, and never in a single instance could I induce death by a stoppage of the heart by the inhalation of the vapor, no matter how concentrated the vapor was.*

The dose required to produce anæsthesia was about the same as chloroform, for the difference was so slight as to be unnoticeable.

(To be continued.)

POINTS IN PRACTICE BEARING UPON THE RELATIONSHIP OF TRUE OR MEMBRANOUS CROUP AND DIPHTHERIA.

BY JOHN J. BLACK, M.D.,

New Castle, Delaware.

COMPARATIVELY recent, yet growing wider from day to day, is the discussion in regard to the pathological identity of true or membranous croup and diphtheria; and the point to be decided by the medical profession is, Are ey pathologically one and the same affection, or are they, as heretofore generally supposed, different in their nature?

The distinctive name croup probably primarily referred to the peculiar changes of the voice in certain trains of laryngeal symptoms, and at the present time by the profession the word may be generally understood as referring to a genus of disease of which the various species, as spasmodic croup, catarrhal croup or catarrhal laryngitis, true or membranous croup, diphtheritic croup, or laryngo-tracheal diphtheria, etc., make up the aggregate.

Presuming that any practical results of experience bearing upon the discussion of this subject may prove of more or less interest to the profession at large, I am impelled to give a statement of the following circumstances surrounding cases to the point occurring in my own practice, without any particular note or comment:

On Friday, October 8, 1880, I was called to see two children (females), aged respectively 11 and 5 years, suffering, the messenger said, from croup.

I responded promptly, and was told by the mother that they had been under the care of an irregular practitioner, who had given up the cases as hopeless, and she requested me to take charge, hoping I might at least mitigate their terrible and incessant sufferings. Upon inquiry, I found that the oldest child was in the sixth day of the disease, and the youngest in the third day. The oldest appeared almost moribund, and was nearly unconscious from the accumulation of carbonic acid in the blood, and her great suffering appeared to be drawing to a close. The youngest was beginning to suffer the horrors of laryngeal obstruction, but yet appeared to retain full strength and activity. I examined these cases thoroughly, and could find no traces of diphtheritic membrane in its usual haunts, nor did they in any way present the well-known asthenic symptoms of well-marked diphtheria,—symptoms which had unfortunately been presented to me too often in the past year to mistake. Barring the laryngeal symptoms, the youngest child was robust and strong, and, from what I could learn of the elder, she had been equally so until a short time before I saw her. For the elder child I ordered milk and brandy to be pushed to the utmost verge of possibility, doubting that any effectual quantity could be gotten into her, and for the

younger such remedies as appeared to me best, not omitting the sheet-anchors in these affections,—food and stimulation, and vaporizations locally. Upon visiting the cases early the next morning, I was surprised to find the older child not only living, but really, under the circumstances, much improved by the treatment instituted, and for the first time I commenced to entertain an idea of helping her. Her pulse had changed for the better,—for, indeed, before she had been almost, if not quite, pulseless,—her temperature inclined to decrease, and she was entirely conscious, and, of course, with this state of affairs the effects of laryngeal stenosis were more marked.

There was no albumen in the urine in either of these cases by Heller's test, but mixed urates existed in great excess, and illustrated, better than in any cases I had ever met, the necessity of guarding against the mistake of assuming them to be albumen, when the more insoluble of the urates are thrown down after adding the acid. Heat applied here dissipated the ring entirely. In examining the urine in diphtheritic cases I would insist upon great care on this point, as the excess of urates in the urine so often present may readily be mistaken for albumen. If cases which are generally recognized as diphtheria and are generally or always asthenic in their nature, and cases which are generally recognized as membranous croup and are generally or always sthenic in their nature, should be proved to be one and the same disease, arising from one common cause, the presence of albumen in the urine in the one set of cases occurring far more frequently than in the other may be caused by the greater excess of parasites in the blood in the former or asthenic cases, nephritis, as has been suggested, being set up by the passage of the bacteria of the blood through the kidneys.

The peculiar surroundings of these cases, professionally considered, induced me to take an especial interest in them, and I requested my friends Drs. D. F. Woods, of Philadelphia, and David Stewart, Jr., of New Castle, to see the cases with me. Dr. Stewart had already pronounced the cases membranous croup, as so understood by the profession at large; and when this diagnosis was confirmed in every way, after a very careful examination, by a diagnostician so well and generally known to the profession as Dr. Woods, I felt abundantly strengthened in my first impressions.

The younger child was now beginning to suffer all the horrors of laryngeal obstruction, and the elder offered but one hope, and that only as to euthanasia apparently: so, having with some difficulty obtained the necessary consent of the family, and with the advice and full approbation of Drs. Woods and Stewart, and aided by their very valuable assistance and advice, I performed tracheotomy, first on the oldest child, and next on the youngest, introducing the tubes in each case immediately after the operation, the immediate results of which in both cases were all that any surgeon could desire. The oldest child died on the third day from exhaustion, her life prolonged three days at least by the operation. The younger child died on the sixth day. Acute inflammatory œdema of the tissues of the neck supervened on the third day, which tended greatly to prevent a favorable issue. There was no tendency to the formation of membrane on the cut surfaces in either case. One great balm to the unsuccessful termination was that euthanasia was accomplished in both cases.

In October, 1878, from the effects of the great storm of that month, the lowlands adjacent to this city were overflowed from the breaking of the levee guarding these lowlands from the encroachments of the Delaware River. This levee was repaired and all of the water shut off by June, 1879, following. In the month of August, 1879, a serious epidemic of diphtheria broke out in the city of New Castle, and raged with great violence until March, 1880, when it ceased, only a few sporadic cases having occurred since. With this exception, no place rapidly extending as this city is could have been more free from epidemic or contagious diseases. The house in which the cases whose history I have narrated occurred is situated on Vine Street, which situation compares favorably as to healthfulness with other parts of the city. The front room of the house had been used as a meat-market in 1879, and the man occupying it during the diphtheritic epidemic of that year lost two children by that disease. I did not attend the cases myself, but from what I could learn they died from laryngeal obstruction.

The meat-market remained in the house until March, 1880, when the mother of

the children whose cases I have related moved in, and the premises were thoroughly cleansed and purified. This woman kept a trimming-store, and the surroundings here, as to health and cleanliness, were apparently good, except the cellar, which needed and received prompt attention. Two days before the youngest of these little girls died, an older sister in the same house developed a well-marked case of true diphtheria, involving the throat generally. The case responded to treatment, and fortunately no laryngeal symptoms were developed. In this case there was a small amount of albumen in the urine. This case showed the presence of the diphtheritic poison in the premises, and pointed out a cause for the laryngeal cases which ended so disastrously and gave to me a clear illustration of the coexistence of well-marked cases of membranous croup and diphtheria, and, I assure the reader, have caused me to pause and consider, as I have never considered before, whether or not true croup and diphtheria have not one and the same cause and are not one and the same disease.

April 21, 1881.

AN IMPROVED DIACHYLON OINTMENT.

BY LOUIS A. DUHRING, M.D.,

Professor of Skin Diseases in the Hospital of the University of Pennsylvania.

PERMIT me to call attention to an improved diachylon ointment. According to my experience, very few pharmacists are able to furnish a satisfactory ointment made after the several published formulæ. In the second edition of my Treatise on Diseases of the Skin, page 186, I give the original formula of Prof. Hebra, together with full and explicit directions for its manufacture, derived from personal experience, and, as there stated, a valuable ointment may with care thus be obtained. In the hands, however, of pharmacists unacquainted with the details of its preparation, the bare formula is of little value, as the result will usually prove.

Recently Mr. M. Eisner, manager of the Cramer & Small Pharmacy, in Race Street below Fourth Street, has on several occasions furnished me with an ointment of such uniformly superior quality that I have been led to investigate his method of manufacture.

He informs me that he has always experienced much difficulty in preparing and also in keeping diachylon ointment made according to Hebra's directions. After considerable experimenting, he has arrived at the following formula, which furnishes an ointment containing a definite amount of oxide of lead, which, with the use of litharge, cannot be estimated. One part of freshly-precipitated (from acetate of lead) pure white hydro-oxide of lead is rubbed with two parts of water, and mixed well with six parts of the best Lucca olive oil. It should be stirred for about two hours over a hot-water bath near the boiling-point, and cooled with constant stirring until the proper consistence is obtained. While cooling, a drachm of oil of lavender to the half-pound of ointment is added.

This ointment, according to Mr. Eisner, contains the oleo-stearate of lead, has a neutral reaction, and can be kept in good condition for some time. It is a smooth, whitish, elegant preparation, and is altogether more desirable than that made according to the original formula.

TRANSLATIONS.

FATTY EMBOLISM. — C. Sepp (*Cbl. f. Chir.*, 1881, p. 135; from *Inaug. Diss.*, *Leyden*, 1880) comes to the conclusion that the existence of fatty emboli in living warm-blooded animals has not been proved. The fact that fat-collections have been observed after death in the capillaries does not prove that they occur during life. Grohé thought that the disturbance of the circulation during the death-agony might drive together the finest particles of fat, and give rise to the emboli found after death. Though Sepp admits that the difficulty of emulsifying fat with blood may lead to the collection of distinct oil-globules smaller than the capillaries, and thus support Grohé's views, yet he believes that the occurrence of fatty emboli in living animals is doubtful, for the following reasons.

Emboli can only form when the blood-pressure is insufficient to overcome the resistance met with by the fat-globules in the capillaries. This resistance is chiefly dependent upon the cohesiveness of the fat-corpuscles, which is diminished when the temperature increases. If, then, fatty emboli are found in cold-blooded animals,

that is no reason why they should be found in warm-blooded ones, where not only is the temperature higher, but the blood-pressure greater. The occurrence of fatty emboli after death proves nothing, since these occur during the death-struggle, when the blood-pressure is diminished.

Sepp experimented on rabbits, injecting oil into the lingual artery, and then examining the retinal capillaries, but failed to find any emboli. Müller, in 1860, reported a case where a fatty embolus was found in the retinal vein of a patient suffering from renal disease; but, as this statement is unsupported by similar cases, it must be concluded that the occurrence of fatty emboli in warm-blooded animals is very doubtful.

In addition to the above-discussed question, Sepp reports that he has succeeded, by making post-mortem injections into the pleural cavity, in producing emboli. He finds, also, that vaseline is very rapidly absorbed and excreted; finally, that, almost without exception, the temperature of the animal experimented upon became lowered immediately after the operation.

In conclusion, Sepp made the following experiments in the absorption of fat in inflammation: 1. The hind leg of a dog was rendered bloodless by Esmarch's bandage, and was then dipped for a few moments in water of about 70° C. Five days later, the dog, having showed oil in his urine, was killed by strangulation. Examination showed diffuse fatty emboli in the lungs and kidneys. 2. A rabbit had its hind leg merely enveloped in an elastic bandage. Twenty-four hours later, he was killed, when fatty emboli were found in the lungs. 3. The same experiment was tried, only the animal was killed with carbonic oxide gas. Several fatty emboli were found in the lungs and kidneys.

The Question of Mobilization or Immobilization of Diseased Articulations.—Verneuil (*Cbl. f. Chir.*, No. 10, 1881; from *Bull. de la Société de Chirurgie*) states four circumstances under which, usually, artificial mobilization of a joint is sought: 1, to overcome an existent anchylosis; 2, to improve an imperfect or inconvenient position; 3, to increase the mobility of a joint as yet not completely anchylosed; 4, to prevent anchylosis.

In order to establish his position (favorable to immobilization), in opposition to the prevailing custom, Verneuil begins by asserting that no single case exists in science which goes to prove that a long-continued immobilization of a *sound* joint can cause anchylosis. On the other hand, numerous cases are on record where healthy joints have rapidly gained their normal mobility a very short time after being released from long-continued immobilization. The conclusion is that healthy joints do not become anchylosed even after long-continued rest. How is it with diseased joints?

Granted we desire to give rise to anchylosis, what do we do? Fix the joint? Not at all. We endeavor to excite purulent inflammation of the articular cartilages. An "anchylophobist" must now immobilize the joint, to prevent anchylosis. But experience has shown that immobilization is the surest way to prevent inflammation, and the danger of anchylosis increases with the intensity and duration of the inflammation. Thus, anchylosis is here best prevented by keeping the joint quiet. Nature itself shows this; for the neighboring muscles are found contracted, or at least, as Verneuil expresses it, in a state of extreme vigilance. What justifies us, therefore, in blaming the immobilization in this case, and not much rather the joint-affection, in case anchylosis occurs? Conclusion: diseased joints do not become anchylotic by immobilization, but as a result of the peculiar form of inflammation and its deleterious effects.

Verneuil goes on to show that anchylosis is a much rarer result in the various joint-affections than is generally supposed, and that, on the contrary, too great anxiety and fear of anchylosis has led, especially in fractures near joints, to premature attempts at mobilization, with the result of doing more harm than good.

When anchylosis does occur, following long-continued immobilization, the cause is to be found either in the severity (or variety) of the inflammation (blennorrhagic arthritis, inflammation of the joint in osteo-myelitis,—occurring in the neighborhood of the epiphyses,—arthritis of pregnancy) or the position of the fractured fragments hindering the normal function (as in fractures into joints). In other cases, although stiffness may last for a while, yet in the course of time nature will restore the joint to its normal condition.

Acute Symptoms in Exophthalmic Goitre.—Dr. M. P. Merkelen (*La France Médicale*, 1881, p. 338) gives the case of a

woman who had been subject to exophthalmic goitre for six years, the disease following the usual type to within a month of her admission to the hospital, at which time she was attacked by acute symptoms following exposure to cold, for which she sought relief. On examination, the patient's face was congested; the thyroid was enlarged, especially in the left lobe, and throbbed violently, but with intermissions of five seconds, in accord with the pulse and heart. Exophthalmus was marked, without troubles of vision, however; the pupils were constantly dilated, and reacted imperfectly to the influence of light. There were also cardiac palpitations of such violence as to raise the left side of the thorax at each systole. No morbid sound on auscultation, but numerous irregularities. There occurred, in addition, epileptiform attacks in the face and limbs, chiefly of the right side, sometimes incomplete, sometimes abortive, sometimes complete, but without the cry or coma. When the attacks interrupted the patient in the middle of conversation, she took up the thread again after the attack just where it had been dropped. These convulsive attacks appeared to occur just after the prolonged intermissions of the heart and pulse, which sometimes, as has been said, lasted five seconds. They occurred every minute or every two minutes during the examination. Finally, general hyperæsthesia over the abdomen, with gurgling and the *tache méningitique*, was observed. The bowels were constipated, the urine albuminous. The patient was placed upon digitalis and bromide of potassium, with an aperient.

Within a few days marked amelioration in all the symptoms took place. The pulse fell to 90, and the patient appeared to be getting better, when a new group of symptoms manifested themselves,—an eruption of erythematous macules of the thyroid region and lower part of the face, with pain on touching the skin. The heart was decidedly dilated, and throbbed violently. There was marked hyperæsthesia over the abdomen and thighs. In the following days pains in the neck, disturbance of vision, and diminution of albumen in the urine were remarked. The pulse sank to 54–60. The patient slept little, and suffered from repeated epileptic attacks; the temperature rose to 104°, the tongue became dry, and there was diarrhœa and incontinence of urine, painful congestion of the liver, with jaundice, subcrepitant râles at the base of the left lung, with abundant expectoration. Gradually from this time the patient began to mend, and recovered her normal condition, and at the end of a week was able to leave the hospital. The treatment was essentially the same throughout, only that inunctions with ung. hydrarg. and dry-cupping were employed over the chest.

In remarking upon the peculiarities of this case, Dr. Merkelen suggests hyperæmia and irritation of the bulb as the probable cause of the convulsive attacks: this hyperæmia and irritation translated to the ganglia of origin of the pneumogastrics showed itself by the irregularities in the heart's action. The congestive troubles showing themselves in the albuminuria, the diarrhœa, the icterus, may all have been the result of bulbar influence. The happy effect of the treatment was manifest. Digitalis, indicated as a tonic to the vascular system, and as a regulator for the circulation, acted most effectively in arresting the irregular movements of the heart which were so threatening.

Multiplex Fibroma of the Lung.—Rindfleisch (*Virchow's Archiv*, Bd. lxxxi., 1880, p. 517) gives the case of a boy of 12 years who died in the hospital of chronic catarrhal trouble of the respiratory tract, without an exact diagnosis of his disease during life. One symptom in particular was very curious and doubtful, namely, the secretion and rejection of a considerable quantity of a clear yellow fluid which was mixed with the sputum. The only way of accounting for this morbid, lymph-like discharge was by the supposition of a lymphorrhœa pulmonum. The examination post mortem explained the lymphorrhœa, but in a very unexpected and peculiar way. The lungs were found bound to the costal pleura throughout their entire surface by leaves or layers of various thickness and tenacity, not connecting opposite portions of the pulmonic and costal surfaces by bands, as is usual, but like a sort of intermediate skin. On cutting open the lungs themselves, enlargement of the mediastinal glands was found, and in addition to this a number of small nodular masses, resembling the cheesy deposits of tuberculosis, were found scattered through the lung-tissue. On section, however, these were found to be true fibrous nodules, like those of fibroma molluscum of the skin,

having a cavity in the centre and numerous lymphatic vessels connected with the air-passages in such a way as to account for the peculiar fluid coughed up by the patient.

POTT'S DISEASE OF THE SPINE OF SYPHILITIC ORIGIN.—Prof. Alfred Fournier (*Annales de Dermatologie et de Syphiligraphie*, t. ii., No. 1, 1881, p. 19) gives a case of this affection which is, we believe, unique in the annals of medicine. For, although such cases have probably come under the notice of physicians, yet their origin has not been traced to a syphilitic source. Prof. Fournier's patient was a man, 56 years of age, a fine, robust figure, who declared he had never suffered a day's sickness in his life, but who showed signs of enfeebled health. He was emaciated, and so weak that he could scarcely walk, and he had quite lost his appetite. He complained also of pain in the lumbar region ("the kidneys") of a constant, dull character, but with occasional exacerbations of a few moments' duration, the pain then extending to the lower limbs.

Although this was all of which the patient complained, yet on examination various lesions, evidently of a syphilitic nature, were discovered. Thus, he had a syphilitic sarcocele, ten subcutaneous or muscular tumors, which from their appearance and history could only be gummatous, a gummatous ulcer of the great toe, a pigment spot upon the thigh, marking the seat of a recently healed ulcer, and marked atrophy of the muscles of the thigh.

The diagnosis of syphilis having been made, the appropriate treatment was directed, under the use of which the patient's external symptoms all improved; but his general condition grew worse from day to day. Later new symptoms showed themselves,—œdema of the lower limbs, hepatic pains, meteorism, ascites, pleuritic effusions, etc. His appetite failed, his strength left him, he became extremely emaciated, he fell into a condition of cachexia, and finally succumbed.

The post-mortem examination showed, in addition to the external lesions mentioned above, granular cirrhosis of the liver, with extreme peri-hepatitis enveloping the whole organ in a sort of husk of tough false membrane; characteristic cicatrices of the surface of the kidney; a gummatous deposit enveloping the fourth left lumbar nerve at its exit from the plexus, with degeneration of the nerve itself. In addition, there were multiple and considerable lesions of Pott's disease, affecting the lumbar spine chiefly in the third, fourth, and fifth vertebræ; denudations of the bones; thickening or destruction of the periosteal or ligamentous membranes; lesions of osteitis condensans, with purulent and caseous infiltration; almost complete destruction of one intervertebral fibro-cartilage; a vast cavity in the centre of the lumbar vertebral column; abscess by congestion in the thickness of the psoas on both sides, etc.

Of course, the most important question in this case was regarding the etiology of the Pott's disease. Was it a simple coincidence, a Pott's disease of the common variety superimposed upon a syphilitic constitution or concurrent with syphilitic disease, or was the Pott's disease itself of syphilitic origin?

Prof. Fournier decides in favor of the latter view: first, on account of the patient's advanced age, Pott's disease in the tubercular form being of extremely rare occurrence after youth; second, on account of the patient's previous robust health, the history of which, extending uninterruptedly through a lifetime, pointed away from the known antecedents of ordinary Pott's disease and in favor of a late diathetic infection of the system; third, the pathological concomitant, the various other unmistakably syphilitic lesions found, pointed to syphilis as a cause of the spinal affection; fourth, the appearance of the vertebral lesions themselves was characteristic,—their sharply defined outline, their clear yellow color, characteristic of the caseous gumma, and the regular hemi-circled configuration of the lesions composing the bony changes on the anterior aspect of a lumbar vertebra. Finally, at the origin of one of the conjugate ligaments of the lumbar column there was a tumor arising from the periosteum, which was recognized as a gumma, and the gummatous envelope of the nerves above mentioned showed signs of caseous degeneration in parts.

Prof. Fournier gives very full and careful notes of this important case, and also a report of the histological examination of the tumors. An excellent chromo-lithograph of a section of the diseased vertebræ accompanies the paper.

Affections of the Eye and Ear in Recurrent Fever.—The epidemic of recurrent fever which recently affected Königsberg has afforded Dr. Luchau (*Virchow's Archiv*, Bd. lxxxii. p. 18) the opportunity of observing and noting the occurrence of complications in the eye and ear. Out of one hundred cases of recurrent fever under Dr. Luchau's observation, thirteen cases of ear-disease were observed, nearly all occurring about the beginning of the fever, and all involving the middle ear, and usually inflammatory. The treatment recommended is as follows. When no suppuration has taken place, local phlebotomy is usually sufficient to allay the pain. When this is not enough, morphia may occasionally be employed. When suppuration has taken place, paracentesis of the membrana tympani is to be practised without delay. This little operation is painful for the moment, but soon gives great relief. The after-treatment consists in washing out the pus with a warm one per cent. solution of carbolic acid in water. A glass syringe should be used only in case of necessity: it does not give a strong enough jet to wash out thick pus. The cleansing of the tympanic cavity is best to be accomplished by Valsalva's method.

Of eye-affections Luchau observed six in his one hundred and eighty cases of recurrent fever. In three of these one-sided iritis occurred; in one case hypopion also supervened. All three cases were cured without evil after-effects. In two cases the eye-trouble took the form of neuritis optica. In another case inflammation of the optic nerve was observed in a second attack of fever. It is a curious fact that towards the end of the epidemic the number of the eye- and ear-troubles diminished in proportion to the diminution in the number of cases of recurrent fever.

Observations on the Occurrence of Bilharzia Hæmatobia.—Dr. John Wortabet, the well-known medical missionary, writing to Prof. Virchow (*Virchow's Archiv*, Bd. lxxxi. p. 578), says he has had lately under his care two cases presenting the following symptoms. 1. A small quantity of blood, from one to a few drops, voided after micturition, with a little strangury,—the constitution a little weakened, but otherwise not much affected. 2. The ova are always found in the clots; their form is more regular than is generally given in books; the embryo may be distinctly seen within the shell,—sometimes moving. 3. A free embryo may be occasionally seen with its cilia in action. From fresh specimens he has often succeeded in gently crushing the egg by pressing the glasses and thus liberating the embryo in a living state. 4. He once opened a vein in the arm, but found no ova in the blood.

Prof. Virchow, commenting on this note, says that Dr. Wortabet sent him at the same time some specimens of blood mingled with urine. Although extreme decomposition, with the formation of bacteria, had taken place, numerous ova of the bilharzia (distoma hæmatobium, v. Sieb) could be seen, with several embryos.

Physiological and Therapeutic Influence of Bromide of Ethyl in Epilepsy and Hysteria.—Drs. Bourneville and D'Olier (*Le Progrès Méd.*, 1881, p. 228) have made a series of investigations on this subject, of which they give a résumé in their paper. Their conclusions are as follows. 1. Dilatation of the pupil at the beginning of the inhalation is not constant. 2. Complete muscular relaxation is exceptional. 3. Anæsthesia is produced in varied degrees, dependent upon the idiosyncrasy of the patient. 4. The temperature, the secretions, and the general condition of the patient do not appear to undergo any modification. 5. The pulse and respiration are slightly accelerated. 6. More or less marked trembling of the limbs may be produced during inhalation, but this does not persist any longer. 7. Hysterical attacks are generally easily arrested by bromide of ethyl. 8. Attacks of epilepsy may sometimes be arrested by giving the medicine from the tonic period; most frequently inhalation is of no benefit. 9. In epilepsy the regular use of bromide of ethyl, administered in daily inhalations during a period of one or two months, diminishes very notably the frequency of the attacks.

University of Maryland.—Dr. I. Edmondson Atkinson has been elected Professor of Pathology in this school. He still retains the Clinical Professorship of Dermatology, previously held by him. Prof. Louis McLane Tiffany has been elected Professor of Surgery in the University of Maryland, Baltimore, *vice* Christopher Johnston, made Emeritus Professor.—*New York Med. Record.*

EDITORIAL.

THE UNITED STATES NAVAL MEDICAL SERVICE.

IT is probable that there is no medical government service in the world the requirements for admission to which are more severe than is the ordeal through which the medical candidate for naval honors must pass in this country. We are credibly informed that twelve aspirants have been before the examining board now in session without one having succeeded. So far as a good deal of experience teaches us, we should say that the standard is even higher for the navy than it is for the army. Most of our readers will no doubt agree with us, however, that when once in the navy a physician almost always disappears entirely from public sight, whereas in the army not rarely he rises to a first rank among scientists. The doings of the medical staff of the United States army are the talk of the world; the acts of the medical staff of the navy, what *are* they? A few reports lying upon book-shelves,—pitiful pamphlets alongside the invaluable tomes that have come from the Surgeon-General's Office at Washington.

Not only is this true of medical works proper, but also of scientific publications other than medical. Where is the Dr. Coues of the navy? Yet the abundant leisure, the months of floating in the tropics, the wide travel, afford both stimulant and opportunity for natural history research.

There must be some especial reason for these things. Is it that salt air is a veritable lotus-flower, soothing into an irresistible indolence him who breathes its miasm? Or is it because there is something faulty in the organization of the service itself? It may not be for a civilian to speak lightly of, or even to attempt to understand, the intricacies of military discipline, but is it not possible that general principles and common sense are applicable to men in uniform and to governmental organizations as well as to men in plain clothes and to corporate or private undertakings? How long would any business enterprise thrive whose management was changed every year or two?

The Surgeon-General of the army holds his position for years securely; the chief of the naval bureau clings most insecurely to his place for four years, or more frequently drops from his perch in a year or two, as helpless as a three-toed sloth when a rifle-ball or a storm-wind cuts the branch to which he has been attached. Unfortunately, the position as the medical chief of the navy gives to its occupant a special rank, which when once attained is forever held. The appointment nominally is for four years; but, in fact, so soon as a man is fairly in he begins to think, "I cannot stay here long enough to personally impress the service. My friend Jones wishes to be admiral, commodore, commandant [or whatever the rank is]. I'll get out, and let him in." Or friend Jones says to himself, "My friend Smith is now in; he can't get anything more by staying in, and I can get a good deal by getting him out: so out he shall come at the end of his term, if not before." Jones is aided by Jones second, Jones third, and so on to the fourth or fifth generation, who see Mecca looming in the distance, and have hopes. No one thinks of the service, much less of the profession, and in the heat of personal struggle science and the scientist are lost in the limbo of the uncared-for.

At present the chief of the naval bureau is a man well known to the profession by his writings, though we doubt if any of

our readers know that he is chief of the naval bureau. Surgeon Wales, of course, has scientific sympathies, and if he were permanently located in his place, we are convinced, would bring the service into repute by affording encouragement and facilities for work. Jones would like him out; but cannot the profession appeal to Jones to sink immediate personal interest for the general good, and at least wait his turn? The recent decision of the United States Supreme Court in regard to military affairs may be law, but seems to us extremely unfortunate for the government, as opening a door for the entrance into the military service of that system which has debauched the civil service of the country. It has been hitherto held that no commissioned officer could be discharged from the service save only through a court-martial or by act of Congress. A certain naval chaplain became crazy and sent in his resignation. It was accepted, and a successor nominated, and confirmed by the Senate. By and by chaplain No. 1 recovered his reason, and was astonished to find himself out of the service. He proved to the court that he was insane when his resignation was written, and that therefore he had not legally resigned, but was still entitled to rank and emoluments. The court, however, decided that the appointing power under the Constitution carries the dismissing power, and that if the President nominate a person for a military or civil position, and the Senate confirm, the joint act removes by presumption the previous holder of the office. The poor chaplain found himself, therefore, hopelessly shivering in the cold blasts of official and permanent dismissal. It is readily seen that under this decision the chief of the naval medical bureau has his hands full in watching the President, the Senate, and his own subordinates. Is it not possible for the American Medical Association to represent this matter by committee to Congress in such a way as shall lead to good?

THE American Laryngological Association will hold its annual meeting in the hall of the College of Physicians, May 9, 10, and 11. The profession is cordially invited to attend.

CORRESPONDENCE.

LONDON LETTER.

IN my letter two months back I made some remarks about the Royal College of Physicians of London, pointing out that, though it guaranteed the conduct of its Fellows and members, it had failed to exercise any inhibitory control over Sir William Gull when disposed to take his own way. I said some things which several may have thought rather strong, but I have been told that they were not sufficiently vigorous for the occasion. Just after mailing the letter the following sentence occurred in the *Lancet*: "Unhappily, there is not the remotest probability of the dignified but lethargic corporation in Pall-Mall being aroused to healthy activity by example or remonstrance of any kind." This at least is vigorous enough to satisfy any critic. In the previous letter it was said the College was coming to evil days. It seems that this is a fact about which no mistake is possible.

Lord Beaconsfield, as is generally known, is an Oriental—a Hebrew, indeed—who has risen to place and honor, whose career has been meteoric, and who is apparently disappearing with a great display of fireworks. For some years past Lord Beaconsfield has reposed his professional confidence in one Dr. Kidd, a man of great repute in the city, a man in most extensive practice, but imbued with homœopathic proclivities. Consequently, when the earl's illness became very grave a consultation was deemed desirable. There was apparently no other person of homœopathic faith whose opinion was worth the taking, so it was left for the earl and his friends to call in one of the recognized leaders of the profession. The first choice fell upon Sir William Jenner, who met the request with a flat negative, like the straightforward man he is and always has been, holding the honor of the profession to be his first consideration. Then Dr. Quain was sought. At first he objected, but ultimately consented. Whether he knew or did not know that Sir William Jenner had been asked and had positively declined does not appear. It was an oversight if he was not told; but it may be well to give him the benefit of the doubt. "Was Lord Beaconsfield to die without assistance?" Well, seeing that his lordship knew or ought to have known that in placing himself under a homœopathic practitioner he was deliber-

ately cutting himself off from the advantage of consulting regular practitioners, he was only meeting the fate he had courted; he had made his choice; it was his own concern, and nobody else's. Probably he calculated upon a weak compliance, treating the medical profession with that contempt which is accorded to it by persons in his present position in life. Nothing could prove more incontestably what I have before written about the social position of the profession than this present story. It seems to have been taken as a matter of course that the profession would bow the knee to Baal when asked to do so.

Dr. Quain first said he "could not meet a homœopath under any circumstances." He was assured that the noble earl was treated not homœopathically, but "according to the regular practice of allopathy." Under this solvent Dr. Quain's scruples disappeared swiftly. The *Lancet* spoke out with no uncertain sound. It said, "Wide-spread astonishment and unfeigned regret have been occasioned by the announcement that Dr. Quain, an eminent physician of the orthodox school of scientific medicine, has been called in consultation at the bedside of the Earl of Beaconsfield, and consented to meet and act with Dr. Kidd, a reputed homœopath. The explanation offered is that Dr. Kidd had not been treating the noble lord on homœopathic principles, but 'according to the regular practice of allopathy,' whatever that may mean: and Dr. Quain, though he at first declined, having satisfied himself on this point and taken the advice of 'leading members' of the profession, was able to lay aside his scruples and even to persuade himself that he 'would not under the circumstances be justified in persisting in his refusal.' The question which first suggests itself, on receiving this account of the matter, will probably be, *Who* are the 'leading members' of the profession upon whose counsel Dr. Quain acted? It is not a little remarkable that no recent scandal has occurred or mistake has been committed by any prominent member of the profession without a similar expression of opinion from some unknown or unrecognized 'authority' lending countenance and giving approval to the wrong done."

The *British Medical Journal* the next week supplies the desired information. The counsellors were Sir George Burrows, Bart., ex-President, and Sir James Risdon Bennett, then actual President, of the College. Such were the advisers in this case. Subsequently the opinions of Sir Thomas Watson and Sir James Paget were asked,—after the thing was done. But the first two were the accessories before the fact, on whose advice Dr. Quain resolved to act against a well-recognized rule. These, then, are "the most prudent and experienced Fellows" according to the *British Medical Journal*. Little can be said for their prudence here; and as to their "experience," the comment of the *Lancet* is most suggestive. It seems a pity Dr. Quain did not ask some Fellow with a little more "moral backbone" than these two titled Fellows. As regards Sir James Risdon Bennett, as the then actual President of the College, it would have been easy for him to decline to give or express any opinion,—a course the "prudence" of which is palpable; but perhaps his "experience" went in another direction. Certain it is that these two counsellors gave advice which the profession, as a body, resents. The matter was brought before an extraordinary meeting of the College on the 11th instant by Dr. John Charles Bucknill, whose manliness and integrity are so well known and so widely recognized. "The President, after intimating that there could be no discussion on the matter, requested Dr. Quain to reply to Dr. Bucknill's question." Certainly this was a judicial attitude to assume with a vengeance. Sir William Jenner felt his conduct to be impugned by Dr. Quain's explanatory remarks, and "rose to make a personal explanation, assuring the President, who ruled that the matter could not be further debated, that he was not about to discuss Dr. Quain's action, but merely wished to inform the College that he had himself been asked, previously to Dr. Quain, to see Lord Beaconsfield in consultation, and that he had distinctly refused to do so; adding that if Dr. Quain's conduct met with the approval of the College his own deserved censure." This was manly and outspoken, and has commanded the unreserved approval of the profession. The outgoing President might rule, if he liked, that there could be no debate at the council meeting; but he cannot stifle the expression of opinion by an outraged profession outside that council-chamber. Perhaps such expression of opinion has as little weight with him in this matter as the opinions expressed a little time ago about his knighthood apparently had with him. Oligarchies are superior to outside opinion so long as their day lasts. But this recent procedure will tend to bring down the tumbling edifice which had previously begun to totter. A ruling body which acts in defiance of public opinion ought to foresee that its existence —as an authority in matters of opinion—is simply at stake. But foresight is not what they have been remarkable for: indeed, the *Lancet's* comment involves more than the accusation of mere want of foresight.

The imbroglio is a pretty one, certainly. Granting that Dr. Quain felt that some odium might attach to him, since "he might, in the event of a fatal result, be looked upon as contributing to his lordship's death." Well, and, if so, what then? He would have been sustained by his professional brethren, and have rowed in the same boat as Sir William Jenner. That Dr. Quain yielded to a temptation too much for his powers of resistance is certain, and that he met in consultation again and again a

homœopath is only too obvious. Dr. Kidd writes, "He communicated with me as to how I was treating the case, and, upon receiving my assurance that it was not homœopathically, he without hesitation visited the patient, thus fulfilling the spirit of that 'boast of the medical profession, that in the hour of sickness it recognizes only humanity in need of succor.' In this way Dr. Quain and I did work together without being agreed, nor did either sacrifice his convictions to effect the co-operation." (*British Medical Journal*, April 16.) This is a most remarkable epistle. The "without hesitation" is a new light upon Dr. Quain's conduct; but the last sentence is beyond my comprehension altogether. They co-operated "without being agreed,"—certainly this is a novel kind of medical consultation,—yet neither sacrificed his convictions! The entanglement is superhuman: certainly we all will await the result with the greatest interest. So far it is a case of "the further in the deeper."

The profession is in a state of tension. The *Lancet* and the *British Medical Journal* are in direct antagonism in the matter. The latter says, "Dr. Quain immediately went to Sir George Burrows, on whose wisdom and profound sense of what was due to the profession he could rely, *and from whom he had always experienced great and uniform kindness*" (the italics are mine). When the editor resorts to "talk" like this, it is virtually admitting that his advocacy is handicapped heavily. He goes on to say of Sir William Jenner, "The reason which he assigns in the circumstances is not valid for the purpose, and not pertinent to the case." That this remark is certainly most "impertinent" none will for a moment doubt. Dr. Quain's conduct he holds "was alike accordant with professional ethics and public duty." No one will attach much importance to the views of the editor of the *British Medical Journal* in the matter of "professional ethics and public duty." And his attitude in this affair will still further widen the gulf already existing betwixt him and a large section of the members of the Association. His advocacy, such as it is, is about the most damaging matter for those whom he defends that could happen. "Save me from my friends!" indeed, may each exclaim. There is a wide-spread and rapidly extending circle who do not think Mr. Abraham Ernest Hart the fittest man possible to represent the Association as editor of its journal, and his views expressed in the present matter will not tend to reconcile them. The bulk of the profession feel that the law not to meet homœopaths in consultation has been violated in a conspicuous instance. They know how a certain section of the public will seize upon this precedent as an excuse for putting pressure on lesser men, of which they will not be slow to avail themselves. Let us suppose a case. Morland is a small town, where there is a most important local gentleman resident who reposes confidence in homœopathy and is attended by a homœopathic practitioner. His life is an important one in the locality in which he resides. He is "in a condition of such serious illness and great debility as to make it impossible that he could give any continuous account of his present or past illnesses, and that there was no other person available who could furnish the information but D——," and a local practitioner is called in. The value of the patient's life is to be made the gauge of professional conduct. Yes; but if this had taken place, the local practitioner having availed himself of such advice from neighboring medical brethren as was at his disposal, what would the editor of the *British Medical Journal* have done? In all probability he would have become the strictest stickler for professional honor and public duty, and have denounced that unlucky local humanitarian with all the stage thunder he could command. At least, if he did not so act, a good many of us would be very particularly surprised. All that was necessary was the assurance that the patient had not been treated homœopathically, and the matter was settled. Of course this precedent will be used readily in other cases, and the local man who will not bow the knee to Baal will have to suffer for his convictions. That is the long and the short of it. Persons can play at "homœopathy," and when a serious emergency arises call in the services of the orthodox members of the profession by a quibble, just as Lord Beaconsfield did. Where is the unity of the profession then? Of course we can make all allowances for Mr. Hart's regard for the interests of this distinguished representative of the Semitic race; but really the interests of Aryans must not altogether be lost sight of. Both are aliens in blood, and there are those who do not approve or unquestioningly believe in the rule of aliens. The whole matter will have to be thoroughly investigated, and the position of the profession towards homœopathy, especially when prominent members of society are involved, must be settled; the sooner the better. That Dr. Quain felt keenly that to leave Lord Beaconsfield unseen and to Dr. Kidd singlehanded was rather hard, is probable enough. But then, granting this, it is just how to act in emergencies that laws are specially enacted for the guidance of the individual. Some new enactment is called for after this case. And when a new regulation is made it is to be sincerely hoped that the "leading members, the most prudent and experienced of the profession," will see their way to abide by it, if only to keep other and less eminent members of the profession out of awkward predicaments, instead of "leading" them into sloughs. What the body or bulk of the Fellows thought on the matter is best testified by the election of President at their meeting. Sir William Jenner had just made his personal

explanation; and what did the Fellows do? Out of one hundred and eight Fellows present, eighty-seven voted for Sir William Jenner: that was their action. Sir J. R. Bennett came next, with seven: that was what they thought of his advice as President of the College. Nothing could be more significant than this election of President, as to what the Fellows as a body thought of the matter. The outgoing President (Sir J. R. Bennett) said "he had no fear for the future of the College, which was representative of British medicine, and he urged that the way to maintain its reputation was by circumspection in the elections into the Fellowship." This is a remarkable expression of opinion, certainly. For the College has washed a deal of dirty linen during his Presidentship, and the dissatisfaction about the method of electing Fellows is greater than ever. Perhaps the clique who have ruled the roast in the councils of the College could be well spared in the interests of the profession, to make way for others whose ideas of professional conduct are higher and more in accordance with what the profession, as a body, think and uphold.

This little matter is coming before the public in the *Times*. All the time that it was believed that the leaders of the profession were loyal to it in their refusal to co-operate with homœopaths, it appears from one of these letters that a homœopath can say, "I myself was admitted to professional friendship by the leading physicians and surgeons of London." Who, in the name of wonder, are these "leading" personages who practise the conduct complained of by the *Lancet?* There must be men in positions of eminence whose conduct is in private very different and opposed to what is publicly believed of them. It is only too painfully clear that there are men standing high in the profession who do not deserve the position they have acquired, or the confidence of the profession; and when an ex-President of the College and an actual President could advise Dr. Quain as they did, it is high time they gave place to men, men in every sense of the word, like Sir William Jenner, who will probably institute a very different and less undesirable state of affairs. Beyond the scandal which the present imbroglio is occasioning, there exists the serious difficulty of what is to be the rule of the profession about meeting homœopaths in consultation. From the exultant tone of the homœopathic writers to the *Times*, it is abundantly clear that they think the present difficulty is of decided advantage to them. They are not only exultant, but quite disposed to take the regular profession to task for their shortcomings and their rejection of the tenets of Hahnemann. They glory in the fact that "the great names of Risdon Bennett, Burrows, Watson, and Paget" approve of Dr. Quain meeting Dr. Kidd. A distinction, however, must be drawn between opinions given "before" and "after" the act, and the honored names of Sir Thomas Watson and Sir James Paget are dragged into the matter to support the cause in a manner which can only occasion deep regret in the minds of the regular members of the profession. I have long spoken out frankly that the position of medicine in England is unworthy of it; and though this has exposed me to hostile criticism on the part of one of our leading journals, which expressed its disapprobation of my letter, I venture to think recent events justify my expressions and vindicate what I have written. I have too much faith in humanity generally and in the profession in particular to believe that the present unsatisfactory state of matters can exist much longer.

J. MILNER FOTHERGILL.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA ACADEMY OF SURGERY.

STATED MEETING OF APRIL 4, 1881.

President, DR. S. D. GROSS, in the Chair.

DR. JOS. C. HUTCHISON, of Brooklyn, New York, was introduced by the President, and read a paper on

THE TREATMENT OF HIP-JOINT DISEASE BY THE PHYSIOLOGICAL METHOD OF EXTENSION. (See p. 481).

After the reading of the paper the author requested that the Fellows should freely criticise the points advanced.

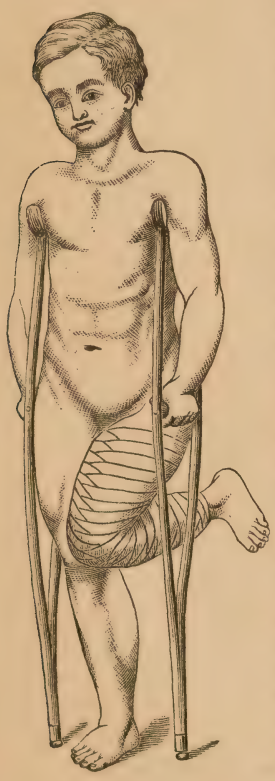
Dr. W. H. Pancoast thought the weight of the limb would be insufficient extension for treatment of cases where continued tonic muscular contraction had set in. It would not prevent in the later stages that muscular contraction which causes dislocation upward of the femur by rupturing the softened capsular ligament. He had seen two cases where the physiological method did not seem to be advantageous in the second stage of coxalgia; indeed, he did not think that extension of any kind was here indicated, because the greater the pull the greater is the contraction and grinding together of the joint-surfaces pressing against the inflamed synovial membrane. *Rest* is the great principle of treatment, and hence in his experience in the advanced second stage he had to do tenotomy and myotomy in many cases in order to obtain rest, which Physick had insisted upon as the important factor in treatment. Pain is developed by the squeezing and rubbing of the inflamed synovial membrane of the bones, due to the muscular contraction about the joint. Any form of extension is good in the first stage to keep the joint at rest, but when the muscles become rigidly contracted and stronger than the weight, the strain is to be taken off by

myotomy and tenotomy. Counter-irritation by blistering or the hot iron is then often useful in addition to the constitutional treatment. After a time support by some of the mechanical means of extension to allow exercise is needed. *Rest* is the desideratum: mechanical appliances alone, which do not give rest but cause irritation, will not suffice.

Dr. S. W. Gross did not believe that the indications were fulfilled by the method suggested. Spasmodic contraction of the muscles which act upon the joint was not observed when the patient was awake or when the brain was on the alert to guard against it. Hence, if he were to employ the method during the day, he would keep up extension at night by the weight and pulley. Although fixation of the joint was of the first importance, it would not do to depend upon the efforts of nature, since the constant contractions of the muscles not only intensify the inflammation present in the synovial membrane, the investing cartilages, and bones which enter into the composition of the hip, but force the head of the femur into an unnatural condition. After the signs of acute inflammation had subsided, he would, therefore, permit the patient to go about on crutches in the manner advised by Dr. Hutchison, but he would fix and keep the joint at rest by the posterior splint of Agnew, which extends from the middle of the leg to the middle of the back.

Dr. D. Hayes Agnew said that some statements in the paper met with his heartiest assent, but that he must dissent from others. As to apparatus supposed to separate the joint-surfaces, he believed that such a separation was not possible while the patient was going about walking on the affected limb. Certainly it was impossible in healthy joints, and seemed scarcely possible even in diseased articulations with softened ligamentous connections and intracapsular effusions. Thus far he agreed with Dr. Hutchison. He did not assent to intrusting the fixation of the joint to nature's efforts. To obtain the full benefit of rest it was necessary to relieve the muscles from all contraction. Muscular tension involves vascular tension; it attracts an undue amount of blood to the diseased part, and, therefore, intensifies the inflammation. He believed in immobilizing the joint by a posterior splint somewhat similar to the one employed by Thomas, of Liverpool, at the same time placing a high shoe on the foot of the sound limb and allowing the patient to move about on crutches. Extension, save in exceptional cases, he had not found necessary. Only let the muscles be assured that the joint is securely fixed, and all spasm and pain will cease. On the day of the meeting he had seen a case of coxalgia in a little girl, who was suffering great pain, which, however, disappeared on grasping the limb and holding it perfectly quiet. Another objection which holds good against the physiological method of Dr. Hutchison is the liability of the patient to sustain damage in the joint, when not supported by a splint, from falls to which all children are much exposed.

Dr. De F. Willard had tested the method in many cases since the first publication of Dr. Hutchison's views, but, while highly approving of the general plan, had made a modification, which he believed was needed because but one indication was fulfilled,—*i.e.*, *extension*,—while *fixation* was also necessary. The remark that we simply put the joint in a state of rest and let nature cure was wise; but it did not seem judicious to compel the muscles to fix the joint when they could accomplish it only by forcing an inflamed caput against a sensitive acetabulum. Walking on crutches was necessarily accompanied by a decided hip-swing at each step. Fixation could be readily secured by a moulded pasteboard, plaster of Paris, silicate of sodium, felt, or leather splint, which must go up upon the thorax as far as the sixth dorsal vertebra, because no splint fixes the hip-joint which does not rest against the ribs. With such fixation and the elevated shoe Dr. Willard had obtained good results. In his experience extension by a weight and pulley at right angles was necessary in the acute inflammatory cases of hip-joint disease. The impossibility of sitting down while encased in the dressing referred to could be easily obviated by the use of the locking and unlocking splint described by Dr. Willard in the *Philadelphia Medical Times*, November 6, 1880, which allows fixity or motion at will.



Dr. W. W. Keen had repeatedly tried the method, and thought it was admirable as far as *extension* was concerned; but, as the muscles are attached at an acute angle to the bone, they can produce *fixation* only by driving the femur firmly up against the acetabulum. He therefore advocated with the high shoe and crutches the use of a splint for fixation. He had recently seen a case of spasm of the tensor vaginæ femoris and other hip-muscles, due to phimosis, which simulated hip-joint disease. The muscular spasm remained absolute even under ether. Circumcision was performed, and in two weeks the child was well. Dr. Keen had used the high shoe and crutches in knee and ankle cases with great benefit, and thought the method one of the most useful devices of recent times.

Dr. Addinell Hewson referred to an instance in which, shortly after the introduction of ether, he had employed etherization and straightened a hip-joint which was supposed to be permanently anchylosed. No after-suffering resulted, and the patient was well in three weeks, having been treated with N. R. Smith's anterior splint and then a high shoe on the well side and a crutch on the other side. At the present time, after the lapse of

many years (nearly thirty), the man does not even require a cane in walking.

In answer to a question of Dr. S. W. Gross, Dr. Hewson said that he did not in any way wish it inferred that *he* had anticipated Dr. Hutchison's method: on the contrary, *his* purpose in putting the high heel on the foot of the *well* side was merely to prevent any pressure on the lame joints, and not, as Dr. Hutchison's, to effect extension by the weight of the limb (one-fifth of that of the body) there. His selection of Prof. N. R. Smith's anterior splint was to secure the complete rest of all the muscles at the hip, as was claimed by the Professor in his first account of that splint then published.

Dr. R. J. Levis had adopted the method, but not in the early or acute stage. Then he employed extension, as in fracture of the thigh, by means of a weight and pulley; subsequently the patients were allowed to walk on crutches with the high sole on the sound side. All his cases did well. It had occurred to him to use a simpler method, and one by which more fixation of the hip could be obtained if necessary. A diagram drawn upon the blackboard represented his idea, which consisted in lifting the foot of the diseased side from the ground by flexing the knee and keeping it flexed by a silicate of sodium splint, or encasement, which after being cut open in front was removable and readily reapplied by bandaging or by lacing it up. The patient then walked upon crutches without the necessity of the awkward elevation of the well side by a thickened sole. The flexed position is maintained during the day when the patient is walking on the crutches, but removed at night, when a weight extension apparatus may, if necessary, be applied. This method he preferred, because more convenient and less troublesome to the patient than the original method. He had shown at a previous meeting of the Academy two patients under this method of treatment. If complete fixation of the hip is desired, the silicate splint can be carried up on the pelvis. If the weight of the limb is not sufficient to overcome muscular spasm, sheet lead can be fastened in the folds of the bandage near the knee. His experience taught him that fully developed coxalgia cases are cured only after thorough muscular fixation and plastic adhesion, and rarely with the final result of much true motion in the coxo-femoral articulation.

Dr. W. H. Pancoast thought the pelvic fixation spoken of by Dr. Levis, if the stiffened bandage is carried up as high as the thorax, an improvement over the mere flexing of the knee as shown in the case presented at the former meeting, to which reference has been made. Cases in his opinion can be cured without anchylosis. Rest is to be insisted upon, but it cannot be obtained by fixation alone or extension alone; they must be used together, so as to give ease and rest. He preferred the term *rest* to the terms fixation and extension as now usually employed by surgeons. *Rest* to the diseased joint to prevent pressure on the inflamed synovial membrane is what should be enunciated, and what is taught by the pathology. Any one of these mechanical appliances which will give rest is beneficial. When the appliance will not give rest, and hence instead of giving the patient ease causes suffering, it must be removed, and other means employed. In the advanced second stage of the disease, extension will not give rest to the contracted muscles. If the peri-articular muscles are rigid while the patient is etherized, tenotomy or myotomy must be performed. If they are not rigid, the joint will bear extension. Last year he had seen a case brought from Liverpool wearing Thomas's splint, and was obliged to exsect the head of the bone because the disease had advanced to the third stage, as there was so much caries of the joint, with so great a discharge of pus, and consequent exhaustion. If it had been properly treated with Thomas's splint, and positive rest given in the first stage, he thought it would have done well. In the second stage spasm grinds the synovial membrane between the joint-surfaces, and if rest by extension or in bed is not gained, then tenotomy and myotomy are required. Counter-irritation may be necessary. He had examined a number of cases of joint-disease, and had never seen cartilages ulcerated or inflamed. Fine ether and vermilion injection failed to show a drop of the red injection in them. After amputation in the the living subject, he had seen cartilage exposed to the air and irritating fluids, and yet no inflammation was seen nor shown by the appearance of any blood-vessels in the cartilage. The cartilage became softened and of a dirty appearance, losing its pearly color, and was absorbed by the pulpy synovial membrane, but there was no evidence of inflammation in the cartilage. Synovial membrane becomes inflamed and excessively sen-

sitive, but articular cartilage has no sensation of pain, and cannot become inflamed, but macerates and is absorbed by the absorbent vessels in the synovial membrane.

Dr. S. D. Gross was taught very early in life that rest was the feature in the treatment of all inflammations. He had always insisted in his own teaching that rest was essential in joint-inflammation, and he believed that as fixation and extension give rest they were proper terms to use. He would have liked to hear the pathology of hip-joint disease discussed,—whether it was due to a constitutional vice or to ordinary causes apart from such a vice,—whether it was in its etiology constitutional or traumatic. Twenty-three years ago he had published in the *North American Medico-Chirurgical Review* the account of five cases of dissection after death of cases suffering from coxalgia. In every instance the patient was found to be tuberculous. He believed in the propriety of using early in the disease the actual cautery, as in similar affections of the ankle, knee, or vertebræ. He was satisfied from long and ample experience that it was a most important agent for arresting the morbid action before it had made any serious inroads in the articular structures. Combined with absolute rest of the affected joint, it left nothing to be desired so far as local treatment is concerned.

Dr. S. W. Gross remarked that there was a difference in the inflammatory process as exhibited in vascular and non-vascular structures. Active proliferation of the cells is the criterion of inflammation, and the gentleman who had denied that cartilage ever inflamed had, in his opinion, given an accurate description of the naked-eye appearances of that process.

Dr. Joseph C. Hutchison, in closing the discussion, remarked that the extension, by stretching the limb, prevents the spasm, which occurs especially at night, though it may occur in the daytime if the patient sleeps. If the patient be laid upon his back with the spine resting on a flat table, and the surgeon attempt to straighten the thigh, the back curves upward, showing that the pelvis moves with the femur because the joint is fixed by the contracted muscles. During the second stage it will be found that in nine-tenths of the cases the pelvis moves with the limb. This shows that the joint is kept at rest by the muscles: hence there is no need of uncomfortable appliances to enforce rest. If splints are adjusted with the idea of keeping up some extension while motion at the joint may take place, it will be found on careful watching that the patient in walking gets motion at the sacro-iliac joint and not at the hip. Plaster of Paris and the other splints mentioned certainly would fix the joint, but the muscles do this anyhow. Thomas's splint fulfils this indication, but is unnecessary. He has removed such a splint, and the patient has been comfortable without it. In the method advocated to-night the patient can sit down or can defecate with much greater ease and comfort than when wearing any of these fixing splints. The child is happier on the crutches, and just as comfortable as when lying in bed with weight extension. The physiological method does not compel the muscles to fix the joint, because they do this without compulsion.

JOHN B. ROBERTS, M.D.,
Recorder.

REVIEWS AND BOOK NOTICES.

THE PRINCIPLES AND PRACTICE OF SURGERY. By D. HAYES AGNEW, M.D., LL.D., Professor of Surgery in the Medical Department of the University of Pennsylvania. Vol. II. Philadelphia, J. B. Lippincott & Co., 1881.

Vol. I. of Dr. Agnew's work has been so long and so favorably known to the profession that any general introduction of the volume under consideration is unnecessary. The very flattering commendations of the medical press at home and abroad, the frequent references in surgical literature to the book and to the teachings of the author, and, above all, the practical test of daily consultation, which has demonstrated its value to those who possess it, have sufficed to establish the work as one of the few great recognized guides and authorities in surgical practice, and have rendered the advent of the second portion an occurrence of importance to the profession.

This volume contains thirteen chapters, beginning with a very exhaustive one upon the subject of *Dislocations*. The instructive plan has been followed here, wherever possible, of placing side by side illustrations representing, on the one hand, the anatomical position and relations of the displaced bone, on the other the resulting deformity. Especial attention is paid to the principles of surgical mechanics involved in the production of luxations and in the retention of the bone in its abnormal situation. The explanations of the manipulations employed in reduction are admirable in their clearness and their fulness of anatomical knowledge. In the reduction of recent luxations of the humerus where manipulation has failed, Dr. Agnew prefers the method of La Mothe,—*i.e.*, with the arm parallel with the side of the head and face. A table of anomalous dislocations of the femur is given, presenting in a concise form most of the recorded cases of supra- and infra-cotyloid and perineal luxations; also a table of the recorded cases of dislocations of the fourth, fifth, and sixth cervical vertebræ is given. The most important article in this chapter is, perhaps, that upon luxations of the hip, which are discussed at considerable length, the various positions of the head of the femur, the characteristic deformities, and

the different forms of apparatus employed in reduction being abundantly illustrated.

The following chapter is upon *Diseases of the Joints*, first treating of general conditions, as synovitis, anchylosis, strumous arthritis, etc., and then of diseases of special joints. Naturally the article on Coxalgia here predominates, and we would recommend it to critical readers as an illustration of the care and thoroughness with which the book has been written, and also of the happy combination of independence with conservatism which may be said to characterize the teachings and practice of the author. Here, as elsewhere, the phenomena of the disease are not merely enumerated, but are carefully explained, so that their remembrance by the student or practitioner becomes not an act of memorizing, but a rational association of cause and effect, of pathology and symptoms. Numerous tables are given enabling the reader to see at a glance the points of diagnostic difference between coxalgia and psoas abscess, Pott's disease, rheumatism, luxations, sacro-iliac disease, etc.

In regard to the very important and somewhat disputed point of the employment of splints in the treatment of this affection, the author thus unequivocally states his views: "I believe that the various mechanical appliances designed to combine extension with motion are in most instances highly prejudicial, tending to perpetuate inflammation and to favor suppuration, and thus either to prevent resolution of the arthritis or to delay anchylosis where that termination is inevitable. All the so-called walking splints, which allow the weight of the patient to rest on the affected limb, not only do not, in my judgment, fulfil the indications required in the treatment of coxalgia, but are at variance with all the principles involved in the management of the inflammation." The author protests against the extreme views which on the one hand deny the existence of strumous or scrofulous diseases of joints and refer all such cases to traumatic causes, or, on the other, affirm that in children such diseases invariably arise from diatheses of this nature. He believes that both causes are operative, the constitutional condition when present constituting a powerful predisposing element. Tables contrasting the differential symptoms of arthritis and pseudarthritis, hip and knee-joint disease, sciatica, spine disease, rheumatoid and strumous arthritis, are also given; and the description of the pathology and treatment of these ailments is most complete and accurate.

Excisions and *amputations* are next considered, and it is safe to say are nowhere better described, in some respects—especially in the fulness of the surgical anatomy and its application to practice—being superior to anything with which we are familiar in other systematic works on surgery. The illustrations here are profuse and uniformly good. Throughout this portion of the book the results of recorded cases are given with great care, and the average mortality invariably stated, that it may serve as a guide in the selection of an operation. The statistics of amputations are made up from a table of about fourteen thousand major operations, affording a far more extended basis for deductions than any hitherto compiled. The author's modification of the musculo-tegumentary method of amputation, described by him some years ago in the *Times*, is here given, with an illustrative cut which is perhaps the least instructive in this section. The article on *general considerations in regard to operations*, that on *accidents during and after operations*, and that on *complications following amputation* are worthy of careful perusal by every one engaged in surgical practice, as containing advice on many usually neglected points and embodying the results of years of large experience and careful observation. The chapter on *Anæsthetics* contains some very interesting sphygmographic tracings showing the relative influence of ether and of chloroform upon the heart. After mentioning the large number of recorded deaths from chloroform—which the author's researches have shown to be almost four hundred—and comparing them with the three doubtful cases of death from ether, he adds, "It seems to me that a surgeon who, in the face of such evidence, will continue to employ chloroform, assumes a tremendous responsibility. I hold that where two agents are open to choice, both capable of suspending sensibility and voluntary motion, we are bound, in justice to our patients, to select the safer. No man has any right to jeopardize unnecessarily the life of a fellow-being. Chloroform, except in the few cases where ether fails to produce decided anæsthesia, should be banished from surgical practice."

Shock, *Traumatic Fever*, *Burns*, *Erysipelas*, *Furuncle*, are all treated of carefully and with originality. In regard to the traditional treatment of carbuncle by the crucial incision, he states that for eighteen years he has rarely found it necessary to employ it, and believes that, as a rule, it neither hastens the cure nor lessens the suffering. To those surgeons who have witnessed the pain, the shock, and sometimes the serious hemorrhage which follow this operation, his dictum will not be unwelcome. The chapter on *Injuries and Diseases of the Genito-Urinary Organs* follows, and is very comprehensive, occupying three hundred pages of the volume, being indeed almost a treatise in itself. Cancer and fracture of the penis, wounds and lacerations of the urethra, urethral fever (which he believes to be a form of traumatic or surgical fever), urethral fistula, foreign bodies in the urethra (treated of with unusual fulness), gonorrhœa, with its sequelæ, diseases of the prostate

(a most instructive article), cystitis, hæmaturia, urinary incontinence, catheterism, varicocele, hydrocele, orchitis, spermatorrhœa, sterility, impotence, cancer of the kidney, and many lesser articles, make up this section, the many excellences of which want of space forbids us even to mention. We would, however, call especial attention to the articles on Vesical Calculus and on Urethral Stricture. In the diagnosis of the latter complaint, bulbous bougies are recommended as the best exploratory instruments, and steel bougies for the subsequent dilatation, which, it is most properly taught, should be always the first employed method of treatment. Failing in this, the author advises incision or internal urethrotomy, followed by dilatation. "The radical cure of stricture," he says, "I believe to be entirely beyond the reach of surgery, notwithstanding the immense and varied resources at her command."

After an elaborate study of the methods and results of removing stone from the bladder, he sums up his conclusions as follows:

1st. All cases of calculus occurring in infancy and childhood should be lithotomized. 2d. All cases occurring in adults in which the stone is soft, and not too large, should be treated by lithotrity. 3d. Even cases of hard stones, consisting chiefly of oxalate of lime (provided the concretion is small), and especially if there is any evidence of the existence of renal disease, should be treated by lithotrity. 4th. All cases not included in the above category are proper subjects for lithotomy. The particular method of the operation is to be determined by the magnitude of the calculus. 5th. Calculous patients suffering from serious structural disease of the kidneys are unsuited for either lithotomy or lithotrity, and should be content with "palliative treatment." A similar summary is given of the subject of stone in the female. The following quotation indicates the author's customary judicial frame of mind, even where he himself is concerned:

"It is very unwise for a surgeon to become too much elated by a long run of success. For several years—one year seven times—I cut patients for stone without the loss of a single case, when I became disposed to criticise the average mortality of the operation; but immediately afterwards I lost three cases in rapid succession."

He believes that the highest success would be obtained in lithotomy if the median operation were selected for small calculi, the lateral for stones of medium size, the bilateral for stones above the medium size, and the suprapubic for such as are of great magnitude.

A table of twenty-nine cases of nephrotomy shows fifty per cent. of recoveries,—a rather surprising result, when the gravity of the operation is considered.

The chapter on *Surgical Diseases of Women* embodies his well-known views on the treatment of vesico-vaginal fistula, and contains articles upon malposition and flexions of the uterus; dysmenorrhœa; uterine tumors; carcinoma; extirpation of the uterus; ovaritis; pelvic cellulitis; extra-uterine pregnancy; rupture of the uterus, and Cæsarean section. The author gives minute directions for the diagnosis and treatment of ovarian tumors; regarding the existence of the "ovarian cell" as yet undemonstrated; asserting that the tapping of such tumors, though rarely producing a permanent cure, is yet a harmless operation if properly performed; preferring the clamp for a long pedicle, the cautery or the carbolized ligature for a short one; and giving a table containing an analysis of 5153 cases of ovariotomy collected for this work. A table of 107 cases of Battey's operation is also given. In the chapter on *Surgical Diseases of the Spinal Region* the most important articles are those on lateral curvature and on Pott's disease. The treatment of the latter affection is most elaborately considered, and the various splints described. The felt splint the author has tried and disapproves of; and although in speaking of the plaster splint he pays a deserved tribute to Prof. Sayre, in saying that for its discovery "humanity owes him a debt of everlasting gratitude," yet he prefers a jacket made of leather and stiffened by thin strips of steel, a dressing which is lighter and far more durable.

The volume is concluded with a chapter on *Diseases of the Mouth*, which is in no respect inferior to the general standard of the work, and is quite sufficient in itself, without being supplemented by monographs, to serve as a guide upon these subjects to the working practitioner. It includes, somewhat comprehensively as regards its title, articles on glossitis, lingual tumors and cancers, caries of the teeth, odontalgia, dentigerous cysts (with a table of 36 cases), caries, necrosis, and tumors of the lower jaw, affections of the antrum, cleft palate, diseases of the tonsils, pharyngeal abscess, wounds and growths of the œsophagus, œsophagotomy (with a table of 36 cases), and directions for the evacuation of the stomach in emergencies.

The illustrations, which amount in the two volumes to nearly seventeen hundred, are excellent, often entirely new, and always selected with judgment. The index is unusually full and accurate, and the typography and general appearance of the volume are very creditable to the publishers.

It may be pardonable to say, in conclusion, that no one not personally acquainted with the author and with the harassing and incessant professional demands upon his time can conceive of the difficulties under which this work has been composed. That Dr. Agnew has been able, under these circumstances, to produce a book so comprehensive in its scope, so thorough in its details, so clearly expounding the principles of surgical science, and at the same time summarizing and recording

the results of an immense personal experience, is in the highest degree creditable to him, both as author and teacher.

No practitioner who needs—as who does not?—a conscientious and intelligent guide in emergencies or in difficult, obscure cases, or who wants a safe and reliable counsellor in the routine of daily practice, can afford to be without this latest and best production of American surgery. J. W. W.

SYPHILIS AND MARRIAGE. By ALFRED FOURNIER, Professeur à la Faculté de Médecine de Paris, etc. Translated by P. ALBERT MORROW, M.D. New York, D. Appleton & Co., 1881.

No question of more importance to the community presents itself to the thoughtful physician than that of the relations of syphilis to the public health, and no graver mistakes are committed in the practice of medicine than those of the untaught or misguided practitioner who undertakes to give advice upon the vital, yet delicate, question of the matrimonial relations of the syphilitic.

M. Fournier's eminence and great experience are sufficient *a priori* grounds for believing his book to be entitled to careful consideration; and a perusal serves to confirm this view. He has presented in a condensed but readable form the result of the acute and philosophic observation of a large number of cases, illustrating in detail, when necessary, and formulating his conclusions here and there throughout the book in terse and weighty sentences.

The book is divided into two main sections,—the first devoted to the period before marriage, when it becomes the physician's duty to determine whether or not marriage is at all permissible, and, if so, to fix the date; the second, considering the means of arresting or lessening the dangers produced by the marriage of syphilitics when that has already taken place without medical advice or in defiance of it.

The materials for producing such a work do not exist in this country, and could hardly have been obtained outside of the special hospitals of Paris, which have afforded the author a field which he has cultivated with rare originality. Syphilis by conception, by paternal or maternal heredity, time of specific treatment, personal dangers of the husband, dangers to society, social prophylaxis, are subjects the enumeration of which is sufficient to show the scope and interest of this interesting and valuable work, which removes a long-felt deficiency in medical literature. J. W. W.

STUDENTS' AIDS SERIES. G. P. Putnam's Sons. Part I.—SEMEIOLOGY. By J. MILNER FOTHERGILL.

An historian of our time has said, "The knowledge which a man can use is the only real knowledge,—the only knowledge which possesses growth and vitality, and converts itself into practical power. The rest hangs like dust about the brain, or dries like raindrops off the stones." So able an exponent of semeiology as the author could only dispense crumbs of golden thought; but our comment is that the fragments are too small to be of much practical utility. It is impossible to put some subjects in a nutshell.

The companion work, "Aids to Physical Diagnosis," by J. C. Thorowgood, is excellent, so far as the limit of sixty small pages will permit, and we like it better than many more pretentious works. E. T. B.

GLEANINGS FROM EXCHANGES.

THE CAUSES OF PRURITUS VULVÆ.—In a clinical lecture on this subject (*British Medical Journal*, vol. i., 1881, p. 327) Dr. Wiltshire mentions the animal and vegetable parasites as frequent local causes of this condition. Ascarides, pediculi, and acari are among the former, and certain low forms of vegetable life, as thrush fungus (*oïdium albicans*), among the latter. Among other local causes we have—1, diseases of the vulva (as vulvitis, abscess, carcinoma, oozing tumor, lupus, elephantiasis, etc.); 2, diseases of the urinary system (urethra, bladder, and kidneys); 3, vaginitis (gonorrhœal and other); 4, diseases of the uterus (metritis, endometritis, senile catarrh, cancer, fibroids, polypi, acrid discharges arising from the foregoing or occurring mainly in association with menstruation); 5, skin affections (eczema, ecthyma, herpes, urticaria, acne, etc.). As regards the latter, eczema may be associated with diabetes, producing terrible suffering, while urticaria suggests ovarian disease. Ecthymatous spots with ashen-gray bases may indicate grave cachexy (syphilitic?), while the herpetic vesicles are prone to crop out periodically in females of gouty parentage just before each menstrual period. A pustular form of acne is sometimes accompanied by troublesome itching. Venereal warts may excite itching.

Malignant disease of the uterus and upper part of the vagina may provoke itching in two ways: first, by acrid discharges; and secondly, reflexly,—the latter uncommonly. The same may be said of fibroids, polypi, sarcomata, etc. Dr. Wiltshire has known pruritus to exist for a long time apparently as a consequence of pelvic effusions, *e.g.*, hæmatocele, cellulitis, partly, perhaps, from venous obstruction and partly from implication of nervous structures. Some discharges from the womb are virulently acrid, and excite excoriation of the parts over which they flow. These are revealed by the speculum. Urethral and vesical affections—*e.g.*, vascular growths, stone, incontinence, etc.—are sometimes complicated by vulvar itching. Careful local investigation is therefore necessary; for, even when some general condition, as

diabetes, is present, the local condition may give valuable information.

Among general causes we find diabetes, pregnancy, gout (or lithiasis), syphilis, and pruritus senilis. Diabetes is not an uncommon cause, and vulvar pruritus may be one of the first symptoms which lead to its detection. Pregnant women are liable to a severe form of pruritus vulvæ, accompanied usually by an abundant creamy discharge. Sometimes aphthæ or erosions are seen upon the turgid labia or cervix, or there may be vaginitis granulosa. Most of the cases which Dr. Wiltshire has seen have been accompanied by extreme venous turgescence. Gouty pruritus is apt to be brought on by indulgence at the table or any diet which increases the deposit of lithates in the urine. Chancres and venereal warts (which last Dr. W. apparently considers syphilitic.—ED.) may provoke irritation. Pruritus senilis is often associated with general cutaneous hyperæsthesia. Klob says there are little elevations of the skin, like goose-flesh, consisting of growths analogous to tubercular formations, and giving rise to violent itching. These cases are grave. Some are amenable to the bromides used locally as well as internally. Arsenic and cod-liver oil are also indicated.

All forms of pruritus vulvæ are subject to periodical exacerbation. Some patients suffer only at night, after becoming warm in bed, experiencing comparative freedom during the day. All who menstruate are conscious of aggravation at that time. Stimulants, as a rule, exert an injurious effect. Sedentary occupations, piles, and hepatic disorders aggravate pruritus.

THE TREATMENT OF PRURITUS VULVÆ.—In a clinical lecture on the subject of vulvar pruritus, part of which we give above, Dr. Wiltshire (*Brit. Med. Jour.*, vol. i., 1881, p. 328) says that the first thing is to find, if possible, the cause. Extreme cleanliness must be enjoined. Demulcent washes are better than soap, unless carbolic or coal-tar soap be used; and usually even these are inadmissible. Almond meal, strong bran-water, decoction of rice, marsh-mallow, slippery elm, or fine oat-meal are suitable, especially the first, which, if pure, yields during use a marked odor of hydrocyanic acid and appears to soothe materially. When the pruritus is due to animal parasites, ointment of white precipitate, sulphur, or stavesacre speedily cures by destroying the insects and their ova. If nits persist about the pubic hairs, a lotion containing bichloride of mercury and acetic acid will dissolve them. Ascarides are destroyed by a carbolic lotion (1 to 60): general treatment, however, should be used, as iron, quinine, cod-liver oil, together with enemata of hamamelis, lime-water, iron, etc.

The vegetable parasites are treated by washes of borax, boracic acid, sulphurous acid, etc. Parasiticide lotions are certainly the most useful in the majority of cases, which points towards vegetable organisms as the commonest cause of the pruritus. The borax lotion should be of the strength of a drachm to five ounces of warm water, or stronger. Hydrocyanic acid, say ℥j of the dilute acid to water ℥x, or morphia (2 gr.), atropia (½ gr.), aconitia (½ gr.), or veratria (½ gr.) to the same amount. Infusion of tobacco (half an ounce to the pint) alone relieves some cases, and forms a good vehicle for borax or boracic acid. It is not well to use glycerin with the borax, as a rule, as it is apt, owing to its affinity for water, to aggravate the irritation. Strong solution of poppy is a good vehicle for borax. Chloral frequently does not suit. Ice suits some, very hot water others. In some cases ether spray might be tried. Ointments, if used, should be of non-rancid fats or vaseline. Two drachms of iodine (tincture?) in two ounces of elder-flower water sometimes answers. Electricity may afford relief in neurosal cases. Probably faradism would be the preferable form.

In simple vulvitis borax or carbolic-acid lotions relieve. An ointment of calomel or bismuth is also good. Malignant affections of the parts call for ablation, but where this is not practicable sedative applications (conium, opium, belladonna) alone are often all that we can employ.

Of course urethral caruncles, urethritis, vaginitis, etc., should receive thorough treatment. When there is congestion with loading of the portal circulation, a mercurial and saline purge is helpful. When eczema with fissure is present, a poultice made of the clot formed by adding two drachms of lead-water to ten ounces of new milk is most useful. Diabetes must of course be combated, and frequent ablutions with borax washes form a good local treatment. In wakefulness from diabetic pruritus, codeia in one-grain doses in pill is often useful. The bromides are also useful.

Pregnant women often suffer terribly. When *oïdium albicans* is present, sulphurous acid gives relief. A tablespoonful should be freshly mixed with half a pint of warm water, barley-water, or almond emulsion for each application. Chloroform locally, in liniment, ointment, lotion, or vapor, answers well occasionally; bichloride of mercury, gr. i–v, ad ℥viij mist. amygdalæ, gives relief in some cases. It should not be used when there is abrasion. Section of the pudic nerve has been suggested in desperate cases, but has never been practised.

MICRO-ORGANISMS IN SURGICAL DISEASES.—Dr. Alexander Ogston presents an elaborate report on this subject to the Scientific Grants Committee of the British Medical Association (*Brit. Med. Jour.*, vol. i., 1881, p. 369), in which he reaches the following conclusions. The organism most closely examined was the micrococcus, though others also are figured in

the drawings accompanying the report. In inflammation the results are summed up as follows. Cold abscesses contain no micro-organisms, and their pus is harmless. Acute and pyæmic abscesses always contain micrococci. Pus whose micrococci are killed by carbolic acid or high temperatures is harmless. Pus containing micrococci is resisted by animals if the dose be minute or if it be injected into the peritoneal cavity. Doses of one or two minims injected into the subcutaneous tissue may cause death by blood-poisoning, or may cause sphacelus of the site of injection, or may be resisted by an unusually insusceptible animal. As a general rule, such doses produce acute inflammation, accompanied by blood-poisoning and ending in abscess.

The results of observations on wounds and suppurations other than abscess are thus summed up by Dr. Ogston. Suppurating wounds contain micrococci, whose numbers and activity are proportionate to the intensity of the suppuration. Listerian dressings prevent micro-organisms from gaining access to wounds. Micrococci in wounds withstand most antiseptic applications. Where no micrococci are present in wounds, no pus is produced; the discharge is serous. Micrococci exist wherever pus occurs, save in chronic suppurations, such as cold abscess, chronic acne vulgaris (?), etc. Micrococci in man produce the same varying effects as in animals: they may produce blood-poisoning without suppuration; they may cause suppuration; or they may be resisted by strong individuals under favoring circumstances. Lastly, there are, possibly, micrococci which do not produce suppuration.

Cultivation experiments showed that micrococci do not produce putrefaction. They develop best when removed from the atmosphere. The facts adduced by Dr. Ogston prove that micrococci are able under suitable conditions to give rise to blood-poisoning, to acute inflammation, and to suppuration. Dr. Ogston adds, in conclusion, that it is not intended to be conveyed by anything which he has said that micrococcus is the only organism which produces inflammation and blood-poisoning. The other organisms are to be investigated in their turn, and much yet remains to be done, for the subject is only in its infancy.

MISCELLANY.

A Bold Piracy.—The following letter appeared in the *New York Medical Record* for April 2:

"Dr. Fancourt Barnes, M.R.C.P., Physician to several lying-in hospitals of London, has recently issued a 'German-English Medical Dictionary,' which has been imported and is offered for sale by Blakiston, of Philadelphia.

"After a careful examination I find that Dr. Barnes has copied nearly every one of my words, with their definitions; the latter in the same sequence and with the same punctuation. The few typographical and other errors which escaped correction in the first edition and remained in my plates have, in nearly every instance, been so faithfully copied as to appear ludicrous, were it not for the fact that this alone affords sufficient proof of a shameless piracy. In reading German it is necessary to know the genitive as well as the plural termination of the noun, and a verb may have an entirely different signification according to the auxiliary used. These I have given, but Dr. Barnes has erased them; occasionally he has neglected to do so, and then they have been copied by his printer. Dr. Barnes must have corrected his proof very carelessly, or he would have detected these inconsistencies, as well as many errors in spelling, misplaced and omitted *umlauts*, etc., not contained in my dictionary, and which must prove very confusing to the student. The Latin word for *or* is often used in my definitions. Dr. Barnes attempted to suppress this resemblance by substituting a comma for this word; his frequent failure to do so is significant. In the definitions where I have accidentally omitted a comma, where a semicolon has been wrongly used, where words closely related are separated by others which should appear earlier or later, etc., Dr. Barnes has carefully followed suit. In short, there is not a page in his book which does not reveal the fact that he has stolen my whole work, adding a very few medical words and a number of chemical and zoological terms which may be found in the ordinary German dictionaries. I do not find more than a score of my words omitted, and the two books contain the same number of pages.

"As stated in my preface, my dictionary is an original work, the result of many years of industrious research. The sale of such a book is necessarily limited; nevertheless I hoped soon to be able to issue a revised edition, containing several thousand more words. Though Dr. Barnes's book has not facilitated the reading of German medical writings, he has—unless discountenanced by the press and by the profession, as I have every reason to expect he will be—rendered my new edition impossible for many years. Respectfully,

"G. R. Cutter, M.D.

"312 Second Ave., New York, March 2, 1881."

A Curious Case of Assault and Battery by a Physician.—The case of Latter *vs.* Braddell and wife and Sutliffe has attracted some attention in English medical circles of late, and is worthy of note. The case was an action for "assault and battery," brought by a young woman, a domestic servant, against her master and mistress. The mistress, suspecting that her servant was *enceinte*, had subjected her against her will to ex-

amination by Mr. Sutliffe, a medical man, who was joined as a co-defendant in the action. The case was tried before several judges in succession, these "doctors," as is usual, disagreeing. The court of final appeal decided in favor of the defendants; but the case is a warning to medical men that they should be sure of the consent of their patients before proceeding to examine them at the request of a third party.

WHEN DOES THE DANGER OF INFECTION IN SCARLATINA CEASE?—Mr. John Simon (*Lancet*, vol. i., 1881, p. 146) says, "It is believed that the dispersion of contagious dust from the patient's skin is impeded by keeping his entire body (including limbs and head and face) constantly anointed with oil or other grease, and some practitioners also believe this treatment to be of advantage to the patient himself. When the patient's convalescence is complete, the final disinfection of his surface should be effected by warm baths (with abundant soap) taken on three or four successive days, till no trace of roughness of the skin remains. Not until this has been done, nor without the greatest care that the clothes are clean and free from infection, should the patient, however slight may have been the attack, be allowed to associate with persons susceptible of scarlatina."

A NEW instrument for the application of cotton to the larynx, os uteri, etc., has been devised, consisting of a stout probe nine inches long, terminating at one end in two sharp spirally-twisted prongs. The cotton is twisted into these, and if to be left in the cavity can be detached by a reverse movement.

ANOTHER VICTIM TO TOBACCO.—A medical exchange states that Melohiah, a Choctaw princess, died at Hoyt City, in the Indian Territory, the other day, at the great age of one hundred and fourteen years. She had thirteen great-great-grandchildren. She had been addicted to the inordinate use of tobacco for one hundred and five years.

NOTES AND QUERIES.

THE NEW YORK MEDICAL JOURNAL,
OFFICE OF THE EDITOR,
33 EAST 28TH STREET,
NEW YORK, May 1, 1881.

HORATIO C. WOOD, M.D.,
Editor of the *Philadelphia Medical Times:*

DEAR DOCTOR,—In the *Times* for April 23, 1881, I notice an abstract of Dr. W. C. Ayres's article on "Permanent Pictures on the Retina" credited to the *Medical Record*. The article really appeared in this *Journal*.

Yours very respectfully,
FRANK P. FOSTER.

EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

SIR,—In the report of my paper read before the Philadelphia County Medical Society that appeared in your issue of February 26 the word *card*-board appears as the substance from which the support is made. In answer to numerous inquiries, I desire to state that *tar*-board is what was suggested. It is in every way superior, dries hard, and retains the form well. It can be obtained from wholesale paper-houses.

Yours truly,
J. M. KEATING.

April 28, 1881.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM APRIL 17 TO APRIL 30, 1881.

SURGEONS J. H. JANEWAY and J. S. BILLINGS.—Directed to represent the Medical Department of the Army at the annual meeting of the American Medical Association to be held in Richmond, Va., on May 3, 1881. S. O. 96, A. G. O., April 27, 1881.

BACHE, D., MAJOR AND SURGEON.—Granted leave of absence for one month on Surgeon's certificate of disability, to take effect as soon as a medical officer reports for duty at Benicia Arsenal and Barracks. S. O. 62, Division of the Pacific and Department of California, April 16, 1881.

GREENLEAF, CHARLES R., MAJOR AND SURGEON.—To report to Superintendent-General, Recruiting Service, to conduct a detachment of recruits to Department of Dakota, and, on completion of this duty, to join his station (Fort Shaw, Montana Territory). S. O. 95, A. G. O., April 26, 1881.

MCCLELLAN, ELY, MAJOR AND SURGEON.—When relieved by Assistant-Surgeon Ebert, to repair to these Headquarters for assignment to duty. S. O. 44, Department of the Columbia, April 5, 1881.

BARTHOLF, JOHN H., CAPTAIN AND ASSISTANT-SURGEON.—When relieved by Assistant-Surgeon Spencer, to proceed to Fort Lapwai, Idaho, and report for assignment as medical officer of that post, relieving Assistant-Surgeon Ebert. S. O. 44, c. s., Department of the Columbia.

CRONKHITE, H. M., CAPTAIN AND ASSISTANT-SURGEON.—To proceed from Camp Sheridan to Fort McKinney, Wy., and report for duty at that post. Camp Sheridan to be discontinued May 1, 1881. G. O. 8, Department of the Platte, April 20, 1881.

HEIZMANN, CHARLES L., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Vancouver Barracks, and assigned to duty as Post-Surgeon at Fort Townsend, W.T. S. O. 44, c. s., Department of the Columbia.

AINSWORTH, F. C., CAPTAIN AND ASSISTANT-SURGEON.—Having reported at these Headquarters, will report to the Commanding Officer, Post of San Antonio, Tex., for temporary duty. S. O. 56, Department of Texas, April 11, 1881.

SPENCER, WILLIAM G., CAPTAIN AND ASSISTANT-SURGEON.—When relieved by Assistant-Surgeon Heizmann, to proceed to Fort Cœur d'Alene, Idaho, and report for assignment as Medical Officer of that post. S. O. 44, c. s., Department of the Columbia.

BIART, V., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—So much of par. 1, S. O. 205, September 24, 1880, from A. G. O., as relates to him is revoked. S. O. 94, A. G. O., April 25, 1881.

EBERT, R. G., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Instructions by telegraph of this date to proceed to Fort Lapwai, Idaho, and relieve Surgeon McClellan as Medical Officer of that post, temporarily, confirmed. When relieved by Assistant-Surgeon Bartholf, to rejoin proper station, Fort Walla Walla, W. T. S. O. 44, c. s., Department of the Columbia.

ARTHUR, WILLIAM H., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—To report in person to the Commanding Officer, Fort Sanders, Wy.T., for duty. S. O. 31, Department of the Platte, April 16, 1881.

BUSHNELL, G. E., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Fort Yates, D.T. S. O. 61, Department of Dakota, April 11, 1881.

WYETH, M. C., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Fort Meade, Dakota. S. O. 61, Department of Dakota, April 11, 1881.

PHILADELPHIA, MAY 21, 1881.

ORIGINAL COMMUNICATIONS.

CLINICAL NOTES RELATIVE TO PHYSICAL DIAGNOSIS.

Read before the Philadelphia County Medical Society, February 23, 1881,

BY EDWARD T. BRUEN, M.D.

THE subject-matter of the remarks I will offer to the members of the Society this evening is the outcome of some observations in the domain of physical diagnosis. I am inclined to think that in questions of diagnosis we are often as much puzzled from having forgotten or overlooked received explanations of the phenomena of disease as, on the other hand, from our failure very often to proceed on a logical method of clinical study. In the first part of my paper my remarks may illustrate the primary proposition.

In clinical study by means of physical diagnosis there is a tendency to exalt the importance of investigation by auscultation and percussion, because of their real primal importance, to the neglect of other methods. I propose, in what I shall say, to develop, in the first place, the method of inspection in the clinical study of pleural effusions, because I have remarked that while many cases present the acknowledged evidences of this condition, viz., flatness on percussion, absent or distantly blowing breathing, absent or intense but distant divocal resonance, abolished vocal fremitus, etc., yet with reference to one method of examination, viz., inspection of the chest, there are many exceptions to the received evidences as laid down in the works on this subject.

There are a number of cases of moderate pleural effusion demanding special treatment, possibly operative, which may remain unrecognized because inspection is not practised. But sometimes it is urged that no information rewards the observer, and the method may adduce misleading evidence. The proposition, however, is that the intelligent application of inspection as a method of diagnosis is capable of evolving important results.

Three physical signs are usually recognized by inspection in cases of pleural effusion,—viz., there will be an enlargement of the affected side, with rotund bulging of the chest and intercostal tissues, and abolished respiratory movements, so far as expansion and contraction are concerned, over the area of the effusion.

It is also well understood that above the level of fluid in cases of limited effusions the respiratory movements may be almost normal. There are, however, certain exceptional facts, of supreme importance, to which I would solicit attention. These facts are, first, that in cases of effusion, even when this almost fills the chest, an up-and-down movement of the ribs of the involved side will often occur. In addition to this, an actual in-and-out movement of the tissues of the interspaces will occur on the involved side synchronous with respiration; usually with inspiration a depression of the intercostal tissues occurs.* Dr. Alexander James has also called attention to some facts which I myself have often noticed,—viz., there is frequently no obliteration of the intercostal spaces, nor is there increase by measure of the affected side, but, further than this, the side of the chest supplementally active on respiration is most prominent.

To elucidate these facts, I would invoke your attention to the following thoughts. The above-named physical signs are most demonstrable, not in the acute or largest effusions, but rather in those of a subacute or more chronic type, in the lesser effusions and those undergoing absorption. What is the nature or composition of these effusions? In the *Medical Times and Gazette*, January 3, 1880, you can consult a paper by Dr. James, continued in two numbers, devoted to an analysis of the composition of Transudations and Exudations. He has shown that the density of pleural effusions is greatest as contrasted with abdominal, cerebral, or subcutaneous effusions, because the respiratory movements exert an enormous aspiratory force, predisposing to transudation into the pleural cavities as a relief to the overfilled capillaries when the circulation is in the least obstructed,—as, for instance, the hydrothorax which occurs in heart-disease or Bright's diseases, as well as in sero-inflammatory collections. Pulmonary aspiration, he continues, explains the greater density of peritoneal as contrasted with cellular effusions. But this is not the only cause of the density of pleural effusions. Hoppe-Seyler has shown that, in cases of

* Edinburgh Medical Journal, October, 1880.

ascites due to cirrhotic liver, the more the fluid increases in amount, the more concentrated does it become. This is owing to the fact that absorption is continually going on by means of the lymphatics and peripheral branches of the systemic veins; and as water is the constituent of the transudation which is absorbed in most abundance, the transudation is constantly becoming more concentrated. To illustrate the influence of the respiration on absorption, Dybkowsky has shown that if solutions of colored liquids are injected into the pleural cavity of living dogs, absorption rapidly takes place, but that this does not occur if the animals are killed immediately after the injection. He also found that the rapidity of absorption was increased *pari passu* with the activity of the respiratory movements. Now, in large effusions, when the pleural cavity is almost filled, the aspiratory power of the lungs is lessened; but we must note that the physical signs I alluded to are most marked in cases of encysted effusions, or in those of moderate quantity, of subacute or chronic type, and those undergoing absorption. In these cases, as the lungs do partially expand, the aspiratory influence must be regnant. But, before applying this fact, let me cite some remarks of Dr. Douglass Powell* in a paper entitled "Some Effects of Lung Elasticity in Health and Disease." He has therein demonstrated that enlargement of the chest in pulmonary emphysema is due to the fact that the excentric thoracic resilience is less and less opposed by the elasticity of the lungs as the emphysema increases. He refers to a fact demonstrated by Stokes, that in emphysema the interspaces deepen on inspiration, as, in fact, do all the soft parts. The interspaces are found on a level only in extreme cases, when the pulmonary elasticity is totally destroyed; it is in these cases alone that the tissues bulge on forced expiration. We realize the verity of this excentric thoracic resilience when we consider that it is this power, aided by intercostal muscular action, which maintains the expansion of the chest in quiet respiration, although the action of the diaphragm tends to draw the chest-walls inward. Now, applying these facts to the exceptional physical signs I described in the outset, I incline to think the reason why there is often no obliteration of the intercostal spaces is because the increased density of the fluid in the chest tends to decrease the bulk of the effusion; and the area it occupies is diminished the longer a moderate effusion persists, just as a jelly, when it forms, occupies a slightly smaller area than the fluid from which it was formed. But, more than this, I mentioned an in-and-out movement of the intercostal tissues, occurring during the presence of an effusion in the pleura, noticed over the location of effusion. During the time an effusion persists, the chest-walls are already bulged beyond a physiological position, and from this point, owing to inherent resilience, they tend outward at each inspiration; but the lung-elasticity is abrogated to a varying degree by the compression of the pulmonary tissues by the effusion. Thus it comes to pass that the state of the chest-walls resembles their condition in moderate emphysema; consequently, the pulmonary intercostal tissues are depressed on inspiration, and tend to puff out or return to their morbid physiological state during expiration, just as these tissues act in emphysema of the lungs. I incline to think this explanation adequate, when the state of the effusion and the variety of case in which this phenomenon exhibits itself are considered; for it must be remembered that this movement occurs when there is not enough movement of the thoracic walls to invite the action of the intercostal tissues.

There are two other explanations of the movement of the intercostal tissues during respiration worthy of notice,—viz., in the first place, the union of the pulmonary and costal pleura by adhesions; but the retraction of the tissues in this case would occur during expiration, not inspiration. More than this, I have proved by post-mortem to my classes that adhesions were not present in cases in which, during life, we had noticed pronounced movement. The tissues may retract in inspiration, in cases of pressure on some portion of the bronchial tree; but this pressure is, of course, readily determined. The greater enlargement of the non-affected side is to be explained, as I believe, by the fact that the vicariously-dilated lung-tissue has not sufficient elasticity to oppose the excentric resiliency of the chest-walls. On the affected side, the accumulation of fluid gives a more rotund appearance to the chest-walls; but, by measurement, the circumference is frequently less than the healthy side, although

* Medico-Chirurgical Transactions, vol. lix.

effusion is present; and this retraction is aided by the tendency of the chest-walls to retract, if unsupported from *within*.

Before closing this part of the subject, let me express the concurrence of my clinical experience with that of Dr. James in the statement that there is a very close association between empyema and increased circumference of the chest, and bulging of the intercostal spaces of the affected side; and, with him, I have observed in these cases that there is sometimes a unilateral œdema of the corresponding side of the trunk. He remarks, "In empyema, these signs are due to the more acute pleural inflammation, producing at the same time a greater amount of paralysis, or, possibly, inflammatory alterations, in the underlying intercostal tissues; and thus occurs greater intra-pleural tension through diminished absorption, resulting from an interference with the respiratory movements. The lymph-circulation in the intercostal spaces is dependent on the proper movements of the intercostal muscles, just as the circulation in the diaphragm is dependent on its movements. In this way, the lymphatic circulation is doubly disabled."

Yet, while concurring in the main, I think that the above condition of the interspaces may also indicate an effusion attended by serious structural alterations in the pleura, without the formation of pus, or a hemorrhagic effusion. I have twice found this sign present in cases of hemorrhagic effusion, as proved by paracentesis, so that we may not expect a simple serous effusion if the œdema, etc., is present.

As a sign of some value in empyema guiding us to the selection of a suitable spot for the operation of paracentesis, in cases of encysted effusion, I would mention a study of the vocal resonance. In these cases the vocal resonance is apt to be quite distinct all over the chest-surface, possibly because of the presence of the adhesions and thickened pleural tissues favoring conduction. I usually select a spot where the vocal resonance is more muffled. Testimony relative to the vocal resonance in these cases is somewhat various. The writer in the *Edinburgh Journal* attributes the increased vocal resonance above the line of a pleural effusion, not to condensation of the lung above the fluid, but because the waves of sound transmitted through the bronchial tubes to the effusion are reflected upward, and the ear appreciates the resonance physiologically diffused over the entire thoracic cavity. This increased resonance, he says, can be heard at any part of the chest above the effusion, in which he differs from Skoda, who locates it at the lower angle of the scapulæ, near the large bronchi, near the vertebræ, and above or below this line. Walsh agrees, but says it can be heard anteriorly above the effusion. Guttmann declares the clear bronchial vocal resonance is only heard where the dense lung-tissue touches the chest, usually between the vertebral column and the scapulæ. I am sure we hear it both anteriorly and posteriorly, as Walsh expresses it; but I would invoke especial notice to the fact that it is also often so distinctly heard over the effusion that the element of distance, or the muffled quality of the sound, is the only element to enable us to make correct inferences.

Pursuing my theme,—viz., clinical investigation,—I would next allude to what I would style the logical approach to the study of the fundamental evidence in the diagnosis of aortic aneurism. I feel that my experience of seven years' unremitting study in the Philadelphia Hospital, during which time I have noted sixty-nine cases of aortic aneurism and seen many cases not noted, entitles me to express an opinion as to the method of clinical study which has been most helpful to me. The various writers on physical diagnosis have always laid great emphasis on the various murmurs which are familiar to us under the synonyme "bruits." When these typical murmurs are present, of course the evidence is most materially strengthened, and, indeed, is often rendered conclusive. But many cases of aneurismal enlargement should, if possible, be diagnosticated in their incipiency, before the enlargement of the aorta, whether by sacculation or dilatation, presents the physical conditions for the development of murmur or a typical bruit. I exhibit to the Society some typical specimens to illustrate my proposition that bruit may be much modified, or absent, although decided arterial lesions may be present. The aneurismal sacs in two of the cases are completely filled, in one case by laminated clot, in the other case by a ball-shaped, non-laminated clot, so that very little or no blood could enter or leave the sacs, but flowed through an aorta of which the diameter was nearly normal. In one case

the tumor was so superficial that pressure upon it undoubtedly influenced the lumen of the aorta, and so murmur could be developed not present under ordinary conditions; but in neither was there any constant bruit or murmur, and yet in both these instances death resulted immediately from the presence of these enlargements. In the third specimen—viz., an aneurism of the trunk of the cœliac axis—the orifice communicating with the aorta is merely a button-hole slit sufficiently large to admit of the passage of a medium-sized almond, the orifice leading from the aorta into the sac being the dilated cœliac vessel. The point I wish to urge in connection with this specimen is that such an opening from the calibre of the aorta into an aneurism may permit so little blood to enter or leave the sac that no bruit character is imparted to the murmur, and a murmur, if present, may be trifling.

As a second illustration of my argument, I would invite a mental review of the many associated minor evidences (so called because not including bruit) of aneurism, as detailed in reports of clinical cases. I am at a loss how to condense this part of the subject into the limits proper on this occasion. Let me merely cite, as representative of many, two cases reported in the *Medical Times and Gazette*, January 31, 1880, under the care of Dr. Broadbent. In one of these cases, post-mortem revealed an aneurism "as large as a hen's egg, its anterior surface firmly adherent to the sternum, its posterior portion to the trachea; it contained some firm laminated clot, with considerable disease of the rest of the arch of the aorta and of the thoracic part of the vessel. . . . The indications of aneurism were obscure; the sac was not large enough to give rise to extensive dulness on percussion, the only evidence being the compression of the left innominate vein, producing engorgement of superficial veins on that side, and pulsatile movement of the trachea and larynx." Yet notice as I again quote from the history: "there was tenderness with decided wincing on percussion of the chest, especially on the sternum and epigastrium, with pain in the upper interscapular region." I note that this pain continued as a marked symptom till the death of the patient. The pain was increased by exertion, attended by dry cough (meaning pressure) and a throbbing feeling at the mid-sternum when he walked. Further, "food seemed to stick in the root of the neck, as though a round, hard ball was in the œsophagus, and often it would be returned just as it was when swallowed. There was loss of flesh; depreciation of nutrition had been continuous; there was some difference in the radial pulses, the right being weaker than the left when the arms were raised above the head." His family history embraced the following facts: mother died of cancer; patient had suffered from rheumatic fever, and had lived a life involving severe tests of his arterial system. "He had been a heavy beer-drinker, and had formerly a good deal of saddle-work in connection with stag-hounds." In this case the diagnosis was not made certain, apparently because a murmur was not present.

An analysis of a second case shows antecedents of patient to have been good, but his occupation was that of a coal-heaver; age, 30. Symptoms were, pain running down right arm, then cough, then swelling near the right shoulder, under the clavicle; also dyspnœa, which became extreme on exertion; moreover, effort increased the gravity of all the symptoms; at times the breathing became stridulous. There was cough, which increased relatively with the increase of the swelling near the shoulder; there was continued loss of flesh, but he retained a fair appetite; pulse on right side preceded the left; the left pulse and left carotid pulsation were very feeble. There was visible pulsation on the right side, extending over an area of two or three inches in front of the chest, just to the right of the median line, causing some heaving upward of the sternal end of the clavicle; but no bruit could be heard at any time while the case was under observation. Yet at the time there was no difficulty in making the diagnosis, because the associated symptoms were so unequivocal; but I read, "when the patient left the hospital, the symptoms had so much ameliorated, the diagnosis would have been difficult for a person seeing the patient for the first time."

One case more, from my own notebook. Patient 26 years old; previous history of syphilis; occupation, shoemaker. His work commenced as an apprentice in his fourteenth year; without intermission he had worked at his trade ever since, excepting for three years in which he per-

formed laboring work. The trade of shoemaking compelled him to hold a boot or board against his chest while working. He entered the hospital for acute rheumatism. Examination of the heart revealed no murmur, but a blowing systolic murmur could be loudly heard in the arteries of the neck, and down the aorta posteriorly. Anteriorly it is best localized at the junction of the left second costal cartilage with the sternum. The pulse in right radial artery much fuller than the left, and with a perfectly well marked trip-hammer or Corrigan pulse-quality. There was very slight dulness over the upper left border of the sternum; slight pain on pressure at this point. In this case, as in most others, these obscure phenomena were more thoroughly appreciated, and the diagnosis of aneurism made with greater certainty, by an analysis of the evidence in the following sequence. Let the mind be imbued by the belief that aneurismal tumors are always associated with or preceded by a diseased condition of the contiguous layers of the internal and middle coats of the vessel, a tissue-growth terminating in degeneration, which, by impairing the elasticity and contractility of the walls of the vessel, allows of their expansion and dilatation even under the tension of the normal arterial blood-pressure, or this abnormally increased by any cause, such as occupation, which acts as a fostering agent to the seeds already sown by the structural changes. In the second place, I believe that the structural change is in association in a major number of instances with syphilis, and in the order named with the other causes of endo-arteritis (atheroma),—viz., intemperance, Bright's diseases, and rheumatism.

In regard to the influence of syphilis, I have drawn my conclusions from observations in the Philadelphia and University Hospitals. In the former institution I have found a distinct or probable history of syphilis in fifty-five out of my sixty-nine cases. In the latter hospital all the cases to which I have had access in two years—some five or six in number—were associated with a syphilitic history. In a paper on aortic aneurism in the English army* the statement is made that, out of thirty-four cases occurring in the Royal Victoria Hospital, Netley, seventeen had a distinct and five a probable syphilitic history; three of associated syphilis or extreme indulgence in alcohol; two with well-marked rheumatic diathesis associated with acute manifestations; and only six without report as to systemic condition. The same writer states that, out of one hundred and seventeen cases, 46.1 per cent. of the cases gave undoubted syphilitic history, 6.8 per cent. more a probable history of syphilis; 21.3 per cent. occurred in phthisical subjects, 5.9 per cent. with heart-disease, 5.7 per cent. with various diseases, 14.2 per cent. without record as to constitutional state.

Ziemssen states that aneurism is eleven times more frequent in the English army than in civil life. The former writer believes army life the equivalent to a statement "laborious life," and that this acts as an exciting cause second to the predisposing causes cited: so that our first step, in my estimation, is one in the direction of etiology. (2) In the second place, study carefully the pressure-symptoms in view of the already-determined etiology: this will alone be usually sufficient to enable us to differentiate aneurismal pressure-symptoms from other tumors, even though murmur be absent. Mistakes in discrimination between the pressure-symptoms of morbid growths can thus be often avoided. For example, the causes of aneurism lead to its development in daily life. Chiefly it occurs between the ages of twenty-six and forty years, after which, if blood-vessel lesion occur, it will oftener be of the variety known as equable dilatation of the aortic coats,—since atheroma in these cases is not so apt to be inflammatory as due to a prior fatty degeneration of the aortic tissues. Time will fail me to allude in detail to these symptoms; but I am sure that pain of a persistent character, mitigated by changes of attitude, indicating that the pain is of mechanical origin, and that change of posture will remove the pressure from the tissues,—this sort of pain is a cardinal pressure-symptom, which must be early sought out and recognized. For example, in the cases cited, the pain as a pressure-symptom was manifest in all, more or less pronouncedly, and the associated symptoms, when correlated on this method, point distinctly in one direction, whereas they might otherwise be ignored, or not given sufficient importance to be of value. Careful percussion of the sternal region will often be helpful. Over this bone we normally find resonance, but by percussion, particu-

* Medico-Chirurgical Transactions for 1876.

larly if made during the forced expiration, when the lungs are separated from the contiguous aorta, slightly impaired resonance can be demonstrated over the aortic tract, if aortic enlargement exists. Questions as to the value of murmur are, I think, adjudicated by the axiom that murmurs are heard with maximum intensity at that portion of the circulatory tract where the cavities in which the murmurs are generated approach closest the chest-surface. Thus a murmur becomes strikingly indicative of aortic lesion when heard with maximum or equal loudness over that vessel. As the outcome of my special study, I believe that when a murmur is prolonged and systolic it indicates a simple dilatation of the aorta, or that the tumor connects with the aorta by a very small opening, as typified in the aneurism of the cœliac axis which I cited in the early part of this paper, or else that the tumor is filled with clots of fibrin. The latter point is confirmed if the murmur is more muffled than usually noted in aneurisms containing blood, which are relatively equally superficially or deeply situated.

There is one symptom to which I would like to direct your special attention, as I have occasionally observed it as indicative of aortic enlargement,—viz., the Corrigan pulse without aortic regurgitation. In an elaborate paper Dr. Galabin* has shown that this pulse may exist without aortic regurgitation, as an exaggeration of the normal pulse brought about by relaxed arterial tension; and he cites many sphygmographic tracings to illustrate his position. I have not noticed a typical Corrigan pulse, except in aortic regurgitation, or a state of aortic enlargement, probably dilatation. I say "probably," because the cases are still living. I can understand that in an enlarged atheromatous aorta the recoil of the blood after the cardiac systole may be as marked as in cases of aortic regurgitation; for the blood is almost always powerfully propelled by an hypertrophied ventricle (though cardiac hypertrophy is not necessary to develop this pulse); but, as the vessel is above normal size, the volume of blood is not sufficient to distend the vessel and develop a gradual arterial systole to propel it forward, but the aortic recoil is abrupt, and the jerking pulse is the consequence. If the crasis of the blood is impaired, as in anæmia, there may be an intensified Corrigan pulse; but I have not noted the peculiar characteristics of the Corrigan pulse in simple anæmia, or in cases of relaxed arterial tension.

Finally, then, in regard to the special symptomatology of aortic aneurism, each case is a special study, and I am well aware that the palm of successful diagnosis will most frequently reward the observer who includes the sum of the evidence of the symptomatology in his judgment. But, by the method of study I suggest, the associated symptoms of aneurism are brought into relief, and under-estimation avoided. The importance of accurate diagnosis cannot be over-estimated. "To know our enemy is, if not 'half the battle,' at least a most important part of it."

In dealing with disease, accuracy in diagnosis is only second in importance to therapeutics, the science of therapeutics being based upon the tripod of physiological experimentation, clinical observation, and comparison, combined with pathological research.

ETHYLENE BICHLORIDE AS AN ANÆSTHETIC AGENT; WITH A CONSIDERATION OF ETHYLENE METHYLETHYLATE, ETHYLENE ETHYLATE, ETHYL NITRATE, AND ETHYLIDENE BICHLORIDE.

BY EDWARD T. REICHERT, M.D.

(Continued from page 492.)

THE Pulse.—The pulse-rate is invariably and decidedly increased, even in the most profound narcosis, and not until near death does it approach or fall below the normal, as the following records will show, which have been copied from kymographion tracings:

Exp. I. (*October* 5, 1880).—*Rabbit.*

Time. M. Sec.	Pulse in ten sec.	Remarks.
1.	37	
.05		Commenced inhalation by Woulfe bottle. The animal was previously curarized, and artificial respiration was resorted to, the apparatus being connected with the Woulfe bottle.
.15	37	
.55	38	
2.35	46	
3.15	48	
.55	45	

Time. M. Sec.	Pulse in ten sec.	Remarks.
4.35	48	Anæsthetization complete. Maximum increase 11, or 29 per cent.

Exp. II. (*October* 6, 1880).—*Rabbit.*

Time. M. Sec.	Pulse in ten sec.	Remarks.
1.	45	
		Commenced inhalation as previously on an animal similarly rendered immovable.
.25	46	
.45	45	
2.05	47	
.25	48	
.45	58	
3.05	53	Animal anæsthetized.
.25	55	
.45	61	
4.05	54	
.25	47	
.45	54	
5.05	52	Maximum rise 16, or 35 per cent.

Exp. III. (*October* 7, 1880).—*Rabbit.*

Time. M. Sec.	Pulse in ten sec.	Remarks.
1.	33	
.05		Commenced inhalation with the use of the cone of muslin, it being held over the tracheal tube.
.20	37	
2.	38	
.40	45	
3.20	42	
4.		Added more ethylene to inhaler.
.40	48	
5.20	48	
6.	47	Respirations ceased.
.40	47	
7.20	45	
8.	47	Respirations commenced, but are shallow.
.40	44	
9.	46	Respirations became slower and deeper, and finally ceased. The heart continued beating for at least four minutes, and gradually ceased. Maximum increase 15, or 45 per cent.

Exp. IV. (*October* 9, 1880).—*Rabbit.*

Time. M. Sec.	Pulse in ten sec.	Remarks.
1.	36	
.03		Commenced inhalation by the use of the linen cone.
.07		
.32	39	
.42	39	Arterial pressure falling slightly.
2.07	49	Arterial pressure rising slightly.
.27	46	The arterial pressure slowly rising; the pulse-curves are about one-third the height of the normal; the respirations are scarcely perceptible.
.47	46	Arterial pressure a little lowered, and equalling about seven-eighths of the normal.
3.07	48	
.27	46	Arterial pressure rising slightly.
.47	46	
4.07	48	Arterial pressure falling, and equalling about three-fourths of the normal.
.27	45	
.47	50	Arterial pressure falling slightly.
5.07	54	
.47	45	
6.07	46	
.27	48	Arterial pressure falling slightly.
.47	44	Arterial pressure falling, and equalling about five-sevenths of the normal.
7.		Added more ethylene to inhaler.
.07	46	
10.	45	
.20	46	
.40	46	
11.	46	
.20	45	
.55	46	
.58		Added more ethylene to inhaler.
12.15	46	
.35	46	
.55	46	
13.15	46	
.40	45	
15.	46	
17.	43	
20.	43	
.20	43	
.30		Added more ethylene to inhaler.
.40	45	
21.	50	
.20	48	
22.15	45	
.35	42	
.55	47	
23.15	45	
.35	43	Arterial pressure one-half of the normal.
24.15	43	
25.35	40	
26.05	42	
.25	47	
.45	42	
27.05	43	

Time. M. Sec.	Pulse in ten sec.	Remarks.
.25	42	Arterial pressure three-eighths of the normal. Maximum increase 18, or 50 per cent.

At the time of the conclusion of this record the pulse-curves had become so small as to be indistinguishable, and the tracing made by the marker was but a mere streak. When the fingers were placed on the chest of the animal, only a faint movement of the heart was perceptible, and the action of the viscus was more like tremors than distinct pulsations. The respirations at this time, if they were present at all, were so shallow that they were indiscernible.

The animal was allowed to remain undisturbed for about two minutes, and when a further examination was made the movements of the heart were found to be so feeble as to be almost inappreciable, and not the slightest respiratory movements were detected. The heart still possessing some vitality, it was thought that by attaching the artificial respiration-apparatus to the tracheal tube the respirations might possibly be restored and the moribund animal revivified. This was done, and after the lapse of two minutes not the least evidences of respiratory movements or of a restoration of the vitality of the almost paralyzed heart were present, and, as all signs of life save the almost imperceptible movements of the heart were gone, the animal was given up as being of no further use, and the artificial respiration-apparatus detached. In a few moments, however, it occurred to the writer that as this drug was probably both a cardiac and a respiratory depressant in toxic amounts, and that, as previously stated, death invariably occurred from a paralysis of the respiratory movements, we would have an invaluable antidote and revivifier in the nitrites if what the writer asserted in a recent article* was true, which was to the effect that the nitrites, in small or moderate doses, were powerful respiratory and cardiac stimulants, and, although the long-continued absence of respiratory movements and the almost complete extinction of all the vital functions were points decidedly against a successful result of such an experiment, yet, while a negative result would not therefore materially disprove the above assertion, the opposite result would be strong, if not almost conclusive, testimony in its favor. The amyl nitrite was quickly obtained, and in a few moments as many drops (probably five) were quickly injected into the tracheal tube, and the artificial respiration-apparatus again attached, so that the vapor of the nitrite would be forced into the lungs and thus become absorbed. In a few moments, to my intense gratification, the almost paralyzed heart seemed invested with a new life, and every moment its lost powers were being rapidly restored, the pulse-curves gradually increasing in height and volume, and in a less time than it takes to pen these notes were equal to the normal, and the heart was pulsating at the rate of forty beats in ten seconds, or four pulsations above the normal. The respirations did not recur for at least two minutes, and were then both shallow and slow, but in a few moments they had become so rapidly restored that they occurred at the rate of thirty-six per minute; two minutes later they were twenty-two per minute; at the seventh minute they were again thirty-six and the pulse in ten seconds forty-two; at the eleventh minute they were forty-two; at the fifteenth minute they were fifty-one and the pulse in ten seconds forty-two. Several drops of the nitrite were twice injected into the tracheal tube since the first recurrence of respiratory movements.

At the commencement of the inhalation of the amyl nitrite the arterial pressure was about one-third of the normal, and at the end of fifteen minutes it had not materially changed either one way or the other, although slightly lowered, which was quite contrary to what might be expected, since there was an augmentation of the frequency as well as of the force of the heart; but when it is remembered that the nitrites cause such intense vaso-motor dilatation, and that, notwithstanding the fact of their being decided cardiac stimulants, they cause a decided lowering of the blood-pressure in normal animals, the explanation of this apparent anomaly is evident. That we have in the nitrites an invaluable class of physiological antidotes for this compound is so clearly proven by the above as to need no further comment.

To return to the results of the preceding

* American Journal of the Medical Sciences, July, 1880, p. 158.

four experiments made on normal animals. It will be noticed that a decided increase in the pulse-rate invariably occurs, and that this increase continues far above the normal until immediately before death (Exp. III.), when it gradually failed, the increase being, respectively, 29, 35, 45, and 50 per cent., and the average about 40 per cent. The pulse-curves were diminished (Exp. IV.), and the arterial pressure decidedly lowered. In order to determine the *modus operandi* of this increased pulse-rate, it was first sought to decide whether the vagi apparatus was concerned: so the following experiment was made, in which both vagi nerves were severed, a tracheal tube was inserted, and the ethylene given by inhalation from a muslin cone, with the following result:

Exp. V. (*October* 13, 1880).—*Rabbit.*

Time. M. Sec.	Pulse in ten sec.	Remarks.
		Cut the pneumogastric nerves.
1.	35	
.03		Commenced inhalation.
.10	35	Arterial pressure reduced about one-tenth of the normal.
.30	34	
.50	34	
2.10	37	Pressure rose since 1.50, and is now about one-tenth of the normal above it. The respirations had now become very frequent, and for one minute the pulse-curves were not traced, only the respiratory curves. The respirations, which were normally seven in twenty seconds, are now increased to thirty-seven. The arterial pressure falls gradually until 3.15, when it reaches one-tenth below the normal; it then arose slightly, followed by a fall to the former point.
3.20	42	Pressure one-tenth below the normal, and gradually declining.
.40	42	
4.	42	
.35	42	
.55	42	
5.15	50	
.35	52	
.55	53	
6.30	46	Pressure one-fourth below the normal.
.50	45	
7.10	45	
.30	44	
.50	45	
8.25	46	
.45	45	
9.05	46	Pressure about five-twelfths below the normal.
.25	46	
.45	47	
13.	45	
.20	46	
.30		Added more ethylene to inhaler.
.40	44	
14.	45	
.20	43	
.32		Respirations ceased.
.40	38	
15.	29	
.35	26	
16.15	27	
.55	28	
17.25	26	
.45	27	Since the fifteenth minute the pressure has gradually declined, and is now about one-fourth of the normal.
.55		The cardiac pulsations are so feeble as to be imperceptible, and at 18.25 the pressure fell to zero. Maximum rise 18, or 51 per cent.

It will be noticed that the result in this last experiment is identical with those made on normal animals, with the exception that a rise of the arterial pressure occurred which went above the normal. The pulse-rate was increased 51 per cent., which was as much as the greatest increase in any of the preceding observations, and, although the pulse-curves were not referred to in the preceding remarks, yet the same diminution of their size was apparent. It is therefore evident that the increased pulse-rate occurs independently of the pneumogastric nerves, and that it must be due either to a direct cardiac action or to a stimulation of the accelerator nerves. The determination of this point is satisfactorily accomplished by making, in the same animal, a combined section of both the cervical spinal cord and vagi nerves (in the section of the former the accelerator nerves are severed before their exit from the cord). This operation has been done in the two following experiments:

Exp. VI. (*October* 12, 1880).—*Rabbit.*

Time. M. Sec.	Pulse in ten sec.	Remarks.
1.	41	
.10		Commenced inhalation by Woulfe bottle.
.30	38	
.50	38	
2.40	35	

Time. M. Sec.	Pulse in ten sec.	Remarks.
3.	34	
.20	36	
.40	40	
4.05	40	
5.	37	
7.	24	
9.	21	The pulse continues failing.

Exp. VII. (*October* 14, 1880).—*Rabbit.*

Time. M. Sec.	Pulse in ten sec.	Remarks.
1.	39	
.10		Commenced inhalation by Woulfe bottle.
.20	32	
.40	30	Pressure has fallen one-half of the normal, and is still declining.
2.15	35	
.35	27	
.55	20	
3.15	20	
.40	34	
4.	34	
.20	34	Pressure about one-third of the normal.

These results being directly the reverse of what has hitherto been recorded, it is very evident that the increased pulse-rate such as occurs in normal animals is dependent upon a stimulation of the accelerator nerves. Were it dependent upon the heart, the increase would still be apparent in animals operated on like the above, but which is not the result here; and it is an interesting fact to note that instead of the increase we have a diminution below the normal from the first; and the fact that the heart is isolated from the reception of any centric influences shows that the decline of the pulse is due to a depression of the heart itself. The consentaneous occurrence of a diminished pulse-rate, diminished pulse-curves, and diminution of arterial pressure decidedly indicates cardiac depression, and is undoubtedly due to this, unless it be the diminution of arterial pressure, which may possibly, to a considerable extent, be due to vaso-motor dilatation.

A decided increase of the pulse-rate occurring in normal animals or in those having the accelerator nerves intact, and a diminution occurring in those in which the nervous connections of the heart were severed, is an exceedingly interesting point, and shows that the heart in normal animals is affected consentaneously in a dual manner, and that these two forces are in constant antagonism, the one tending to cause an increase through a stimulation of the accelerator nerves, and the other a diminution by a direct paralyzant action on the heart. And it is evident that the effects of the stimulation of the accelerator nerves are more intense than those of the direct action on the heart: hence we have the increase. In two dogs, one in which the fibres of the accelerator nerves were cut a little below the medulla oblongata, and to which intravenous injections were given, the results, as the following records show, are confirmatory of what has already been stated.

Exp. VIII.—Dog.

Time. M. Sec.	Pulse in ten sec.	Remarks.
1.	16	
.10		Injected thirty minims intravenously.
.22		The blood-pressure fell rapidly to one-half of the normal; deep respirations and struggles sent it up to normal twelve seconds later; it then commenced to decline, reaching one-half of the normal at thirteen seconds later; and then commenced to rise gradually, reaching to within one-eighth of the normal at the fourth minute.

(To be continued.)

EXPERT MEDICAL TESTIMONY.

BY C. H. BOARDMAN, M.D.

TO the evils inseparably associated with the existing system of procuring so-called expert evidence which are set forth in Dr. Reese's thoughtful paper in a recent number of the *Medical Times* might be added one which, while less calculated than its congeners to bring the science of medicine into disrepute, is potent in defeating the very *raison d'être* of such evidence.

The physician whose services are desired is sought by the counsel for either of the parties to the suit, who lays before him a purely *ex parte* statement and requests thereupon an expression of his opinion. The narrative is plausible, and, whether inadvertently or otherwise, there is usually no reference to modifying or ameliorating circumstances, a knowledge of which might have no little weight in determining the witness (*in posse*) as to the proper course to be pursued. He is naturally impressed by the story thus forcibly presented, and, unaccustomed to weighing evidence,—unable, indeed, to weigh it, since he holds but one-half of the scales,—he becomes a victim to that scourge of the human race, hasty generalization, and straightway appears in court, not as an unbiassed witness whose function it should be to decide scientific questions beyond the ken of the jury, but as an advocate, pure and simple, who desires chiefly that the cause for which he appears shall triumph, and who, becoming heated as the fires of cross-examination grow hotter, is very apt insensibly to color his evidence that it may correspond with the mental verdict at which he has long since arrived.

The inevitable result of a system which brings forth such fruits is seen in the present status of expert evidence in our courts, where it is no uncommon thing for juries to throw out the whole in finding their verdict, paying no more attention to it than though it had never been. That this should be the case is a blot upon the fair fame of our profession, and it is felt as a reproach and a disgrace, especially by those physicians who are practically conversant with forensic medicine, and who are rightly jealous for the good name and reputation of their chosen calling.

The existence of grave abuses in our system of medical jurisprudence is very generally recognized by physicians; it furnishes a text for numerous threnodies in the Transactions of our various State medical societies; but as yet no determined or systematic effort has been made to remedy the evil. If the proper remedy can be devised, then, doubtless, energetic concert of action will result in its adoption, and we shall rid ourselves of the opprobrium which, in this respect, now rests upon us.

It has long seemed to the writer that the ideal system is that to which reference is made by Dr. Reese,—viz., the Imperial Commission of Prussia, of which Casper was so long the honored chief; but, at the same time, it is perhaps a question whether such an organization is practicable in this country, and the plan proposed by Dr. Reese is more in harmony with the genius of our institutions. It may be, however, that a measure which the Legislature of Minnesota was solicited to adopt at its recent session would be still more acceptable, and, if not productive of as good results, it might provoke less opposition and prepare the way for subsequent improvements.

The proposition as urged upon the Judiciary Committee of the House was as follows: Counsel for both parties shall prepare lists of physicians whom they are willing shall be called as witnesses, and from these lists the court shall select a certain number (say three or five), who, subpœnaed by the State, shall, after hearing all the evidence, express their opinion, having a previous consultation, if so desired. The defendant, of course, retains the right to summon his own experts, if he wishes to do so.

It is not claimed that this scheme is the best that can be devised, or that it is free from objections, but it is a vast improvement upon the method now in vogue, and, as said before, it is believed that the attempt to secure its adoption would arouse but little opposition, while a determined hostility would probably be arrayed against a more radical measure of reform. It does not provide, as does Dr. Reese's plan, for a State toxicologist, but, if it be thought best, such an official might be appointed, thus combining Dr. Reese's scheme with that proposed in this communication.

If our various State and County organizations will but agree upon some practicable substitute for the absurd and anom-

alous proceedings now relied upon in our courts, it cannot be doubted that an intelligent and combined effort will secure its adoption, since a reform so greatly needed would be welcomed alike by the members of the professions of law and medicine.

ST. PAUL, MINNESOTA.

OVERDOSING AND GIVING DISAGREEABLE MEDICINES UNNECESSARILY.

BY WALTER C. STILLWELL, PH.G., M.D.

A SHORT time since, in conversation with a druggist who compounds prescriptions from a great number of different physicians, he spoke of the large doses which some of them gave, and, to illustrate, he got down his prescription-file for that day and showed me a recipe for powders of cubebs, alum, and cinnamon so large that one of them filled twice a tablespoon heaping full, and when mixed in a half-glass (four ounces) of water it made a dose that almost any human being would rebel against. Now, as two or three drops of the oil of cubebs and one-tenth of a drop of that of cinnamon would represent the amount of the respective remedies, a pleasant instead of an offensive compound could readily have been made.

Here is the latest treatment for tapeworm, reported in a recent number of a medical journal,* and noticed in the *Times* (No. 341), and, as it has a bearing upon the subject, I repeat the main features of the treatment: "The patient takes a dose of castor oil, then milk diet for twenty-four hours, and no other food except a salad of salt herring, onions, and garlic; then he takes a mixture of a decoction of pomegranate-root, ethereal extract of male fern, sulphuric ether, fluid extract of valerian, croton oil, and honey." At this period of the treatment the patient can take more herrings and onions, if he wants them. "As soon as the mixture produces colic, an ounce of castor oil is administered hourly until the worm is expelled."

If the patient lives through all this, and the worm succeeds in clinging to the mucous coat of the intestines after passing through such an ordeal, it deserves to remain there unmolested the remainder of its existence. It is such barbarous treatment as the foregoing which sends patients to homœopaths.

A prescription was presented at a drug-store to be compounded, not long ago, containing a number of ingredients, among them a preparation of iron and also a vegetable astringent. It was compounded and delivered to the patient; he immediately returned it to the store, with the remark that "he did not want ink." The druggist referred him to the physician who prescribed it; he told the patient that "if he prescribed ink it was his place to take ink;" and he did, and when he had any writing to do he would use his medicine as a writing-fluid, and when his inkstand wanted replenishing he would always get his prescription renewed.

I am satisfied that the followers of Hahnemann get many patients which they would not otherwise by the regular practitioners dosing children with disgusting medicines, for how often do you hear mothers say that they consider homœopathic medicine is "good for children"! I do not wish to be understood as advocating trifling with disease by using mild means merely to please the patient and gain credit for giving agreeable medicines, for I believe in administering any drug, no matter what is its character, when there is urgent necessity for it.

I think this subject is not sufficiently appreciated by physicians generally, as there is certainly room for great improvement in the preparation and the proper combining of remedies, so as to suit the patient's palate as well as his system.

I am accustomed to have made up at a drug-store a recipe which could be called either a syrup or an elixir; I give it for what it is worth. A half-fluidounce of the compound added to a four-ounce mixture containing disagreeable-tasting medicines, such as bromide and iodide of potassium, bichlorate of sodium or potassium, quiniæ sulph., and many others, will cover a multitude of imperfections in a prescription as regards color, taste, etc.

This is the formula:

℞ Aurantium cortex recens, i;
Sem. anisi (cont.), ℥ij;
Sem. cardam. (cont.), ℥i;
Sem. fœniculi " ℥ij;
Coccus cacti " ℥i;
Sacch. albæ, ℥xxxij;
Sp. vini rect., f℥iv;
Aquæ, Ojss.

* New York Medical Record, November 20, 1880.

Macerate all of the ingredients except the sugar in the alcohol and water for four days, filter, and dissolve the sugar by the aid of gentle heat, and strain it while warm.

TRANSLATIONS.

EXPERIMENTAL RESEARCHES IN THE ABSORPTION AND ACTION OF METALLIC MERCURY.—Dr. Paul Fürbringer (*Virchow's Archiv*, Bd. lxxxii. p. 490) says that two questions remain to be solved with reference to this subject. 1. Does the metallic mercury of gray ointment penetrate as such into the system in ordinary inunction? 2. Is the metal oxidized by contact with the juices of the system?—that is, is it changed into an active soluble form? Dr. Fürbringer says that the first of these questions has been answered first affirmatively, then negatively, by successive investigators; the second question has only been investigated in the reagent-glass, and the result transferred to the account of the organism.

In investigating the subject, Dr. Fürbringer divides the first question into three parts, depending upon the method of absorption: (*a*) in the place of application, by mechanical passage of the globules through the skin; (*b*) by breathing the vapor; (*c*) by the penetration of the vapor through the skin.

After giving a thorough examination of the rather contradictory results obtained by previous observers, Dr. Fürbringer details his own careful experiments under these heads, with the conclusions which he has reached, and which are as follows: 1. By inunction with fresh gray ointment (free from oxidized mercury) into the intact skin and mucous membrane the metallic globules are forced into the hair-follicles and sebaceous follicles in the place of application, and, under the influence of the glandular secretion, are changed into a soluble absorbable combination. 2. The mercurial vapor taken in by respiration condenses in a metallic form on the accessible portions of the mucous membranes, and, remaining there, is gradually changed into an absorbable, soluble oxidized compound. On the other hand, neither do the metallic constituents of gray ointment penetrate through the uninjured skin at the point of inunction, nor does the metallic vapor penetrate through mucous membrane or skin to exist as such in the blood. In abraded skin, however, opportunity is given for the passage of metallic mercury into the circulation at the point of inunction by the existence of bleeding points in the skin. So soon as metallic quicksilver comes into contact with the living blood it is changed into a soluble active compound. Apart from this mechanical penetration of metallic quicksilver, the drug can only get into the system as above mentioned by becoming changed into some soluble salt when in contact with some denuded spot. [Fürbringer's results, though in contradiction to those of several investigators of distinction, appear to be founded on such complete and careful experiments as to make it likely that they will influence the present views on the subject of the absorption of metallic mercury.—ED.]

NERVE-STRETCHING—At a recent meeting of the Societé de Biologie (*Le Progrès Méd.*, 1881, p. 217), M. Quinquaud mentioned a case where he had stretched the frontal nerve for supra-orbital neuralgia. A little later one of his colleagues had performed the same operation for epileptiform neuralgia of the face, and also for a supra-orbital neuralgia. The first and third of these operations had been successful, the second less so. But in the two successful cases complete anæsthesia had supervened, which continued up to the present time. On the other hand, in the case of epileptiform neuralgia the anæsthesia following the operation only lasted a few hours. It follows from this that in such operations anæsthesia must follow if the cure is to be permanent. The explanation of the cure in these cases of nerve-stretching has been in dynamic action; but practical knowledge has hitherto been wanting. M. Quinquaud now supplies this lack by experiments upon animals. He has ascertained that when the nerve is stretched, if the cure is to be permanent, persistent anæsthesia must be produced. On the other hand, in cases where anæsthesia has been produced, secondary degeneration can be observed in a considerable number of nerve-tubules. Some show their myeline granular and segmented, others are completely emptied, others are intact. M. Quinquaud concludes that what is required is complete anæsthesia, not by dynamic action, but by anatomical change. In the discussion which followed, M. Dumontpallier remarked that in the case re-

ported by M. Debove and himself, neuralgia was relieved by nerve-stretching, but anæsthesia did not follow. M. Quinquaud replied that in the case of this same patient a recent examination by M. Laborde had shown complete anæsthesia.

Later in the course of the meeting, M. Laborde presented, for M. Marcus, the results of some experiments of the latter on nerve-stretching in the guinea-pig. On the third day after operation, examination showed some nerve-fibres intact, while others were altered with segmentation of the myeline. In the cat the same results were obtained, but more slowly. A curious fact was that the degeneration took place only in the central portion of the nerve: the peripheral portion remained intact. Without taking this result for granted, M. Laborde thought that the effect of the compression sustained by the nerve at the point of traction could be seen in this last result.

Visceral Atrophies consecutive to Inflammation of Serous Membranes.—From a review of a work on this subject by Dr. A. Poulin, in *La France Médicale* (1881, p. 382), we learn that atrophy of the lung may be produced as a result of inflammation of the serous membranes by two somewhat different processes. In most cases the parenchyma of the viscus is compressed by abundant serous effusion. This not being absorbed, a thick neo-membrane covers the visceral pleura and the compressed lung in a sort of husk, preventing its expansion entirely. When finally the serous effusion has disappeared, the lung is incapable of dilating, its atrophy is complete, and the void left between it and the thoracic wall is closed by the contraction of the latter. In rarer cases, when the pleurisy is dry, the two reflections of the pleura become adherent, prevent expansion on the part of the thoracic walls, and thus draw in the thorax, compressing the lungs at the same time. In addition, a "pleurogenetic pneumonia" may be brought about when fibrous bands form in the lung itself.

As regards the liver, atrophy by perihepatitis is rarer, and is sometimes difficult to distinguish from atrophy the result of cirrhosis, which is frequently accompanied by thickening of the serous envelope. In certain cases of chronic peritonitis the thick neo-membranes formed develop over the surface of the liver and mask it entirely. The diminution in the volume of the organ which almost always exists in these cases is due to a complex morbid process: direct compression of the hepatic gland, according to Cruveilhier; propagation of chronic inflammation to the interstitial tissue of the liver, according to Thierfelder; obstruction of the circulation in the narrowed hepatic vessels, according to Murchison and Hilton Fagge. Poulin gives the first place among these causes to compression of the vessels. Superficial cirrhosis by propagation, though it has been demonstrated to exist by numerous observations, appears to exercise a minimal influence.

Plastic Operations on Muscles and Tendons.—Gluck (*Cbl. f. Chir.*, 1881, p. 168; from *Archiv f. Klin. Chir.*), who has succeeded so well in transplanting bits of nerve, has recently transplanted bits of muscle, with and without tendon, also successfully. In a series of researches upon chickens, a bit of muscle the size of a dollar was extracted, and its place filled with muscle from a rabbit, which invariably grew in without difficulty and often showed the muscular structure without change. In a second series of researches in chickens, a bit of the gastrocnemius was cut out, with some tendon attached, and replaced by a somewhat larger piece from the corresponding part of another chicken. This piece, together with its tendon, grew in successfully. Forty days after the operation the new muscle showed its specific action. An energetic process of regeneration only showed itself when the inflammatory reaction was as far as possible eliminated. Where there is decided inflammation, the transplanted portion is more or less changed into a fibrous mass; that is to say, the whole muscle is changed into a semi-membranosus by the plastic operation. This would have to be taken into account in any operation performed upon man.

A Patient's Agreement to Pay Repudiated by Law.—A paralytic Parisian, having injured his ankle, called in Dr. Alphonse Guérin, the well-known surgeon, who attended him, dressing the limb thirty-one times. For this service he sent in to the heirs of the patient (who died shortly after) a bill for 6900 francs,—$40 per visit. The heirs thought $20 per visit enough, and went to law, when the court decided that no agreement could be made between a patient struggling for life and the person he calls in to save him.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, MAY 21, 1881.

PROCEEDINGS OF SOCIETIES.

THE AMERICAN MEDICAL ASSOCIATION.

THE thirty-second annual meeting of the National Association was held in Richmond, Virginia, commencing Tuesday, May 3, and continuing until Friday, May 6, 1881. Nearly five hundred delegates and members were in attendance.

According to the programme, the meeting was convened at eleven o'clock A.M., with prayer by Bishop J. J. Keane, after which Hon. F. W. M. Holliday, Governor of the State, delivered an eloquent address of welcome.

The Committee of Arrangements announced the order of business, as well as the entertainment and invitations from several sources.

The President of the Association, Dr. John T. Hodgen, of St. Louis, then delivered his annual address, in which he referred to the two types of surgeon,—the bold, reckless operator, and the conservative, timid one,—and warned his colleagues against the temptation to perform brilliant operations when the patient's best interests would be furthered by a more tentative course. On the other hand, he urged early interference in proper cases, such as malignant disease, sarcoma of choroid, rodent ulcer, and sympathetic ophthalmia. Various conditions of the body tend to render an operation unsuccessful: previous vigorous health in itself will prevent a patient from patiently bearing confinement; a strumous constitution, long-continued mental strain, anæmia, and wasting disorders, all tend to reduce the powers of recovery. Imperfect knowledge of many pathological states also would prevent the resort to the knife, in the absence of exact information of the state of the system. After referring to the many advances in operative surgery, he concluded by saying that a more perfect animal chemistry, a more thorough histology, and a deeper search into the possibilities of pathological change will doubtless throw many a ray of light into regions where the darkness is now too dense for our vision to penetrate. To these fields coming generations of physicians will surely be attracted, in the faith that, as man advances in knowledge and approaches somewhat nearer to the comprehension of the perfect wisdom which designed the wonderful physical organism through which he is brought into relation with the world around him, he will be enabled to solve more and more of the difficult problems which now perplex and baffle us, and will gradually raise medicine to a position more nearly akin to that now accorded to the exacter sciences.

The address was attentively listened to and warmly applauded. A vote of thanks was passed to Dr. Hodgen, and the paper referred to the Publication Committee.

Dr. Jos. H. Warren, of Boston, chairman of Foreign Delegates appointed at the last meeting, reported attendance upon the British Medical Association at Cambridge, and gave an interesting report of the proceedings at that meeting. In conclusion, he spoke of the *British Medical Journal*, and advocated the establishment of a similar official periodical by the Association.

PROCEEDINGS IN THE SECTIONS.

SECTION I.—*On the Practice of Medicine, Materia Medica, and Physiology.* Dr. Wm. Pepper, Philadelphia, Chairman; Dr. T. A. Ashby, Baltimore, Secretary.

In the absence of the chairman, Dr. Octerlony, of Louisville, occupied the chair.

Dr. W. C. Wile, of Connecticut, read a paper on "Blood-Letting as a Therapeutic Measure in Pneumonia," in which he advocated the free use of the lancet in the early stage, and reported several cases apparently greatly relieved by the venesection.

Dr. J. J. Lynch, of Baltimore, protested against this method of treatment, as the disease runs its course in spite of the bleeding, and the patients recover just as soon without it. When bleeding was common, the mortality of pneumonia was about twenty-five per cent.; now it is scarcely more than four or five per cent. Dr. Whitaker, of Cincinnati, also entered a vigorous protest against this procedure, which he considered as being unjustifiable. Veratrum viride, also recommended by the lecturer, is a profound cardiac sedative, and might do much harm.

Dr. N. S. Davis advocated the treatment, and Dr. S. D. Gross said that it was applicable to the first stage in young, robust subjects, where he considered it to be the great remedy. The subject was still further discussed until the time of adjournment.

SECTION II.—*On Surgery and Anatomy.* Dr. Hunter McGuire, Virginia, Chairman; Dr. Duncan Eve, Tennessee, Secretary.

Dr. Jos. H. Warren, of Boston, exhibited a number of instruments, among which were catheters and bougies with a screw or vermicular point; a modification of Thomson's evacuating tube for the bladder after crushing a stone, or for removing foreign bodies; a uterine probe with a rotary point, a trocar, and a set of sounds for the urethra or uterus on the same principle. Also a serrated herniotome, torsion forceps, a hernia syringe, and a peculiar dissecting-knife.

Drs. Sayre and Gouley, of New York, could

not discover anything in the revolving point to commend its use.

Dr. Wm. A. Byrd, of Quincy, Ill., reported a case of ulceration of the appendix vermiformis, with remarks upon abdominal section in cases of perforation of the bowel. In the discussion, operative interference was strongly recommended.

Dr. James E. Reeves, of West Virginia, exhibited a renal calculus, weighing 480 grains, from a case of pyonephrosis. A number of smaller calculi coexisted, weighing in the aggregate 416 grains.

SECTION III.—*Obstetrics and Diseases of Women.* Dr. James R. Chadwick, Boston, Chairman; Dr. Joseph Tabor Johnson, Washington, Secretary.

Dr. Paul F. Mundé opened the discussion upon vaginal and vagino-abdominal pessaries, and formulated a number of propositions as guides to their use, as follows:

1. Always be sure of the diagnosis, of the nature and degree of the displacement, before resorting to a pessary.

2. Always replace the uterus before applying a pessary, especially in retro-displacements. Preliminary treatment by frequent replacement and straightening the canal with a sound will often be beneficial.

3. Never insert a pessary when there is evidence, by the touch, of acute or recent inflammation of the uterus or adnexa, or when pressure by the finger on the parametrium (where the pessary is to rest) gives decided pain.

4. When the uterus is not replaceable,—that is, when adhesions bind the fundus down,—use great caution and discrimination in deciding whether an attempt should be made and is justified by the symptoms to elevate the fundus by manual or instrumental means, or whether the elevation should first be tried by the gradual elevation of a pessary (this applies only to retro- and latero-versions). If neither is to be recommended, do not introduce a pessary until local alterative and absorbent measures have effected a resolution of the adhesions.

5. Always choose an indestructible instrument, if possible. This does not apply to prolapsus uteri.

6. Always measure and estimate the vagina carefully before choosing a pessary, and be careful to adjust the pessary in every particular (size, curve, width) to that particular case. No two vaginæ are exactly alike.

7. If the vaginal pouch is not sufficiently deep to accommodate a pessary (anterior pouch for ante-displacements; posterior pouch for retro-displacements), defer the attempt to fit a pessary until the pouch has been deepened by daily tamponing with cotton, or by the upward pressure of a Cutter or a Thomas vagino-abdominal supporter. Or the pouch may be gradually deepened by using first a small (slightly curved in retro-displacement) instrument, and gradually increasing its size (or curve) until the desired size and shape for permanency are reached.

8. Never leave a pessary in the vagina which puts the vaginal walls to the stretch, and which does not permit the passage of a finger between it and the wall of the vagina. This does not apply to prolapsus uteri.

9. A vaginal pessary which projects from the vulva is displaced.

10. A pessary which gives pain must at once be replaced by one which is painless.

11. A well-fitting, properly-chosen pessary should not only give no pain, but should be a direct source of comfort to the patient.

12. Always examine a patient on her feet after introducing a pessary, or when it is desired, at her return, to ascertain its efficiency in sustaining the uterus during walking and exertion.

13. Always tell the patient that she has a pessary in her vagina, or she may not return in spite of your directions, and the pessary may remain for years, to her ultimate great discomfort and danger.

14. Always tell the patient to return within a week after the first introduction, in order that the position and working of the pessary may be looked after, and that, if it does not suit, it can be removed and a better one inserted. Tell her that several trials and various instruments may be required before one is found which she can wear permanently. Also let her return for inspection once every four to eight weeks, as the case may require. Tell her that if she fails to do so the pessary may cause ulceration, for which treatment will be needed.

15. Tell the patient that she will need to wear the pessary for months, perhaps years, before a recovery can be expected.

16. Never introduce a pessary which the patient cannot remove herself.

17. Tell the patient to remove the pessary herself if it gives pain, and show her how to do it. When she has removed it, let her present herself at once for examination.

18. Tell the patient to use daily vaginal injections for cleansing purposes. If she notices profuse discharge, add astringents; if the discharge is sanious or purulent, let her come at once, as the pessary has probably caused abrasion.

19. Tell her on moving the pessary to test the result; that the permanence of the result cannot be determined for several days or weeks.

20. Always direct your patients to relieve all superincumbent pressure by a proper support of their skirts. If the displacement be anterior, aid the pessary by an abdominal supra-pubic pad.

All pessaries may be introduced in the knee-chest position when it is desirable or possible to replace the uterus only in that position. A Sims speculum elevates the peri-

neum, the air enters and expands the vagina, and the pessary (chiefly in retroversion and prolapsus) is introduced by touch and sight, and the patient laid over on her left side. For aggravated retroversion and for prolapsus of ovaries or uterus, this position offers many advantages over the left semi-prone decubitus. Care must be taken to remember that the position of the patient is reversed, and that the pessary must be introduced accordingly.

Dr. R. Beverly Cole spoke in favor of the Hodge pessary and his own modification of it with a spring support for retroversion. He also advocated the use of the galvanic stem pessary in the condition of atony. In conclusion, he exhibited a gas cautery for operations upon fungous growths, etc., and demonstrated the method of moulding gutta-percha, previously softened in warm water, so as to make extemporaneous pessaries.

Dr. Albert H. Smith deprecated the indiscriminate use of pessaries; he did not believe in the galvanic action of the stem pessary mentioned, but considered its effects merely mechanical.

A number of other speakers united in discouraging the use of stem pessaries.

SECTION V.—*On Ophthalmology, Otology, and Laryngology.* Dr. Dudley S. Reynolds, Kentucky, Chairman; Dr. S. M. Burnett, District of Columbia, Secretary.

Dr. W. C. Jarvis, of New York, read a paper on "Nasal Catarrh with Hypertrophy," and advocated transfixion of the hypertrophied portion by curved needles, and its removal by a wire écraseur in preference to the galvano-cautery or the knife. The paper was followed by a general discussion on nasal catarrh and its causes.

Dr. Chisolm, of Baltimore, read a paper on "Conical Cornea," in which a case was reported benefited by tapping with a red-hot needle.

Dr. Little, of Philadelphia, also spoke of a case improved after tapping.

SECTION VI.—*On Diseases of Children.* Dr. A. Jacobi, of New York, Chairman; Dr. T. M. Rotch, Boston, Secretary.

A paper was presented by Dr. H. J. Bowditch, of Boston, on "The Relation between Growth and Disease," in which the rate of development was mentioned as throwing light upon the causation and treatment of children's diseases. He advocated frequent weighing of children, a progressive loss of weight indicating the approach of some sickness. The subject is to be considered by the National Board of Health, which will distribute blank cards for statistical information, some of which were exhibited by the lecturer.

Dr. S. C. Busey, of Washington, presented a paper by Dr. White, of Boston, "On some of the Causes of Infantile Eczema, and the Importance of Mechanical Restraint in its Treatment."

Dr. L. D. Bulkley thought that the author had laid too great stress upon the local treatment, and had ignored hygienic and other means. He approved of the disuse of water, but had never been obliged to resort to the mask.

Dr. Busey read a paper on "The Relation of Meteorological Conditions to Diarrhœal Diseases of Children."

Dr. H. O. Marcy exhibited some elastic double canula injection-tubes for irrigation of stomach, rectum, bladder, vagina, etc.

Dr. D. H. Goodwillie, of New York, read a paper, illustrated by means of a model, on the method of preventing thumb-sucking. The treatment recommended consists in breaking up the habit by applying a leather pad to the elbow, preventing the hand from coming to the mouth.

Coexisting nasal catarrh should be treated by douches and the application of powder blown into the nose, proper food, clothing, and rest.

His conclusions were as follows:

(1.) Thumb-sucking is more disastrous to the health of the child than the sucking of the other fingers, for, the thumb once in the mouth, it more readily remains during sleep.

(2.) It interferes with the child's proper rest, which should be continuous and undisturbed, and so becomes a source of nervous irritation and exhaustion.

(3.) It interferes with the natural respiration through the nose, and sets up abnormal conditions.

(4.) It malforms the anterior part of the mouth, and affects future mastication.

SECOND DAY'S PROCEEDINGS.

The amendment to the Code of Ethics, which at the last meeting was made the order of the day for this session, was brought before the Association by the President. The amendment (to Article I., Paragraph 1st) read as follows: "and hence it is considered derogatory to the interests of the public and the honor of the profession for any physician or teacher to aid in the medical teaching or graduation of persons knowing them to be supporters and intended practitioners of some irregular and exclusive system of medicine."

After a motion to table the amendment had been voted down, the subject was laid over until the next morning.

PUBLICATION OF PROCEEDINGS.

Dr. John H. Packard, chairman of the committee to whom the recommendations of the late President's annual address were referred, made an interesting report, concluding with the following resolution:

"*Resolved*, That the President be authorized to appoint a committee of five to digest and report in detail as soon as practicable upon the time, place, and terms of the publication of such a journal, to elect an editor, fix his

salary, and to arrange all other necessary details."

After some discussion, Dr. Davis moved to strike out so much of the resolution as related to the election of an editor. Adopted. On motion, the secretary and treasurer were added to the committee.

Dr. Toner offered a resolution instructing the secretary to publish, with the forthcoming report of the Transactions of the Association, the index of the proceedings of all the previous meetings. Adopted.

Dr. William Pepper, chairman of the Section on Medicine, read an able address, discussing recent theories of disease, and suggesting that many conditions now considered as typical of blood-poisoning might be due, as originally taught by Broussais, to some internal morbid condition, such as inflammation of mucous membranes, chiefly catarrhal in character.

The chairman of the Section on Obstetrics, Dr. Chadwick, of Boston, read his address upon the Advance of Obstetrics and Gynæcology during the past five years, which contained a valuable résumé of interesting cases, important operations, and statistics of publications in this department of practical medicine.

Both addresses were referred to the Committee of Publication.

Dr. J. M. Toner, from the Committee on Necrology, presented his annual report, which was referred to the Committee of Publication.

PROCEEDINGS IN THE SECTIONS.

SECTION I.—*Practice of Medicine, Materia Medica, and Physiology.* Dr. Wm. Pepper, Philadelphia, Chairman; Dr. T. A. Ashby, Baltimore, Secretary.

By appointment, Dr. King read a paper by Dr. Prentiss, of New York, entitled "Is Croupous Pneumonia a Zymotic Disease?" after which Dr. Dabney read a paper on "The Nature and Treatment of Pneumonia," which elicited an animated and prolonged discussion, without any general agreement, upon the subject of the etiology of pneumonia.

Dr. Robinson, of New York, being absent, his paper was read by title, "On the Nature and Treatment of Pulmonary Phthisis," and referred to the Publication Committee.

Dr. L. Duncan Bulkley, of New York, presented a paper on the "Diet and Hygiene of Eczema," which was deferred until the next afternoon.

SECTION II.—*Surgery and Anatomy.* Dr. Hunter McGuire, Chairman; Dr. Duncan Eve, Secretary.

Dr. Charles F. Stillman, of New Jersey, read a paper on a "New System of Surgical Mechanics," and presented a number of splints. He summed up the advantages of his system as follows. 1. Extension at any angle with motion. 2. Extension at any angle with luxation. 3. Fixation. 4. Motion complete or limited, constant or occasional. 5. Exposure of surface about the joint, admitting compression, elastic or otherwise; hot and cold applications; blisters; dressings; and easy inspection.

Dr. Alfred C. Post, of New York, read a paper on "Plastic Operations on the Face," and reported two cases. The first case which he related was one of epithelioma, involving the left side of the face, about fifty-five millimetres in diameter, extending above to a line within six millimetres of the margin of the lower lid, and below to a line midway between the ala of the nose and the angle of the mouth. The patient was a man 61 years of age. Dr. Post operated by making a horizontal incision separating the morbid growth from the lower lid, and another parallel incision below the tumor, connecting the two by vertical incisions before and behind. He then dissected up from the adjacent parts the diseased mass included between the four incisions, leaving a quadrilateral chasm, nearly of a square form. The two vertical incisions were then extended downward, the anterior one to a little below the base of the lower jaw, and the posterior one nearly as low as the base of the jaw. From the inferior extremities of these two vertical incisions, curved incisions, with their concavities looking backward and upward, were made to the extent of five centimetres, including between them a peduncle of skin and subjacent tissues for the nourishment of the extensive flap. The flap was then drawn up and secured by sutures so as to fill up the whole space left vacant by the removal of the disease. The wound healed throughout, leaving the patient but slightly disfigured.

The second case was one of absence of the upper lip and of the columna nasi, as well as of a portion of the right ala nasi, occasioned by the application of a caustic paste for the removal of a supposed cancer of the upper lip. The patient was a man 65 years of age. Dr. Post operated on the 1st of May, 1880. He commenced by separating from the cheek a small remnant of the upper lip, which remained at the left extremity, and reversing it so as to form a columna for the nose. He then made two horizontal flaps from the cheeks with peduncles carved downward and forward, and united them by means of pins and sutures, so as to reconstruct the upper lip. A number of supplementary operations were required, and the result was a marked improvement in the appearance of the patient.

Water-color drawings were exhibited, showing the conditions of these two patients before and after the operations, which showed the benefit and added much to the interest of the paper.

Dr. D. H. Goodwillie, of New York City, read a paper on "Treatment of Arthritis of the Temporo-Maxillary Articulation," in which

he reported cases treated. The causes of arthritis are local and constitutional. Whenever it occurs, the motion of the jaws becomes impaired according to the cause, severity, and length of the disease, and they often require long treatment in order to restore the muscles to their normal condition.

The treatment is by means of apparatus to relieve the joint of pressure on the inflamed articular surfaces. It is made as follows. An impression of the teeth of the entire jaw is taken, and an interdental splint made, the posterior part of which is thickened a little, for the purpose of a fulcrum.

Another impression is taken of the chin, and a rubber splint is made to fit it. A skull-cap is next made to fit the head closely, with elastic bands on each side passing down from it and fastened to the chin-splint.

The interdental splint is placed in position in the mouth, and the back teeth of the jaw closed on the fulcrum of the interdental splint; then, when pressure is made on the chin by tightening the elastic bands connecting the skull-cap with the chin-splint, the joint is relieved from pressure.

Dr. Moore, of Rochester, called attention to cases where cicatricial bands caused the trouble,—division of which usually cured them.

Dr. S. D. Gross, of Philadelphia, had seen comparatively few such cases since the abuse of calomel has ceased. He had not been able to accomplish much with wedges. Alluding to section of the bone, he said he had several times performed the operation.

Dr. Hunter McGuire, of Richmond, Virginia, said that one of the cases alluded to by Dr. Goodwillie afterwards fell into his hands. The case was not cured. There was no motion whatever. Dr. McGuire took out a wedge-shaped piece of bone just at the angle, and the result was good. He also spoke of a case of eleven years' standing, where a bridge of bone passed from the upper to the lower jaw, treated in a similar manner by excision of the bridge of bone.

Dr. L. A. Sayre exhibited the mode of applying a plaster jacket to a case of lateral curvature.

On motion of Prof. Gross, a vote of thanks was passed to Dr. Sayre. In discussing the method, Dr. Hodgen, of St. Louis, criticised the jury-mast, and said that it affected the growth of the jaw, which Dr. Sayre said he had never observed. Dr. Hutchison, of New York, spoke in favor of his method of treatment of hip-disease over that by the wire breeches.

The Chair appointed Drs. Kinloch, of South Carolina, Pratt, of St. Louis, and Burgett, of New York, as members of the Prize Award Committee.

SECTION III.—*Obstetrics and Diseases of Women.* Dr. J. R. Chadwick, Boston, Chairman; Dr. J. T. Johnson, D.C., Secretary.

A prolonged discussion was held upon the nature of the investment of uterine fibroids. Dr. H. P. C. Wilson, of Baltimore, then exhibited his uterine dilator and other instruments, which gave an opportunity for a protest from several members against instrumental interference with the uterus upon too slight grounds, betraying a reaction against the common resort to dangerous procedures upon trivial excuses.

Dr. H. O. Marcy exhibited his double drainage and injection tubes, by invitation from the Chair.

SECTION IV.—*On State Medicine*, etc. Dr. J. S. Billings, Chairman; Dr. R. J. Jennings, Secretary.

Prof. J. L. Cabell read a paper on "The National Board of Health and the International Sanitary Conference of 1881." After a historical sketch of the labors of the National Board of Health and of the conference which met in Washington last January, Dr. Cabell concluded as follows:

"There is, therefore, good reason for hoping that an international agreement may be arrived at between the States most frequently threatened with epidemic invasions. Aside from this, the degree of attention which, as a result of the deliberations of the conference, has been given to the subject of maritime sanitary police, cannot be without fruit in securing greater cleanliness, better ventilation of ships sailing on the high seas, and, in general, an improved sanitary condition of these important instruments of commerce, which become so often the carriers of the most deadly contagion, from the failure to use such precautions as sanitary science suggests, and as it is hoped will now be enforced among the maritime powers of the world."

Dr. C. F. Folsom, of Boston, read a paper on "The Relation of the State to the Insane," in which he compared the present methods of the treatment of the insane with those formerly in vogue. He also gave valuable statistical information as to the number of insane in various sections of the country; and he argued in favor of the establishment of State Lunacy Boards. Among the points made were, first, a Lunacy Board should embrace men with a thorough knowledge of insanity and its treatment. The chief duties of this board should be to secure proper care for those unfortunate insane who are kept in private dwellings, where they are very much liable to neglect. Secondly, they should require the commitment of lunatics to the asylum, and otherwise look into the cases, so as to be able to decide whether the lunatics should be retained for care or be discharged.

The paper was in every respect an able and thoughtful one, and full of information.

In discussing the paper, Dr. Grissom made the point that if insanity is treated promptly it is comparatively curable; but the usual custom is to delay action too long. One rea-

son of this is that some people seem to think it disreputable to have it known that they have an insane person in the family. When insanity becomes generally recognized as a purely physical disease and is so treated, a different feeling in regard to it will prevail, and a better prognosis will be afforded.

SECTION V.—*Ophthalmology, Otology, and Laryngology.* Dr. D. S. Reynolds, Kentucky, Chairman; Dr. S. M. Burnett, Washington, Secretary.

Dr. Carl Seiler, of Philadelphia, read a paper on Syphilitic Laryngitis, in which he discussed the diagnosis and treatment. He stated that the affection could be diagnosticated from non-specific inflammation by the peculiar discoloration of the mucous membrane and the symmetrical disposition of the inflammatory patches. There are frequent ulcerations of the larynx, which may be divided into shallow ulcers (in nothing differing from those seen in catarrhal laryngitis), and deep ulcerations, which were, in the author's opinion, due to the breaking down of the smaller or larger gummata in the mucous membrane. He also stated that a diagnostic sign of syphilitic laryngitis was seen in the red lines, and surrounding areola best observed upon the velum palati. He recommended as treatment (besides the systemic, with iodide of potassium and mercury, and supportive, with tonics, etc.), local touching of the shallow ulcers with solid nitrate of silver fused upon an aluminium probe, and the deep ulcers with acid nitrate of mercury (1 to 4), or the galvanic cautery.

In the discussion, Dr. Reynolds said that he thought constitutional treatment would do more good than any local measures. He was surprised at the statement of Dr. Seiler, that the diagnosis of simple from syphilitic laryngitis was difficult. He did not believe that catarrhal inflammation could produce ulceration. There were three kinds of syphilitic ulcers, viz.:

1. The ulcer with inflamed base and everted edges.

2. Ulcer with pale or gray base, with irregular margin and sharply defined scarlet areola.

3. Ulcer wholly unaccompanied with any evidences of inflammation, with sharply-defined outlines, and gummatous deposits surrounding the margin.

He thought that local applications could give no good results, unless restricted to such remedies as would give relief from pain.

The subject was also discussed by Drs. Stephens and Walsh.

Dr. Chisolm, of Baltimore, read a communication on a form of Tinnitus Aurium, due to rhythmical contraction of the tensor tympani, coming on at intervals in the day, resembling the fluttering of the eyelid. Treatment was unsatisfactory. In one case the omission of wine at dinner gave permanent relief.

Dr. Eugene Smith, of Detroit, reported a case of blepharoplasty, in which transplanting of skin was performed (one and a half by two inches was the size of the portion taken from the arm).

Dr. H. Augustus Wilson, of Philadelphia, presented some compressed pellets of atropia for ophthalmic use. One containing one one-hundredth of a grain was sufficient to relax the accommodation in an hour.

Just before adjournment, a paper by Dr. Laurence Turnbull, of Philadelphia, entitled (1) Otitis Intermittens, with Observations upon the Use of Quinine in Diseases of the Ear; (2) On the Importance of Ear Examinations in Effecting Life Insurance, was, on motion, read by title, and referred to the Committee on Publication.

SECTION VI.—*Diseases of Children.* Dr. A. Jacobi, New York, Chairman; Dr. T. M. Rotch, Boston, Secretary.

Dr. Jacobi made some introductory remarks upon eczema in infants, and advocated the use of restraint to prevent scratching. No water should be used, except in very rare contingencies. Scabs should be removed by alkaline lotions or Hebra's soap, to be followed by astringents, such as zinc ointment or diachylon. Attention to diet is of great importance, and often the children thrive better on artificial food than on breast-milk.

Dr. Jacobi, in the absence of Dr. R. J. Nunn, of Savannah, read a paper for him on the Treatment of Diphtheria. The disease had raged in Savannah with very fatal effects, and a letter from a friend elsewhere said that, after treating six hundred or seven hundred cases, his faith in the efficacy of drugs was very feeble. The causative influences are probably not the same in all cases. Medicines which cure the disease in Germany fail in this country; and the discussions as to the identity of croup, diphtheria, and scarlet fever are strong arguments in favor of this belief, and all treatment based upon one cause must fail to relieve all cases. Dr. Nunn quoted Dr. Jacobi as saying, "The entrance of the diphtheritic poison into the system is not the same in all cases. There are cases in which the origin of the disease is decidedly local. There are others in which the poisoning of the blood through inhalation is the first step in the development of the disease." A powder highly recommended and used is as follows:

℞ Sulphur. sub., gr. xlviij;
Acid. tannic., gr. xij;
Acid. salicylic., gr. i;
Pulv. potass. chlor., gr. xij. M.

Precaution must be used in compounding this prescription. A little of this powder is put on the back of the tongue every hour or two, and a small piece of ice given afterwards. It will be seen that this prescription is a combination of antiseptics principally.

In another case the following formula was used with good effect:

℞ Sulphur., gr. vij;
Acid. boracic., gr. iv;
Acid. tannic., gr. j;
Acid. salicylic., gr. j;
Resorcin., gr. j. M.

Another formula is:

℞ Sulphur. sub., gr. viij;
Acid. boracic., gr. iv;
Acid. benzoic., gr. j;
Acid. salicylic., gr. j;
Acid. tannic., gr. j;
Acid. tartaric., gr. iv;
Sodii chlorid., gr. iv;
Resorcin., gr. j. M.

Dr. Lathrop, of New Hampshire, said that he had experimented with chloroform largely, and finds it a highly useful agent. He uses it in diphtheria and other throat-affections, applied on a piece of cotton attached to a tube or pen-holder. The patients usually required visiting no longer than four days; but the cases were not so malignant as had been reported in other localities.

No unpleasant effects have ever followed this plan of treatment, and the child, in true diphtheria, does not complain of *smarting* from the application of chloroform. He had used this plan of treatment in one hundred cases. Of course constitutional measures are added.

Dr. William Lee, of Baltimore, has used equal parts of tinct. ferri chlorid. and ol. ricini with benefit. He considers the disease as local at first, and then constitutional. A physician from his county had used large doses of ol. copaibæ with benefit, followed by emetics to remove the membrane.

Dr. G. Vivian, of Minnesota, has used in severe epidemics alcohol as an inhalation, and has employed as much as a quart of alcohol a day. He has never seen any constitutional effects ensue.

Dr. J. McNeal, of Gettysburg, Pa., recommends the following: Potass. bromid., ʒj; potass. chlorat., ʒij; acid. carbolic., gr. xx; aquæ, Oj. Use in an inhaler. Locally, chloroformi, ʒij; lin. saponis, ʒj–ʒij.

Dr. F. E. Hitchcock, of Rockland, Maine, uses equal parts of sulphurous acid and water in an atomizer. The proportions can be varied, and the acid used as a gargle, with cold affusion externally.

Dr. Jacobi, in answer to an inquiry concerning the benefit of pilocarpin, said that his opinion of it was unfavorable. It was proposed as a specific by a Dr. Guttmann; and, while on this subject, he would state that this gentleman was not Dr. Guttmann, of Berlin. His article on pilocarpin had struck him as nothing more than an advertising arrangement. In diphtheria there are two forms, one in which the deposit can be readily separated from the mucous surface beneath, and one in which the deposit is deeply imbedded in the lower structures. In the latter form Dr. Jacobi believes that pilocarpin does harm, and in one case he thinks that death was hastened by using this drug. Pilocarpin debilitates the heart's action, often giving rise to nausea and vomiting. The milder cases of diphtheria recover, as a rule, if left alone; and in all cases of the disease he thinks the utility of pilocarpin doubtful. The paper in which pilocarpin was recommended as a specific is not satisfactory as regards the description of the cases treated. If the remedy be used at all, a fluid extract is the best preparation, as the muriate of pilocarpin is decomposed in the stomach. His opinion also of the effect of lime was not so high as that of many writers.

Dr. E. H. Bradford presented a paper entitled "Resection of the Tarsus in Severe Cases of Club-Foot." The first case was that of a girl eleven years old, with severe equino-varus, the axis of the foot being at right angles with that of the leg. Tenotomy and mechanical treatment were tried for a month, with but slight benefit. Dr. Bradford removed a wedge-shaped section of bone from the tarsus with a metacarpal saw, and with antiseptic precautions. There were no constitutional symptoms after the operation (except that the temperature rose once to 101°, being otherwise normal during the recovery), and in five weeks the patient was able to walk without a cane. The second case was one of a boy thirteen years old, with club-foot, in which an equally good result was obtained after operation.

THIRD DAY'S PROCEEDINGS.

After the announcement of the names of additional delegates, Dr. Hunter S. McGuire, of Virginia, as chairman of the Section on Surgery, read an address upon "Operative Interference in Gunshot Wounds of the Peritoneum," urging surgical interference, free drainage, etc.

Dr. John S. Billings, by vote of the Section on State Medicine, read the paper presented yesterday to the Section, "On Some of the Results of the Tenth Census, as regards Mortality Statistics."

Dr. N. S. Davis submitted a report on "Clinical Observations and Records." The report was accompanied by a recommendation that a committee of five be appointed by the President of the Association, to be called the Standing Committee on Atmospheric Conditions and their Relation to the Prevalence of Diseases; also suggesting how the committee shall be appointed, etc., and that five hundred dollars be appropriated for expenses. The recommendations were adopted.

OFFICERS FOR 1881.

Upon a question of privilege, Dr. Sayre, of New York, requested that the minutes of the session of 1877 be so amended as to contain his protest against a resolution adopted in the Surgical Section in regard to shortening after

fracture of long bones, which, he explained, was sent to the secretary of the Association, and not to a Chicago newspaper, as had been publicly asserted. The amendment was ordered to be made, in accordance with the explanation.

Dr. Stone submitted the report of the Committee on Nominations, as follows: For President, J. J. Woodward, U. S. A., of Washington; First Vice-President, I. P. O. Hooper, of Arkansas; Second Vice-President, Leartus Conner, of Michigan; Third Vice-President, Eugene Grissom, of North Carolina; Fourth Vice-President, Hunter McGuire, of Richmond; Secretary, William B. Atkinson, of Pennsylvania; Treasurer, R. J. Dunglison, of Pennsylvania; Librarian, William Lee, of Washington, D.C.; Chairman of the Committee on Arrangements, Dr. Stone.

Vacancies in the Judicial Council were filled by the appointment of Dr. S. N. Benham, of Pennsylvania; Dr. J. M. Jones, of the District of Columbia; D. A. Linthicum, of Arkansas; William Brodie, of Michigan; H. D. Hollon, of Vermont; A. B. Sloan, of Missouri; and R. Beverly Cole, of California.

St. Paul, Minnesota, was selected as the next place of meeting.

On motion of Prof. Gross, the rules were suspended. He then offered a resolution to establish a Section on Dentistry, which, as an amendment, was duly laid over until next meeting.

The amendment to the Code of Ethics was then again taken up for discussion: "and hence it is considered derogatory to the interests of the public and honor of the profession for any physician or teacher to aid in any way the medical teaching or graduation of persons knowing them to be supporters and intended practitioners of some irregular and exclusive system of medicine."

Dr. Davis made an earnest speech in support of the amendment. He was followed by Dr. M. P. Martin, of Massachusetts, also in support of the amendment.

A motion to lay the subject on the table was lost,—ayes 106, noes 108. The matter was again postponed, and made the special order for the next morning, immediately after the meeting of the Association.

The following amendment to the by-laws, offered by Dr. J. M. Keller, of Arkansas, then came up and was adopted:

"In the election of officers and appointment of committees of this Association by the President, he shall be confined to members in actual attendance, except in the Committee on Arrangements."

PROCEEDINGS IN THE SECTIONS.

SECTION I.—*Practice of Medicine.* Dr. L. D. Bulkley finished his paper on the Diet and Hygiene of Eczema, which he regarded as of great importance in treatment.

Dr. Whitaker, of Cincinnati, read a communication on the Treatment of Diphtheria, in which he recommended the use of antiseptics, such as quinine, salicylic acid, and the benzoates, and the local application of the officinal solution of the subsulphate of iron.

Dr. J. A. Octerlony presented a paper on the Treatment of Dysentery, which was referred.

Dr. I. E. Atkinson read a paper on "The Production of Albuminuria by the Use of Iodide of Potassium in Syphilitic Disease," which led to an interesting discussion.

Dr. H. Augustus Wilson showed his hypodermic pellets.

Dr. Henry A. Martin read a paper on Variola Vaccina and Variola Equinæ in Massachusetts, in which he reported a true case of spontaneous *variola equinæ*.

In conclusion, he moved that this Section recommend to the Association that a committee be appointed to visit these various farms and investigate the whole subject of bovine virus. Carried.

"The Materia Medica of the Future" was the title of a paper read by Dr. T. E. Stewart, of New York, and referred.

The following resolution, offered by Dr. Dunster, was adopted:

"*Resolved*, That the spirit of the Code of Ethics forbids a physician from prescribing a remedy controlled by a patent, copyright, or trade-mark. This, however, shall except a patent upon a process of manufacture or machinery, provided said patent be not used to prevent legitimate competition; and shall also except use of a trade-mark used to designate a brand of manufacture; provided that the article so marked be accompanied by working formulæ, duly sworn to, and also by a technical, scientific name under which any one can compete in the manufacture of the same."

Dr. Upshur, of Richmond, Virginia, read the report of a case of paralysis of motion of both upper extremities, in which the prominent symptoms were complete paralysis of motion of both upper extremities *except in the hands*, intense pain in the shoulders on any attempt to lie down, and inability to sleep. The attack was ushered in by convulsions epileptic in character.

SECTION II.—*Surgery and Anatomy.* Dr. Hunter McGuire, Chairman; Dr. Duncan Eve, Secretary.

Dr. B. A. Watson, of Jersey City, read an essay entitled "An Experimental and Clinical Inquiry into the Etiology and Distinctive Peculiarities of Traumatic Fever." After a historical résumé, he proceeded to define "traumatic fever," which he regarded as a term often used improperly for "septic fever." Modern investigations lead us to admit the existence of two varieties of fever after wounds, a septic and a non-septic variety. In a series of physiological experiments upon rabbits, in which he succeeded in lowering the temperature by injections of ether, chloroform, or car-

bolic acid, in most cases absorption of the fluid and swelling took place without a rise of temperature; in the exceptional case abscess with septic poisoning, and death, resulted. After these careful experiments, the writer is convinced that the fever was not due to the lesion, and raised the question as to whether or not it is due to the absorption of carbolic acid. The carefully-made experiments of Edelberg apparently demonstrated that the traumal fever noticed in connection with the antiseptic treatment should be attributed to the partly congealed and partly fluid blood rather than to the carbolic acid. After reviewing the question thoroughly, Dr. Watson is confident that primary "antiseptic" fever is due to carbolic acid acting on the wound-secretion, aided by the air; whilst absorption always precedes true septic phenomena.

The paper was discussed by Drs. Campbell, Nancrede, Post, Quimby, and others.

Dr. Charles A. Leale read a paper on "Malignant Pustule, or Labial Carbuncle," for which he advocated free incisions and thorough cauterizing the cut surfaces with nitric acid, subsequently treating it as an open wound with balsam of Peru.

On motion, a committee of three was appointed to select six subjects for discussion in the Section on Surgery at the next session of the Association.

SECTION III.—*Obstetrics and Diseases of Women.* The Chair announced the following committees:

Committee for Selection of Subject of Essay.—Prof. E. S. Dunster, Michigan; Prof. G. M. B. Maughs, St. Louis; Dr. H. M. Field, Boston.

Committee of Award.—Dr. Robert Battey, Georgia; Dr. Albert H. Smith, Philadelphia, Pa.; Dr. P. F. Mundé, New York City.

Committee to which Papers for Publication were Referred.—Dr. Joseph Tabor Johnson, Washington, D.C.; Dr. John Byrne, Brooklyn, N.Y.; Dr. H. P. C. Wilson, Baltimore, Md.

Dr. Joseph Tabor Johnson read a clinical inquiry entitled "Can we make a positive diagnosis of pregnancy previous to the occurrence of the audible sounds of the fœtal heart and the detection of the fœtal movements?" After citing the presumptive evidences of pregnancy, he concluded that the increased temperature of the vagina afforded a means of positive diagnosis of early pregnancy.

The paper was generally discussed.

Dr. Robt. Battey, of Georgia, was surprised that no gentleman had mentioned any of the following aphorisms in doubtful cases:

1st. Always consider a married woman pregnant if living with her husband until *proved* otherwise.

2d. Always consider an unmarried woman innocent till *proved* guilty.

3d. Always believe that a woman married, of the highest character, living with a husband of equally high character, both solemnly assuring the medical man that no intercourse has taken place for two years, as she has been bedridden for that length of time, may bring forth a dead fœtus.

4th. Always believe a young unmarried woman with abdominal tumor, of high social position and unimpeachable virtue, if she has been watched over by a platonic and abstemious young cousin of the male persuasion while the mother went out—to be pregnant.

Dr. P. F. Mundé, of New York, exhibited some instruments of original device, after which a discussion was entered into upon the subject of the management of the third stage of labor.

SECTION IV.—*Medical Jurisprudence and State Medicine.*

No papers were read before this Section; two were referred by title to the Publication Committee,—on "Cellars," by Dr. A. N. Bell, of Garden City, and on the "Necessity and Means of Removing Putrescible Matters from Inhabited Places," by Dr. W. Wright, of Milwaukee.

SECTION V.—*Ophthalmology, Otology, and Laryngology.*

The afternoon was devoted to the discussion of Astigmatism, by Drs. Reynolds, Risley, Burnett, Scott, and Daly.

A paper presented by the Chairman on the treatment of nasal polypi was read by title and referred.

SECTION VI.—*Diseases of Children.*

Dr. Blake, of Massachusetts, presented a paper on "Middle-Ear Disease in Children in the Course of the Acute Exanthemata."

Dr. Jacobi presented his address as chairman of the Section, in which special attention was given to the exanthemata. Rubeola (German measles) he considered fully entitled to a position among the contagious constitutional affections. In diphtheria he protested against the use of large doses of chlorate of potassium, as being dangerous, many fatal cases being on record. The paper was followed by general discussion.

Dr. Rotch, of Boston, said that, in order that there should be no confusion of terms, it should be first stated that there was a true measles and a rubeola (the rötheln of the German writers), as stated by Dr. Jacobi, and that so far as the eruption was concerned it was often impossible to make a distinction; secondly, that roseola, which was usually a papular eczema, had nothing to do with the other diseases, and that in the great majority of cases the eruption caused by eating crabs was that of urticaria, which of course was easily distinguished from the eruption of measles; thirdly, that he would again state that undoubted cases of true rubeola had been observed in Boston, where the disease is well recognized and differentiated from measles.

FOURTH DAY'S PROCEEDINGS.

The President announced the following Committee on Clinical Observations and Records: Drs. N. S. Davis, Chicago; J. M. Toner, D.C.; H. A. Marcy, Boston; W. H. Giddings, N.C.; S. M. Bemis, New Orleans.

THE ETHICAL AMENDMENT.

Dr. Billings, U.S.A., of Washington, submitted the following as a substitute for the amendment to the Code of Ethics which was under discussion yesterday: "It is not in accordance with the interests of the public, or the honor of the profession, that any physician or medical teacher should examine, or sign diplomas or certificates of proficiency for, or otherwise be specially concerned with the graduation of, persons who they have good reason to believe intend to support and practise any exclusive and irregular system of medicine."

Dr. Billings, in offering the paper, said, "This amendment has been prepared after consultation with the representatives of the various views which have been presented here, and it is believed to embody the prevailing opinion of the Association. It places no restriction upon teaching or upon the diffusion of knowledge, while it affirms the principle that we will not endorse in any way or recommend to the public men who limit their practice to one special dogma, or who deliberately class themselves with the vilifiers of and sneerers at regular medicine for the sake of notoriety."

The substitute, under the call of the previous question, was adopted.

The Committee on Nominations made their final report, naming the presidents and secretaries of the various Sections.

ABUSE OF MEDICAL CHARITIES.

The committee to which was referred the communication from the Philadelphia County Medical Society in reference to the abuse of medical charities reported the proposed plan of co-operation between the medical charities and Philadelphia Society for Organizing Charities to be admirably adapted, if faithfully carried out, to remedy the evil at which it is aimed, and which has reached such colossal proportions in that as in every large city both in this country and in Great Britain. As Philadelphia is exceptionally favored in having its systems of charity so admirably methodized and co-ordinated, your committee would suggest that in other cities not possessed of this machinery a concerted action of all the medical charities, in combination with the police authorities, in the matter of the visitation and registration of the dependent classes, might be attended with valuable results. The report concluded with the following resolution:

"*Resolved*, That the secretary be instructed to convey to the officers of the Philadelphia County Medical Society the acknowledgment of the indebtedness of this Association to the Society for thus bringing to our notice its action in a matter so nearly concerning the dignity of the profession and the welfare of the public."

The resolution offered yesterday by Dr. E. Dunster in the Section on Practice, relating to patent medicines, was referred to the Judicial Council.

The report of the treasurer showed a balance of two thousand and eight dollars and forty-six cents in his hands.

The librarian, Dr. Lee, presented an interesting report, and asked that two hundred dollars be appropriated for binding and purchase of books, and that the treasurer be authorized to subscribe fifty dollars to the *Index Medicus*, both of which were adopted.

On motion, one thousand dollars were appropriated from the treasury for the permanent secretary for his services during last year.

REPORT OF NOMINATING COMMITTEE.

The Committee on Nominations reported the following additional officers, who were elected:

I. *Section on Practice of Medicine.*—Chairman, Dr. J. A. Octerlony, Kentucky; Secretary, Dr. Deering J. Roberts, Tennessee.

II. *Section on Surgery and Anatomy.*—Chairman, Dr. J. C. Hughes, Iowa; Secretary, Dr. William A. Byrd, Illinois.

III. *Section on Obstetrics.*—Chairman, Dr. H. O. Marcy, Massachusetts; Secretary, Dr. C. V. Mottram, Kansas.

IV. *Section on Medical Jurisprudence and State Medicine.*—Chairman, Dr. A. L. Gihon, Washington, D.C.; Secretary, Dr. J. H. Sears, Texas.

V. *Ophthalmology, Otology, and Laryngology.*—Chairman, Dr. D. B. St. John Roosa, New York; Secretary, Dr. J. Solis Cohen, Philadelphia, Pa.

VI. *Diseases of Children.*—Chairman, Dr. S. C. Busèy, Washington, D.C.; Secretary, Dr. William Lee, Baltimore, Md.

VII. *Dentistry.*—Chairman, Dr. D. H. Goodwillie, New York; Secretary, Dr. P. W. Brophy, Illinois.

Judicial Council: Drs. S. N. Benham, Pennsylvania; J. M. Toner, Washington, D.C.; D. A. Linthicum, Arkansas; William Brodie, Michigan; H. S. Holton, Vermont; A. B. Sloan, Missouri; R. Beverly Cole, California.

Dr. D. S. Reynolds, of Kentucky, delivered the address of the Chairman of the Section on Ophthalmology, etc., which was appropriately referred. The reports of the committees on Necrology and secretaries of Sections were also presented. The report of the Section on State Medicine, containing a resolution offered by Dr. Martin, of Boston, recommending investigation of the vaccine farms and the methods of propagating bovine virus, was adopted, and a committee of three ap-

pointed for the purpose, and one hundred dollars appropriated for expenses.

Dr. William M. Beech, of Ohio, chairman, submitted the report of the committee appointed on social position of members of the medical staff of the army and navy, in which he asked that the committee be continued. In doing so, he argued that the principle of promotion which prevails among army officers and in the other departments of the government should be extended to the medical staff.

On motion of Dr. Davis, the matter was laid on the table.

RESOLUTION OF THANKS.

The Convention passed a resolution of thanks to the Committee of Arrangements of this Association, for the faithful attention they have given to their duties and requirements; to the medical profession and citizens of Richmond, for their hospitality and endeavors to make the meeting pleasant and agreeable; to Drs. McCaw and McGuire, for the elegant special entertainment given by them at the Westmoreland Club; to Mr. McClure, superintendent of the Telephone Company, for special facilities given the Committee of Arrangements and the Association; to Vice-President Parsons, of the Richmond & Alleghany Railroad, to Mr. Powell, manager of the Richmond Theatre, and to others, who had contributed to the pleasure and comfort of the members.

President Hodgen, in a short speech, then declared the Association adjourned.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

AT a conversational meeting of the Society, held at the Hall of the College of Physicians, Philadelphia, February 23, 1881, Dr. Albert H. Smith, President of the Society, in the chair, Dr. E. T. Bruen read a paper entitled "Clinical Notes Relative to Physical Diagnosis" (see p. 513).

DISCUSSION.

Dr. F. P. Henry remarked that the fact of Dr. Bruen having reported in succession cases of pleurisy with effusion and thoracic aneurism very naturally recalled to his mind a case illustrating that form of disease that is most apt to be mistaken for thoracic aneurism. He referred to pulsating empyema. The affection is an extremely rare one. Dr. Henry had met with but one case, and in medical literature had found recorded, with full details, but three others. These three were reported by Mr. MacDonnell in the *Dublin Journal of Medical Science* for March 1, 1844, and the term "pulsating empyema," as applied to cases of empyema attended with one or more circumscribed, strongly-pulsating tumors, was there first employed.

In Dr. Henry's case there were three strongly-pulsating tumors,—one in the left mammary region, about the size of half a large orange; a second, much smaller, and more acuminated in shape, in the left antero-lateral region; and a third, the largest of the three, in the left postero-inferior region, its long diameter, about four inches, corresponding with that of the vertebral column. All three of these tumors possessed a strong, systolic, expansile pulsation. The patient was a female, aged about 30, who was admitted to the Episcopal Hospital by Dr. Henry in the spring of 1880. The day after admission, pus was withdrawn from the smallest tumor by a hypodermic syringe. The next day, aspiration was performed, and some time after, a drainage-tube was inserted by Dr. John Ashhurst. The woman is still alive, and an inmate of the Hospital. Further details are now withheld, as the notes of the case will probably soon be published in full. The object of this premature and imperfect announcement with regard to it, apart from its manifest bearing upon the subject of Dr. Bruen's paper, is to inquire whether members of the Society have met with any similar cases.

Dr. H. Y. Evans said that a careful study of the sphygmographic tracings in aneurismal cases would throw light on the question of the contents of the sac: if nearly solid it would not give as abrupt a decline as where the contents are fluid.

Dr. J. T. Eskridge said that an Italian physician had declared that in purulent collection in the chest the vocal fremitus is entirely obliterated, but in serous effusion it is not absolutely lost. Dr. Da Costa had, in a certain case, based a diagnosis of empyema upon the entire absence of vocal fremitus. The vocal fremitus over the upper part of the chest is at the same time increased by the condensation and congestion of the lung, except where pulmonary emphysema coexists. He had never seen the Corrigan pulse except in cases of aortic regurgitation, though, if it did occur, there need be no fear of a mistake in diagnosis. In such cases, there is enormously-hypertrophied left ventricle; this hypertrophy does not occur in aneurism. Another point of distinction is the absence of retinal pulsation.

Dr. E. T. Bruen referred to a case of pulsating empyema where the observation was made that the pulsation was not transmitted from the heart; there was not the heaving pulsation of aneurism; but a needle introduced between the ribs only brought out blood and pus; this was repeated several times. This illustrates the difficulty of diagnosis. The statement that the transmitted pulsation in empyema is not so expansile as over an aneurism, he considered well founded, but recognized an especial difficulty in some cases of deciding the question after the acute symptoms have passed away.

With regard to vocal fremitus, he had seen cases of empyema in which it was preserved.

With regard to the sphygmograph, he had tried several kinds without complete satisfaction. Pond's is especially bad, because the weight on the end of the lever drags the needle backward so as to exaggerate the dicrotism. Marey's instrument yields better results.

The object of presenting this paper was to insist upon a systematic method of study of clinical cases: where a mistake is made, it is generally because the case has not been carefully studied, the diagnosis having been made from isolated symptoms.

On motion, the thanks of the Society were tendered Dr. Bruen for his interesting paper.

DISCUSSION UPON RÖTHELN.

Dr. Laurence Turnbull had recently seen a case very much like measles, but without catarrhal symptoms, which he thought must be German measles, or rötheln. It began with a slight rigor and fever, which was followed by enlarged glands over the mastoid region and in the neck, and by an eruption beginning upon the face and spreading rapidly over the whole body. The rash was not crescentic, and there was no marked elevation; it had an itching sensation, like a second vaccination. The eruption more resembled that of scarlet fever than measles.

Dr. Wittig said that the disease was not new, as he had seen it thirty years ago. Some cases show more effect upon the mucous membranes, others more upon the general surface; some have the inflammation of the conjunctiva like measles, others behave more like scarlatina. The kidneys are sometimes affected. Ordinarily, the disorder is not serious, and requires but little medication. Diluents, nitre, spirits of Mindererus, in some; in others, acidulated drinks are better, such as mineral acids.

Dr. O'Hara noticed a great difficulty in diagnosis in some cases. One case appeared the first day like one of malignant smallpox, on the second like scarlet fever, and on the third like measles. He subsequently concluded that it was German measles. In five or six days the attack had passed away.

The disease has a faint resemblance to smallpox. In only one case out of sixty had he noticed a resemblance to measles.

Dr. W. B. Atkinson based his diagnosis upon the rapidity with which the eruption spreads over the entire body. In six or eight hours the surface is covered, and it disappears just as rapidly. It requires very little treatment.

Dr. W. R. D. Blackwood had seen a great deal of measles, and had been able to distinguish this disease from it in only one case. The eruption spread rapidly, pulmonary symptoms were light, no coryza; but the child was extremely sick for a few days. There was considerable glandular enlargement in the axilla and groin, but especially in the post-cervical glands. Recovery took place in a few days.

Dr. E. T. Bruen mentioned a case where a child had measles, and, a year afterwards, had the typical eruption apparently, but without coryza or inflammation of the lungs. The eruption came out precisely the same in appearance, but the child did not seem very sick, and the disorder ran a mild course, desquamation occurring in ten days. This second attack he considered rötheln.

Dr. H. H. Smith asked if the disease is not called by the older writers *rubeola sine catarrho*.

Dr. Wittig said that it probably was. The name rötheln merely means that it is like roseola.

Dr. William M. Welch said that a great many cases of this character are received at the Municipal Hospital, being mistaken for smallpox. The disorder appeared to him to be very much like measles, but without the coryza. The eruption continues for several days, during which period the patients do not seem very sick. He had observed, in some cases, a temporary staining of the skin after the eruption had passed off.

REVIEWS AND BOOK NOTICES.

A System of Oral Surgery. By James E. Garretson, M.D. Philadelphia, J. B. Lippincott & Co., 1881.

Whether oral surgery be or be not a legitimate specialty in the eyes of the general surgeon, the appearance of the third edition of this book is evidence that there are practitioners of surgery, of medicine, or of dentistry who feel the need of more detailed instruction upon diseases of the mouth than is to be obtained from works on general surgery. The position of Dr. Garretson, as one who, originally a dentist, has passed from the narrower sphere to the wider outlook of a general surgeon, and has been successful in each career, of course eminently fits him to be the author of a treatise like the present. We think most of those who use Dr. Garretson's book will agree with us rather than with what *seems* to be his own opinion,—namely, that the most valuable part of the book is that which deals with practical points, and that when philosophy comes in, then his thought has some tendency to become metaphysical,—*i.e.*, intangible, and altogether above those lower regions of common sense in which a metaphysician withers as an exotic dies in a Northern winter. Take, as example, his chapter on tumors. Practically, his idea of diagnosing cancer by exclusion is often of value; scientifically, his division of tumors would probably never have been made by any one educated in strict scientific and not metaphysical or practical thinking.

But we are losing sight of the duty of one who notices a new edition of an old book,—namely, to compare it with the previous output. Of this volume we can say that it appears to us, in many ways, superior to its predecessor. It will no doubt enjoy the continued success it deserves, and sustain the reputation of its author.

LECTURES ON THE DISEASES OF THE RECTUM AND THE SURGERY OF THE LOWER BOWEL. Delivered at the Bellevue Hospital Medical College. By W. H. VAN BUREN, M.D., LL.D. Yalen., Professor of the Principles and Practice of Surgery in the Bellevue Hospital Medical College, etc., etc. New York, D. Appleton & Co., 1881.

The volume before us is a second edition of the lectures delivered by the eminent professor in Bellevue College. These lectures are twelve in number, and may be taken as an excellent epitome of our present knowledge of the diseases of the parts in question. The work is full of practical matter, but it owes not a little of its value to the original thought, labor, and suggestions as to the treatment of disease, which always characterize the productions of the pen of Dr. Van Buren.

It is, of course, impossible, within the narrow limits of a book-notice, to do more than allude to the contents of such a book. The first two lectures are devoted to the consideration of pruritus, eczema, and hemorrhoids, internal and external. The general symptoms of the latter complaint are graphically described, and the hygienic and palliative measures which should be resorted to are forcibly laid down. The use of nitric acid as a palliative remedy is restricted to hemorrhoids occurring in young full-blooded subjects, where there is a tendency to hemorrhage, and where the protruding surfaces are red, vascular, velvety, and limited in extent. The different processes for the radical cure of internal hemorrhoids are carefully considered by the author, who tells us that he has tried all of the measures employed to destroy these tumors, and can "confidently recommend to you strangulation by the ligature as the safest, surest, and most manageable procedure." The écraseur he objects to as being tedious, and as being sometimes followed by bleeding.

In performing the operation of ligation of hemorrhoids Dr. Van Buren differs somewhat from the practice of surgeons generally. He is not content with simply ligating the tumors, but insists strongly on thorough dilatation of the sphincter ani muscle at the commencement of the operation, by which process the interior of the lower portion of the rectum is placed entirely at his disposition. This stretching of the muscle, he tells us, saves much pain and trouble to the patient after the operation, for the muscle will not recover from its condition for a week, during which time the patient escapes pinching and pressure of the tender parts. There is probably, also, less tendency to retention of urine, which is often so annoying an accompaniment of operations for hemorrhoids. Dr. Van Buren states that he has employed this process of preliminary dilatation for the last twenty years, and "can say truly that I have never seen any permanent injury to the sphincter, nor, indeed, any inconvenience whatever, follow its use;" and he adds that he cannot help thinking that those who speak unfavorably of this measure may not have fully tried it. Dr. Van Buren speaks positively as to the danger of ligation of hemorrhoids in selected cases, and says that it is so trifling as scarcely to be appreciated. He has never had an unpleasant result, but he refers to one fatal case of Dr. Mott's and to one other fatal case. In both instances the death was from pyæmia.

The lecture upon prolapsus ani forms one of the most instructive and valuable chapters in the book. This affection the author divides into two varieties,—the complete and the incomplete. In the former the mucous membrane alone of the rectum descends; in the latter the muscular and serous coats of the bowel, and even other viscera, may also be included. This division corresponds with that of the late French authorities,—prolapse of the mucous membrane alone and prolapse with invagination, the latter containing all the coats of the gut. Dr. Van Buren also further subdivides complete prolapse into three varieties,—viz., the first, or most common form, in which there is no sulcus at the base of the tumor; the second variety, in which there is a sulcus; and the third form, in which invagination has occurred at some point higher up, and distant from the anus. The radical cure in a general way is to be brought about by setting up a process of repair and causing enough plastic exudation into the meshes of the loose submucous tissue of the rectum and anus to glue it fast to the subjacent muscular coat and sphincter, and to hold it there. This the author believes can best be effected by the actual cautery, especially by the use of the thermo-cautery of Paquelin, the instrument being applied in longitudinal and vertical stripes so as to prevent circumferential stricture.

We would like to follow the author through the chapters devoted to the study of abscess, fistula in ano, and fissure of the anus, but our limited space forbids. As to the propriety of the operation for fistula in phthisical patients, Dr. Van Buren says, "I would advise an attempt to cure a patient with physical signs of phthisis, provided there were no positively advancing softening or severe cough, because, in addition to stopping a waste, it would remove an impediment to exercise in the open air, possibly on horseback;" and in this opinion he believes that most practical surgeons concur.

The chapters on ulcer and stricture, and

on tumors and cancer of the rectum, and its general hygiene, are full of interest, and their perusal will well repay even the most busy practitioner.

The book as it stands in its new form is, indeed, a contribution alike worthy of its distinguished writer and creditable to American surgery.

CONTRIBUTION À L'ÉTUDE DU MÉCANISME ET DU TRAITEMENT DE L'HÉMORRHAGIE LIÉE À L'INSERTION VICIEUSE DU PLACENTA. Par DR. PAUL BITOT.

A CONTRIBUTION TO THE STUDY OF THE CAUSES AND TREATMENT OF HEMORRHAGE DUE TO AN ABNORMAL INSERTION OF THE PLACENTA. By DR. PAUL BITOT.

This valuable monogram of one hundred and seventy-eight pages is divided by the author into two parts, the first (containing fifty pages) being devoted to the causes, and the second (containing one hundred and twenty-eight pages) to the treatment, of the hemorrhage occurring in placenta prævia. Considerable space is given to the definition of abnormal insertion of the placenta. Portal receives credit for having first mentioned the possibility of the placenta being situated near the cervix where hemorrhage occurred without other evident cause; but Schlacher is said to have demonstrated the fact of such an implantation upon the cadaver of a patient dying of hemorrhage.

The author refers to the definition given by Barnes concerning normal and abnormal situation of the placenta, reproducing his diagrams as found in Barnes's "Obstetric Operations" illustrating the so-called fundal, meridional, and cervical zones. He makes three varieties of prævia: *complete*, when the centre of the placenta corresponds more or less exactly to the internal os; *partial*, when the placental edges reach the internal os; and *marginal*, when the placenta is situated in its vicinity.

He discusses the causes of hemorrhage during pregnancy, during labor, and after labor. In this connection he mentions the opinions formerly held with regard to the function of the cervix during pregnancy, and gives the theory of Bandl, which he says was first taught by Prof. Guyon. Special attention is given to the theory of Depaul, that hemorrhage is frequently dependent on irregularities in the development of the uterus; to that of Barnes, that hemorrhage is due, first to excess in rate of growth of placenta over cervix, and secondly to the increased congestion at the menstrual nisus; to that of Gendrin, who finds the cause of hemorrhage in pathological conditions of the placenta; and to that of Matthews Duncan, who believes hemorrhage due simply to the rupture of the utero-placental vessels from various causes.

The second portion of the book discusses the *treatment* of hemorrhage before, during, and after labor. He condemns the use of ergot before labor as advised by Dubois, admits the value of vaginal injections as recommended by Seyfurt, and praises highly the use of the tampon, for the introduction of which very minute directions are given and diagrams inserted to illustrate his method more clearly. He does not admit, however, with Wiegand and Holst, that it is entirely unproductive of local irritation. He considers the tampon when well applied the remedy *par excellence* for hemorrhage before or during labor.

Speaking of it during labor, he says that even should it not entirely check the hemorrhage (which is the exception) it restrains it and prepares the genital organs for labor by producing violent and repeated contractions of the uterus.

The treatment of hemorrhage during labor by rupture of the membranes was instituted, the author says, by Mauriceau, in 1688, and the honor is ascribed to Puzos of having introduced that method into general practice in France, Germany, and England. The indications and the contra-indications for this procedure are given, and a table of twelve cases treated "according to the method of Puzos" shows the recovery of mothers to be eighty-five per cent. and the proportion of children saved to be sixty per cent.

The *accouchement forcé*, the methods of Simpson, Barnes, and Cohen, the perforation of the placenta, the use of the forceps, and the operation of version, are discussed. Eight hundred and sixty cases of version performed for placenta prævia show a maternal mortality of thirty per cent.

The treatment of hemorrhage after labor is briefly considered, and nothing new suggested. The author says, "The administration of ergot during the last period of labor and immediately after delivery, internally (if the patient can tolerate it) or by subcutaneous injections in the form of ergotin, and the application of the tampon in combination with compression upon the uterus through the abdominal walls, constitute the most rational procedure."

A very excellent bibliography of the subject of placenta prævia is appended. G. W. L.

RELAPSE OF TYPHOID FEVER, ESPECIALLY WITH REFERENCE TO THE TEMPERATURE. By J. PEARSON, M.D., B.Sc., F.R.C.P. Lond., Assistant Physician to Charing Cross Hospital, Physician to the Victoria Hospital for Children, etc. With Temperature Charts. 8vo, pp. 144. London, J. & A. Churchill, 1880.

The greater part of the matter of this volume was contributed by its author to the *Medical Times and Gazette*, in a series of papers which appeared during the course of the year 1879. It is fortunate that these papers have been collected and given to the profession in a per-

manent form, for they constitute an important contribution to the knowledge of the natural history of typhoid fever, and mark a very considerable advance in the work of clearing up the obscure subject of typhoid relapse.

Since 1830, when relapses in typhoid fever were first described by Schultz, they have attracted the attention of many observers, but, partly by reason of the intrinsic difficulties of the subject and partly by reason of imperfect methods of study, not including systematic temperature-observations during the period of apyrexia intervening between the primary attack and the relapse, not only the pathology but even the sequence of phenomena going to form the clinical history of relapses of typhoid have continued to be involved in great confusion.

The author, coming to the clinical investigation of the subject from the stand-point of the temperature-changes, by which febrile disorders are to be first studied, has greatly systematized and rendered useful the disconnected facts brought to light by Stewart, Thierfelder, Griesinger, Ebstein, Wunderlich, Maclagan, and Da Costa. Much was previously known of typhoid relapse, as much may be known of the scenery of a play by viewing it from the rear of the stage: the scene can, however, only be appreciated as a harmonious and significant picture by regarding it from the proper point of view and well illuminated. It is thus that the author seeks to present to us his subject, by leading us to view it in the light shed upon it by systematic temperature-studies. His object has been in a great measure attained. That he has not wholly succeeded is due to difficulties in the subject as yet insurmountable,—by no means to faulty methods of work or lack of painstaking.

The first chapter is introductory to the subject, and is devoted to general descriptions of relapses and recrudescences, and an account of the plan of the work,—the *proposition*, in a rhetorical sense.

The second is devoted to single relapses, their temperatures, and their modifications by complications.

In the third chapter are considered irregular and complicated single relapses.

The fourth treats of cases in which two or more relapses recur, with or without complications.

The fifth includes recrudescences, intercurrent attacks, irregular relapses, and conditions likely to be confounded with relapse of typhoid fever.

The sixth chapter has to do with cases of fatal relapse.

The seventh and last is devoted to general conclusions and remarks,—*the peroration.*

I regret that my space in the pages of the *Times* prevents any adequate analysis of these chapters. They are written in a truly scientific spirit, and are of great importance to those who would extend their knowledge of our commonest infectious disease. This book is of more value to the thoughtful practitioner than many volumes of ready-reference-books and formularies of convenient prescriptions.

The reports of cases are made clear by a number of well-printed charts of temperature. Upon the page where stands a brief preface is the announcement of the death of its author at the time his book was ready for publication. To the regret that one capable of such excellent work has so soon ceased from his labors is added a thought of the mystery of life, as we look over the pages of a fellow-worker thus newly "gone over to the majority."

J. C. W.

GLEANINGS FROM EXCHANGES.

CASE OF PROGRESSIVE PAINFUL INFLAMMATION OF ARTERIES.—At a recent meeting of the Clinical Society of London (*Medical Press and Circular*, 1881, p. 315) Mr. John H. Morgan read notes of the following case:

G. W., æt. 46, contracted syphilis at 18, has since married, and has several healthy children. He is subject to a curious congenital enlargement of the superficial veins of the chest and abdomen. Nine years ago he was a patient at Guy's Hospital under Dr. Willis, who has described his case. In 1876 he suffered pain in the left armpit, which passed down to the bend of the elbow and then left him. In 1877 he came under Mr. Morgan's care suffering from pain in the left arm for which there seemed no evident cause. There was no swelling, and he soon recovered from this attack. In 1880 occurred an attack of sudden and severe pain in the right groin, deep-seated, and made intense when the part was pressed. The area of pain was confined to two to three inches in the course of the femoral artery, and to one to two inches on either side of it. This pain gradually travelled down in the course of the artery to the popliteal space, being traceable throughout, and being more severe at the part corresponding with the opening in the adductor magnus. In course of time the pain passed into the leg, and here some limited œdema was seen at the seat of pain, but not beyond. Similar pain came suddenly in the right axilla, and passed gradually down in the course of the brachial artery into the forearm, and here again a limited œdema occurred. He was treated with iodide of potash, alkalies, and biniodide of mercury, at various times and in varying quantities, but without material effect upon the disease. Subsequently the right carotid artery was affected in a similar way; the symptoms pointed evidently to disease of an artery,—probably inflammation of the fibrous coat,—since the pain passed from the centre to the periphery, was in the course of the various arteries, and was made intense

directly the finger perceived the pulsation of the artery beneath it. Mr. Morgan had not been able to find any record of observation of similar symptoms. The patient is now in good health, and has had no recurrence of the symptoms.

Flat-Foot in Young Infants.—An editorial article in the *Medical Times and Gazette* (vol. i., 1881, p. 349) quotes from a paper in the *Centralblatt für Chirurgie* by Professor Volkmann. The author alludes to the general belief that the comparatively supinated foot of young infants is converted into the more pronated form of adult age by the weight of the body. If this theory were true, says Volkmann, not only should children who do not learn to stand and walk at the proper time retain the infantile form of foot, but this condition ought to persist in healthy children until the period of standing and walking begins; but this is not the case. Even in the first months of life the foot begins to lose its fœtal form, and may have reached or even passed the normal adult shape before any attempt is made to put it to the ground. And it is also pointed out that in the not uncommon cases where a child, on account of disease or weakness, remains for fifteen or eighteen months without making any efforts at walking, we no longer find the fœtal form of foot remaining. Again, flat-foot may be developed before the end of the eighth or tenth month. Volkmann therefore concludes that body-weight in walking and standing has nothing to do with this change of shape, which depends rather upon hereditary influence. He shows that many changes in shape of bones take place between infantine and adult life, some independent of, some in opposition to, the forces above mentioned. An instance of the latter is the hollowing of the instep, which begins about the time the child begins to walk.

As to the special subject of flat-foot in young children, Volkmann attributes it to four principal causes, as follows. 1. Congenital, depending upon intra-uterine pressure. This form should be treated early and energetically. 2. That form which arises from a too rapid assumption of the adult shape of the foot. Treatment of this variety is invariably unsatisfactory. 3. Rickety flat-foot, which, though undoubtedly, as a rule, caused by the weight of the body, in some cases equally undoubtedly sets in before the child has made any attempt at walking. It seems, therefore, probable that the rickety process itself has an influence in determining the flattening of the plantar arch. 4. Paralytic flat-foot.

Chaulmugra Oil.—A recent editorial article in the *British Medical Journal* (vol. i., 1881, p. 475) says that it is most conveniently administered in capsules, but many patients take it well in milk, cod-liver oil, or almond oil. The usual dose is five to fifteen minims. It is best to begin with a small dose, and increase it gradually as the patient becomes accustomed to the medicine. The *perles*, as sold in the shops, contain four minims, and are convenient for use when the dose is to be frequently varied. Chaulmugra oil was first introduced as a specific for leprosy, and Dr. Liveing has published six cases thus treated which were decidedly benefited by its use. The dose given was as high as a drachm thrice daily, together with inunctions of the same in ointment containing twenty grains of the oil to an ounce of lard. In psoriasis, lupus, and obstinate cases of scabies and ringworm it has been used with success. Chaulmugra oil was also introduced as a remedy for phthisis, but the testimony as to its usefulness in this disease is conflicting. In chronic rheumatism and in rheumatic gout it is most useful. Here it is used alone as an embrocation, the after-smell, which is disagreeable, being covered by violet-powder. For neuralgia and sciatica chaulmugra oil is generally mixed with camphor and chloroform, or with an equal weight of a saturated solution of menthol in chloroform, and then rubbed over the painful part. It is found that children, as a rule, take the chaulmugra without difficulty; and its internal administration, combined with inunction, has been employed with benefit in scrofula and in cases of marasmus.

The Treatment of Pneumonic Fever (Acute Lobar Pneumonia) by the Employment of the Wet Sheet.—Prof. Flint (*Gaillard's Medical Journal*, March, 1881), in a clinical lecture on this subject, says that the treatment is as yet novel in this country, and, being desirous of investigating it, he selected for experiment cases of pneumonic fever where the disease was in an early stage, the patients apparently robust, the pyrexia considerable or high, and no complications existing. The directions were to employ the wet sheet whenever the axillary temperature exceeded 103° Fahr. The patient was wrapped in a sheet saturated with water at a temperature of about 80° Fahr., the bed being protected by an india-rubber covering. Sprinkling with water of about the same temperature was repeated every fifteen or twenty minutes. If the patient complained of chilliness, he was covered with a light woollen blanket, which was removed when the chilly sensation had disappeared. In none of the cases was the blanket used much of the time while the patient was wrapped in the wet sheet. The patient remained in the sheet until the temperature in the mouth fell to 102° or lower, care being taken to watch the pulse and other symptoms. When the temperature was reduced, the wet sheet was removed, and resumed if the temperature again exceeded 103° Fahr.

Prof. Flint's conclusions, drawn from the four cases, full notes of which he gives, indicate that in his opinion the treatment is not

only not hurtful, but the history of these cases renders probable the inference that the disease was controlled and brought speedily to a favorable termination by the treatment.

CASE OF MOVABLE LIVER.—Dr. Chvostek (*Lancet*, vol. i., 1881, p. 429; from *Wiener Med. Blatt*) notes the case of a man with whom nothing appeared to be wrong, and who gave no history of any violence whatever. When he stood up, however, the upper and posterior border of the liver was felt to come forward from under the margin of the thorax, and to be six centimetres and a half below the tip of the xiphoid cartilage in the right præsternal line. The left end of the liver was plainly felt through the abdominal wall, and from it the anterior or, rather, the lower edge of the liver could be traced arching down to the right, being in the middle line fifteen centimetres below the xiphoid process, and in the right nipple and axillary lines respectively seven and one-half to two centimetres below the edge of the thorax. The liver did not markedly descend on taking a deep inspiration. In the horizontal posture it could be replaced under the ribs to a considerable extent. In lying on one side the organ fell, to some extent, towards the dependent side. The lower edge of the suspensory ligament could be felt tightly stretched, but this produced no pain; and so completely absent were all symptoms that the condition was only discovered accidentally.

QUININE AMAUROSIS.—Dr. E. Gruening (*Archives of Ophthalmology*, March, 1881) collects the rather scanty literature of the subject, and adds a case of his own fully noted and with illustrative diagrams. He concludes as follows:

After reviewing the unequivocal cases of quinine-poisoning with amaurosis (Roosa, Wecker, Voorhies, Gruening), we find a remarkable congruence in their essential features. The patient, after the ingestion of a single dose or of repeated doses of quinine in varying quantities, suddenly becomes totally blind and deaf. While the deafness disappears within twenty-four hours, the blindness remains permanent as regards peripheric vision, central vision gradually returning to the normal after some days, weeks, or months. The ophthalmoscope reveals an ischæmia of the retinal arteries and veins, without any inflammatory changes.

In view of the constancy of these symptoms and the uniformity of the ophthalmoscopic picture, we are entitled to demand for this distinct type of amaurosis a recognized position in the pathology of the optic nerve and the retina.

VARICES IN PREGNANCY.—Mr. John Lucas, writing to the *Medical Times and Gazette* (vol. i., 1881, p. 358), says that not only has he seen the varicosity in the most usual part, the leg, but also in the hypogastrium, vulva generally, and labia majora and minora and clitoris in particular, and notably in one case which caused some anxiety. During the eighth month of utero-gestation accompanying anasarca there was frequent retention of urine; the cause of the latter, as suspected by Dr. Matthews Duncan (under whose care the patient came), was, Dr. Lucas thinks, varicosity and consequent anæsthesia of the bladder. Mr. Lucas suggests as possible the theory that albuminuria may be due to this cause, and even grave uræmic symptoms also. If so, catheterism and the retention of a gum-elastic catheter *in situ* through a diaper would be indicated, not merely for the relief of the bladder, but, moreover, for the prevention of those alarming symptoms from supervening.

SUCCESSFUL USE OF NITRITE OF AMYL IN WHOOPING-COUGH.—Dr. R. C. Bowles writes to the *Virginia Medical Monthly* (March, 1881) giving a brief account of a very severe case in a female infant of four months, in which the paroxysmal stage was unusually severe, threatening death by asphyxia at each attack. The lower jaw was clinched as in tetanus, there were violent but ineffectual efforts at respiration, the face black and turgid, the brain flooded with carbonized blood, the sphincters relaxed, involuntary discharges, and the child to all appearances lifeless. But a prompt resort to the usual means of artificial respiration revived it, when it continued tolerably well until the next paroxysm, to follow the same course. This continued for several days, and, having exhausted the list of antispasmodics without relief, Dr. Bowles commenced the use of the inhalation of the nitrite of amyl, with perfect relief of all the symptoms. By the eighth day of using the nitrite, with good doses of cinchona alkaloid, the child was convalescent. Without the nitrite, he is satisfied, it would have died.

MISCELLANY.

THE CARTWRIGHT PRIZE AWARDED TO A PHILADELPHIAN.—The Cartwright prize of five hundred dollars has been awarded by the New York College of Physicians and Surgeons to Dr. Frederick P. Henry, of this city, for his essay entitled "Observations with the Hæmacytometer upon the Globular Composition of the Blood and Milk."

NOTES AND QUERIES.

GRAND FALLS, VICTORIA COUNTY, NEW BRUNSWICK,
May 3, 1881.

EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—Knowing the interest you take in medical reform, I write to inform you that at the last session of our Legislature an act was passed entitled the "New Brunswick Medical Act," which, although susceptible of many improvements, is a great step in advance of our former law, or, rather, want of law. Among the important clauses is one requiring all who, after this, begin the study of medicine to practise in New Brunswick to pursue a four years' course, one of which may be under the direction of a duly registered

medical practitioner, but there must be a college course of three years. This will shut off from our students all but three or four of the American colleges, and will be a drop in the bucket of opinion which will finally drive the rest to adopt a better curriculum. All qualified men are required to register, and matters medical are controlled by a council of nine registered physicians (holding office for a term of years), four appointed by the Governor in Council and five by the New Brunswick Medical Society. The penalty for practising if not registered is twenty dollars for each day. Further idea cannot be given in the scope of a letter.

Yours, etc.,

G. Hayward Coburn.

THE WEST PHILADELPHIA MEDICAL SOCIETY.

The want of a representative medical body which has long been felt by the physicians of West Philadelphia has been met by the organization of this new Society. On Monday evening, April 25, 1881, there was a meeting of a large number of medical men at the Institute, Fortieth and Ludlow Streets, at which an appropriate constitution was adopted, elections held, and all necessary plans matured to put the Society at once into working order. The membership includes a very large proportion of the profession in West Philadelphia and vicinity. The stated meetings are to be held on the first Monday evening of each month. The following are the officers for the first year: President, Dr. Samuel S. Stryker; Vice-President, Dr. Charles A. McCall; Secretary, Dr. James Hendrie Lloyd; Treasurer, Dr. W. H. Wallace; Censors, Drs. Skillern, Girvin, and M. B. Musser; Executive Committee, Drs. J. H. Musser, Dixon, and Dulles.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM MAY 1 TO MAY 14, 1881.

Surgeons R. H. Alexander and C. T. Alexander and Assistant-Surgeon R. H. White are detailed as members of a Board, to meet at West Point, N.Y., June 1 proximo, to examine into physical qualifications of members of the graduating class and the candidates for admission to the Academy. S. O. 109, A. G. O., May 12, 1881.

King, William S., Colonel and Surgeon.—His extension of leave of absence on account of sickness, granted him November 9, 1881, from A. G. O., still further extended six months on account of sickness. S. O. 105, A. G. O., May 7, 1881.

McParlin, T. A.—His promotion to Assistant Medical Purveyor, with the rank of Lieutenant-Colonel, *vice* Cooper, deceased, confirmed by the Senate, May 10, 1881.

Bache, D., Major and Surgeon.—Relieved from duty in Department of California, to proceed to Philadelphia, Pa., and report by letter, on arrival, to the Surgeon-General. S. O. 104, c. s., A. G. O.

McClellan, Ely, Major and Surgeon.—To report to the Medical Director of the Department for duty until further orders. S. O. 56, Department of the Columbia, April 26, 1881.

Hartsuff, A., Major and Surgeon.—Relieved from duty in Department of the East, to take effect June 1, 1881, then to report in person to Commanding General, Department of the Missouri, for assignment to duty. S. O. 104, A. G. O., May 6, 1881.

Middleton, J. V. D., Major and Surgeon.—Relieved from duty in Department of the East, to take effect June 1, 1881, then to report in person to Commanding General, Department of the Missouri, for assignment to duty. S. O. 104, c. s., A. G. O.

Brown, J. M.—His promotion to Surgeon, with the rank of Major, *vice* McParlin, promoted, confirmed by the Senate, May 10, 1881.

Brown, J. M., Captain and Assistant-Surgeon.—Relieved from duty at Fort Garland, Col., and assigned to duty at Fort Lewis, Col. S. O. 86, Department of the Missouri, May 3, 1881.

Hubbard, Van Buren, Captain and Assistant-Surgeon.—Relieved from duty in Department of California, to proceed to New York City, and, on arrival, report by letter to the Surgeon-General. S. O. 104, c. s., A. G. O.

Gardner, W. H., Captain and Assistant-Surgeon.—Relieved from duty in Department of the South, to proceed to Washington, D.C., and report in person to the Surgeon-General. S. O. 104, c. s., A. G. O.

Caldwell, D. G., Captain and Assistant-Surgeon.—Relieved from duty at Fort Fred. Steele, Wyo., and assigned to duty at Fort Sanders, Wyo., as Post-Surgeon, relieving Assistant-Surgeon Kimball. S. O. 36, c. s., Department of the Platte.

Koerper, E. A., Captain and Assistant-Surgeon.—Relieved from duty in Department of the Platte, to proceed to Philadelphia, Pa., and, on arrival, report by letter to the Surgeon-General. S. O. 104, c. s., A. G. O.

Lippincott, Henry, Captain and Assistant-Surgeon.—Having reported at these Headquarters, is assigned to duty as Post-Surgeon at Fort Niobrara, Neb. S. O. 36, Department of the Platte, April 29, 1881.

King, W. H., Captain and Assistant-Surgeon.—Relieved from duty in Department of Dakota, and, on expiration of his present sick-leave of absence, to report by letter to the Surgeon-General. S. O. 104, c. s., A. G. O.

Kimball, J. P., Captain and Assistant-Surgeon.—Assigned to duty at Fort Sidney, Neb., as Post-Surgeon, relieving Assistant-Surgeon Moseley. S. O. 36, c. s., Department of the Platte.

De Witt, C., Captain and Assistant-Surgeon.—Relieved from duty in Department of the Platte, to proceed to Philadelphia, Pa., and, on arrival, report by letter to the Surgeon-General. S. O. 104, c. s., A. G. O.

Havard, V., Captain and Assistant-Surgeon.—Relieved from duty at Presidio del Norte, to proceed to Fort Concho, Texas, await there the arrival of Capt. Livermore, Corps of Engineers, and report to him by letter. S. O. 63, Department of Texas, April 28, 1881.

Moseley, E. B., Captain and Assistant-Surgeon.—Assigned to duty as Post-Surgeon at Fort Fetterman, Wyo. T. S. O. 36, c. s., Department of the Platte.

Maus, L. M., Captain and Assistant-Surgeon.—Relieved from duty in Department of Dakota, to proceed to Washington, D.C., and report in person to the Surgeon-General. S. O. 104, c. s., A. G. O.

Reed, W., Captain and Assistant-Surgeon.—Relieved from duty at Fort Henry, Md., and to report to the Commanding Officer, U. S. Barracks, D.C., for duty at that post. S. O. 76, Department of the East, April 29, 1881.

Shannon, W. C., Captain and Assistant-Surgeon (now awaiting orders in New York City).—To report in person to Commanding General, Department of the Platte, for assignment to duty. S. O. 104, c. s., A. G. O.

Shufeldt, R. W., First-Lieutenant and Assistant-Surgeon.—Relieved from duty in Department of the Platte, to proceed to Washington, D.C., and report in person to the Surgeon-General. S. O. 104, c. s., A. G. O.

Cuningham, T. A., First-Lieutenant and Assistant-Surgeon (now awaiting orders at Danville, Va.).—To report to Commanding General, Department of the South, for assignment to duty. S. O. 104, c. s., A. G. O.

Perley, H. O., First-Lieutenant and Assistant-Surgeon.—Relieved from duty in Department of Dakota, to proceed to Detroit, Mich., and report, on arrival, by letter to the Surgeon-General. S. O. 104, c. s., A. G. O.

Burton, H. G., First-Lieutenant and Assistant-Surgeon.—Relieved from duty at Fort Niagara, N.Y., and assigned to temporary duty at Fort Wadsworth, New York Harbor. S. O. 78, c. s., Department of the East.

Cochran, J. J., First-Lieutenant and Assistant-Surgeon.—Relieved from duty at Fort Lewis, Col., and assigned to duty at Fort Garland, Col. S. O. 86, c. s., Department of the Missouri.

Bushnell, G. E., First-Lieutenant and Assistant-Surgeon.—To proceed to Fort Yates, D.T., and report to the Commanding Officer of that post for duty.—S. O. 81, Department of Dakota, May 6, 1881.

Birmingham, H. P., First-Lieutenant and Assistant-Surgeon.—To proceed to Fort Riley, Kansas, and report to Major E. B. Beaumont, Fourth Cavalry, for duty with troops about to take the field in Colorado. S. O. 90, Department of the Missouri, May 7, 1881.

PHILADELPHIA, JUNE 4, 1881.

ORIGINAL COMMUNICATIONS.

ETHER DEATH: A PERSONAL EXPERIENCE IN FOUR CASES OF DEATH FROM ANÆSTHETICS.

Read before the Philadelphia County Medical Society, February 9, 1881,

BY JOHN B. ROBERTS, M.D.,

Lecturer on Anatomy and on Operative Surgery in the Philadelphia School of Anatomy.

IT has been my fortune on four occasions to witness the occurrence of death during or immediately after the production of anæsthesia. In three of these instances sulphuric ether was employed; in the other, bromide of ethyl. In none of the cases, however, was I the administrator of the anæsthetic, but merely a by-stander or an assistant in the efforts at resuscitation. On numerous other occasions I have seen patients almost die from the effects of chloroform or other anæsthetics, who were fortunately revived by well-directed treatment. These circumstances have been called to mind, many times with considerable anxiety, when resorting to anæsthesia in the performance of surgical operations; and I therefore desire to report in full the case of ether death which recently occurred under my observation. Afterwards I shall refer to the three other cases spoken of, which have been already recorded by myself or others; and finally I shall offer some remarks as to ether deaths in general.

Case I.—Death from Cardiac Failure after Etherization.

The patient, a woman, aged 26 years, was admitted to Dr. R. J. Levis's ward, in the Jefferson College Hospital, with fibrous anchylosis of the right knee and hip, occurring subsequently to arthritis, considered by her physician to be rheumatic in character. The trouble had existed about a year, and Dr. S. L. West, of Wilmington, had treated her also for chronic uterine disease, rheumatism, cardiac palpitation, and nervous prostration.

After she had been in the hospital for two days, she was placed upon the operating-table (on January 20, 1881) for the purpose of having the fibrous joint-adhesions broken up by passive motion. When she was brought into the room she was frightened and very nervous, which was attributed partly to the fact that, before she entered, a very boisterous sailor, just recovering from ether, was removed. She was asked if she had ever taken ether, and replied that she had often done so. I then, as Dr. Levis's assistant, placed my ear to the cardiac region to ascertain the condition of the heart before the resident surgeon began etherization. As I did so, she exclaimed, "I have a bad heart," referring, no doubt, to cardiac symptoms, such as palpitation, which she had experienced. Of these symptoms I had known nothing, and auscultation was begun merely as a precautionary measure. Her remark, therefore, made me listen with more care, perhaps, than I otherwise would have done. The heart's action was rapid and tumultuous, as would be expected from her excited condition, and I thought I detected an indistinct murmur. Nothing sufficient to contra-indicate anæsthesia appeared to be present.

The resident physician (Dr. York) then began to etherize slowly, using Squibb's ether poured on a couple of towels. The patient did not at first breathe very deeply, but in a short time passed into a condition of anæsthesia without the least struggling. Dr. Levis then broke up the adhesions of the hip and knee, using a mallet to loosen the patella, which was quite firmly attached to the condyles. In these manipulations I assisted, being at the foot of the bed, and, hence, away from observation of the patient's respiration and pulse.

Soon the anæsthetic was suspended, and an extension-apparatus of adhesive plaster adjusted to the limb. The time occupied in etherizing, operating, applying the plaster, and removing the patient to the ward was about half an hour (2 P.M. to 2.30 P.M.). There was no vomiting.

After the limb had been placed in position, and just before the woman was taken from the operating-table, while she appeared to be quietly sleeping, I placed my finger upon the right pulse and was astonished at its feebleness and frequency. I immediately called the resident's attention to the fact, and informed the operator of the unfavorable condition of circulation.

We all followed her bed to the ward. She had not awakened up to this time, but was unconscious, and was breathing quietly and regularly. If it had not been for the cardiac depression, nothing would have given the alarm or caused apprehension. The pulse was feeble and beating 180–200 per minute, while the regular, quiet respirations numbered about 22. As the symptoms did not improve, twenty drops of tincture of digitalis with enough whisky to fill the syringe twice (f℥j approximately) were given hypodermically at 2.35 P.M. At 2.42 P.M. an enema of about six fluidounces of whisky was administered, and twelve minutes later (2.54 P.M.) I gave a hypodermic injection of tincture of digitalis (♏x) and sulphate of atropia (gr. $\frac{1}{30}$).

Then the faradic battery, which had been brought to the bedside, was suggested as a remedial agent, but, as the respiration was continuing comparatively unaffected, it was only applied for a short time, with one pole to the neck, the other in the præcordial region. After the hypodermic of digitalis and atropia I thought the pulse became a little stronger, but this observation may have been incorrect. At any rate, in a short time the progressive cardiac failure was so patent that at 3.10 P.M. ten minims of tincture of digitalis were injected by me into the subcutaneous tissue of the breast. Ten minutes later (3.20 P.M.) atropia sulphate (gr. $\frac{1}{60}$) was injected into the mammary region, and an enema of strong hot coffee (f℥viij–x) administered.

Before these remedies were given, cyanosis of the hands was exhibited, and at about the same time respiration became somewhat irregular. The pupils were not dilated.

The patient continued to sink, and at 3.32 P.M., when respiration was almost gone, a final hypodermic injection was given, consisting of atropia, gr. $\frac{1}{60}$; tincture of digitalis, ♏x; whisky, ♏xxx. At 3.35 P.M. the patient died quietly, without having shown signs of consciousness, and, I think I am correct in saying, without voluntary motion of the limbs, from the time anæsthesia was produced.

After death an effort was made to determine the exact quantity of ether given. A new can of Squibb's ether had been opened before etherizing the previous patient, who was a powerful sailor requiring amputation of a finger, and to whom an additional quantity of the anæsthetic was given after he had partially regained consciousness, in order to insert the sutures and dress the wound. It was the noise of this boisterous patient, before he left the operating-room, that increased the alarm of the unfortunate patient who followed him. After the man and the woman had been operated upon, it was found that only six ounces avoirdupois of ether had been removed from the can. It seems fair, then, to estimate the amount taken by the woman, to whom it was not given with as free a hand, at two and a half or three ounces avoirdupois, or about three and a half fluidounces.

I may state also that the quantities of digitalis and atropia were accurately measured by the piston of the hypodermic syringe; but, as is well known, these are frequently marked incorrectly.

The autopsy was made by Dr. Morris Longstreth, the pathologist of the Hospital, twenty-one hours after death.

There was a small amount of pleural, but almost no pericardial, effusion. The heart-cavities contained fluid blood, and neither ventricle was firmly contracted. The right auricle was slightly dilated; the left thickened, and its cavity dilated, especially in the auricular appendage. The right ventricular wall was thickened and the cavity dilated, especially towards the artery. The left ventricle showed no special change. The coronary veins were filled with blood, and two spots of ecchymosis were seen on the surface of the heart. The cardiac muscle was much softened. The valves of the right side were normal, though the auriculo-ventricular orifice was dilated. The mitral leaflets were normal, with the exception of one or two patches of thickening; the orifice, however, was dilated. The aortic valves were competent, and showed no evidence of thickening, though a small fenestra was found in one leaflet. The aortic sinuses seemed pouched. The oval fossa presented an oblique opening large enough to allow the passage of an ordinary wooden lead-pencil.

Some remains of the thymus gland were visible. The lungs crepitated poorly, and were congested posteriorly; anteriorly they were pale in color. No evidence of œdema. Both lower lobes posteriorly were softened, but not granular. Section of the lung-structure showed no other conditions. The spleen presented no special change. No odor of ether was perceptible about the viscera. Left kidney was irregular, moderately firm, and deeply congested, showing, on section, no alteration of cortex, but having an adherent capsule and some subcapsular ecchymoses. The surface was but slightly granular. At several points in the pyramidal portion areas of softening from which drops of mucoid material could be pressed were seen. Right kidney was softened, and presented same condition as noted in left.

Liver had smooth surface, was moderately congested and somewhat softened. On the anterior surface of the right lobe, near the middle, was situated a non-protruding cyst, an inch in diameter, filled with dirty-brown gelatinous material. The interior of this cyst was lined with an opaque, smooth, white membrane. The ovaries showed marked cystic disease; the cyst of the left ovary was as large as a small walnut, and contained blood. A catheter was introduced into the bladder to obtain some urine for analysis, but the bladder was empty.

A marked feature of the examination was the fact that almost every organ presented some noticeable change; but in none were these alterations characteristic of any distinct disease.

Microscopic Examination. — The heart-muscle presented evidences of granular and fatty degeneration; and none of the fibres

showed normal striation. On teasing out the fibres, large numbers of oil-drops were liberated.

The appearances presented by sections of lung-tissues were very similar to those of embolism. The smaller arteries and capillaries were packed with blood-corpuscles and rendered tortuous; yet no embolus of fat or blood could be found. The lung epithelium showed no changes, but the peribronchial connective tissue was increased.

The capsule of the kidneys showed no evidence of thickening. The arteries appeared slightly enlarged and their walls thickened. The capsules of the Malpighian bodies were thicker and firmer than usual, and around them nuclear proliferation had taken place. Within the Malpighian body proliferation was likewise occurring, similar to that seen in glomerulo-nephritis. The intertubular tissue was slightly swollen, and for the most part its nuclei were more distinct and numerous than normal. The convoluted tubes were slightly irregular in outline; their basement membranes appeared unchanged; and their epithelia were swollen, markedly granular, with nuclei in most instances indistinctly visible.

The capsule of the liver was thickened, and showed active proliferation from its under surface into the interlobular connective tissue. In many of the portal canals, in the deeper portions of the organ, the connective-tissue increase was even more marked than noted above. The liver-cells appeared slightly shrunken and highly granular; their nuclei were visible, but stained poorly, and in some instances appeared almost vesicular. None of the cells showed any fatty infiltration, but on the contrary presented appearances of fatty degeneration, as evidenced by numerous small oil-globules. No changes were noticed in the interlobular vessels or ducts.

Case II.—Sudden Death after Administration of Chloral and Etherization, prior to Amputation of the Thigh.

In 1872 I witnessed a death from ether, which occurred under the following circumstances:

A man, aged 35 years, was to be subjected to amputation, for necrosis of the femur accompanied by many sinuses discharging very large amounts of pus. Twenty grains of chloral were administered immediately before the etherization, and a large amount of the anæsthetic was apparently given in a short time. In fact, the ether was pushed. Just as the amputation was to be commenced, collapse occurred and immediate death ensued.* I believe no autopsy was made. As I merely witnessed the fatal issue, I have no means of giving more accurate notes. This was at a time previous to the introduction of the elastic bandage, which was therefore of course not applied to the limb. Hence, embolism, due to forcing pus or clots into the vessels, which suggests itself, is not tenable as the cause of death.

Case III.—Death from Œdema of the Lungs after Anæsthesia by Ether.

The other case of ether death, or rather of death occurring subsequently to, but not immediately after, etherization, of which I have personal knowledge, took place in 1876. The history in brief is as follows:

A youth, aged 19 years, who had marked angular spinal curvature from caries, was admitted by Dr. T. G. Morton into the Pennsylvania Hospital for treatment of an anchylosed right knee. He was anæsthetized with two and a half or three ounces (fluid?) of ether, and subjected to tenotomy and forcible straightening of the limb. The apparatus made for the case was adjusted to the limb, and the patient, by this time conscious, was removed to his private room. He had been under the anæsthetic influence not over twenty minutes, there was no vomiting, no marked evidence of mucus collecting in the trachea or fauces, and he rapidly recovered consciousness when the ether towel was taken from his face. Fifteen minutes after removal to his room he showed alarming symptoms of asphyxia, such as cyanosis and impending cessation of respiratory motion. Dr. W. B. Hopkins and I endeavored to relieve him by depressing the tongue and dashing cold water in his face, which, however, only produced violent respiratory efforts. As the condition grew worse, and frothy, blood-stained mucus expelled from the fauces gave evidence of pulmonary engorgement, which was accompanied by labored cardiac action, we applied dry cups to the chest and drew about eight fluidounces of blood from the radial artery. Respiration and circulation seemed to improve somewhat from these measures; but he continued to sink, despite the subcutaneous injection of carbonate of ammonia and whisky, and died one and three-quarter hours after anæsthesia. Dr. Hopkins had seen that he had perfectly recovered from the anæsthetic sleep before removal from the operating-room, and even during the stage of asphxyia the patient was quite rational.†

* See Morton's Report on Ether Deaths, in American Journal of the Medical Sciences, October, 1876, p. 415.

† For a more complete account see Dr. Morton's paper in Amer. Jour. Med. Sci., October, 1876, p. 411.

The autopsy showed a deformed thorax, due to the antecedent vertebral caries, old pleural adhesions between the lung and parietes, and the lower part of the right pleural cavity obliterated by firm adhesions between the diaphragm and costal pleura. The pleural cavities showed much serum infiltrating the meshes between the adhesions; and the lungs, pitting on pressure, exuded on section large amounts of frothy fluid, as from a saturated sponge. The lung-tissue was fairly crepitant, and floated in water. The heart-cavities contained fluid blood, while the valves and muscular tissue were normal. The great vessels at the base of the heart were healthy. No foreign body was found in the trachea or large bronchi. The kidneys were not examined.

Dr. Morton considered this patient to have died from "the mucous secretion and serous effusion which invaded every available space, thus suffocating the patient." This fatal pulmonary œdema was of course due to the inhalation of ether, since the patient was in good health when subjected to operation.

The fourth death from anæsthetics which I have seen has already been reported by me,* and occurred during the administration of bromide of ethyl. A short account of the circumstances, however, may be allowable at this time.

Case IV.—Death occurring during the Use of Bromide of Ethyl as an Anæsthetic.

A boy of 18 years was received into Dr. R. J. Levis's ward of the Jefferson College Hospital for lithotomy. He was in bad condition, and the operation was therefore delayed until tonics and corroborative treatment could be employed in the endeavor to improve his general health. Finally, upon the approach of summer weather, after several weeks' stay in the ward, he was placed upon the operating-table. He was given some whisky and fifteen grains of quinine on account of his debility, and the inhalation of bromide of ethyl begun. He was exceedingly nervous and agitated before he commenced inspiring the anæsthetic, and struggled a good deal during its administration. Four fluidrachms of bromide of ethyl had been poured on the towel in divided quantities, when the cutaneous incision was made. Just then it was noticed that respiration was imperfect, and the towel was removed from his face. The lips were pinkish, and no marked cyanosis was noticed. As I was holding the lithotomy staff, I am unable to say what was the condition of the pulse; and the observation of the administrator of the anæsthetic is not recorded. A few feeble inspiratory efforts took place, but inversion of the patient, nitrite of amyl inhalation, artificial respiration, galvanism, and drawing forward the tongue were of no avail. The pinkish lips would perhaps point to death from syncope, but the respiratory symptoms were the first to attract attention. It may be that the pulse failed a moment previously. The autopsy showed a slight odor of the bromide of ethyl emanating from the thoracic and abdominal cavities; old pleuritic adhesions; areas of consolidated lung, containing cavities, due to catarrhal pneumonia; some dilatation of the heart, and kidney changes. The microscope showed the beginning of renal inflammation, and discovered such atrophic alterations of the heart-fibres as are often present in connection with advanced lung disease; but there was no fatty degeneration of the cardiac muscle.

Such, then, are the clinical features of the four cases of death from anæsthesia which I have witnessed. Though the pathological features of these cases and the physiological actions of ether and other anæsthetic agents could be much better discussed by other members of the Society than myself, I desire to make some general remarks on the subject of ether death. First, as to the case that forms the text of my paper. Was she a proper subject for etherization? was the anæsthetic given properly? was the after-treatment properly conducted? how did ether kill her? are questions that we must study thoughtfully, and which I offer for thorough discussion and criticism by the members of this Society.

Was she a proper subject for etherization? The patient's heart was ausculted immediately previous to the administration, and nothing found to contra-indicate ether. Indeed, even if marked organic disease be detected in patients about to be anæsthetized, it is not regarded as an absolute bar to the administration. Ether is frequently given to such patients, and J. W. Haward, in advocating the superiority of ether to chloroform, states that he has given chloroform to persons with extensive heart disease.† Kappeler and Reeve reject‡ the idea that fatty degeneration of the heart is an important factor in chloroform deaths; and it would be expected to be a much less important factor in ether death. Hence, even if valvular disease or fatty degeneration had been discovered, it would not have precluded the administration. Dila-

tation of the heart is probably a more dangerous condition than any other when anæsthetics are to be administered. The woman had been etherized twice previously, and, according to her husband, by a much larger amount of ether than given on the fatal occasion. Her physician, Dr. S. L. West, tells me that he etherized her on the last occasion, which was fifteen months ago, without any unpleasant effects; but I am not sure that this was previous to her rheumatic attacks. Since her death he has written to me that she had shown cardiac and renal symptoms while under his care, but that he had examined the urine twice without discovering albumen or sugar. As we had auscultated her heart and found no special lesion, as her physician had discovered no albuminuria, and as she had taken ether twice previously without trouble, she *was* a proper case for etherization. It was negligent, however, in us at the time of operation not to inquire into the condition of the kidneys; for then we did not know of Dr. West's negative analysis. Hundreds of patients are etherized every year without a urinary analysis being made; among whom some certainly have Bright's disease. Although the discovery of albuminuria would not have deterred us, as the operation could not have been performed without it, still, as it is well known that renal disease prevents the ready elimination of the anæsthetic, every surgeon should take the preliminary precaution of examining the urine at least in cases of chronic disease.

Was the ether properly given? The amount used was small, it was given, sprinkled upon two towels, by a resident who was accustomed to using ether, it was of Squibb's manufacture, and produced during the inhalation nothing to attract the administrator's attention. Hence it may be assumed that this question can be answered affirmatively.

It seems, indeed, that ether could hardly have been administered to any patient and under any circumstances better calculated to dispel anxiety. There was no special heart-lesion observed, there had been no albuminuria, there was no cutting operation to cause shock, the quantity of ether was small and of the best quality. Yet she died.

Was the treatment of the patient after dangerous symptoms occurred conducted properly? I think we may say that it was. The only indication of danger observed was the rapid and feeble pulse; the respiration was not bad, and the unconsciousness appeared to be merely such as is often seen after full anæsthesia. In fact, one gentleman remarked that she merely seemed to be sleeping off the anæsthetic. The indication for treatment then seemed to be cardiac stimulation, which was attempted by digitalis and whisky. The main reliance was upon the former, for the enema of whisky (f℥vj), though comparatively large, would not be absorbed very rapidly; and the spirit given hypodermically was in small amounts and at considerable intervals. It is well known that belladonna is claimed as advantageous in shock and in respiratory failure: hence the atropia given was not inappropriate, although respiration was good and not irregular until near the fatal termination. Morphia was suggested, but the comatose condition of the patient seemed to me to contra-indicate its use. Nitrite of amyl and the battery, which was indeed used for a short time, were, I believe, appropriately rejected. Is it possible that hot-air baths would be available in such conditions by causing cutaneous elimination of the anæsthetic? I know nothing clinically on this point, which I merely throw out as a suggestion.

How did ether produce death in this instance? The recent report to the Scientific Grants Committee of the British Medical Association* states that the chief dangers in anæsthesia are—1, sudden stoppage of the heart; 2, reduction of blood-pressure; 3, alteration of the pulse-respiration ratio; and, 4, sudden cessation of respiration. The danger from ether, it is said by the same report, approaches from the pulmonary rather than from the cardiac side. I believe that, as a rule, danger from ether is shown by the respiration, and I always in etherizing have watched the respiration with more care than the pulse; but this custom, which is general among surgeons, I now feel is founded upon error. The patient whose case I am studying did not present any special respiratory symptoms until more than a half-hour had elapsed from the time that the circulatory symptoms presaged imminent death. She was evidently dying long before respiration showed any sign of her danger. The

* British Medical Journal, December 18, 1880, p. 971.

pulse-respiration ratio was greatly altered, for with a feeble pulse beating 180–200 per minute the respirations were very little above normal. It was this rapid feeble pulse that struck me with astonishment, when every other clinical appearance seemed to indicate safety.

We have become too much inclined to look upon ether as having no depressing effect on the heart. If we examine clinical evidence and that deduced from experiment, we shall find that ether does at times depress the heart, but much less actively than chloroform. The Committee of the Royal Medical and Chirurgical Society stated in 1864 that ether exerts but a very slight depressing influence on the force of the heart's action.* This authoritative statement of the slightly depressant effect of ether on the heart, which has been reaffirmed and repeatedly proved, has led us to look upon it as almost an impossible thing for ether death to occur from cardiac failure. Many readers perhaps have neglected to continue the perusal of the above report to the modified statement that "ether destroys life partly by enfeebling the action of the heart, but chiefly by arresting the movements of respiration."†

Kappeler says it is by no means apparent that ether death in human beings always begins by disturbance of respiration and proceeds from the respiratory system.‡ Dr. J. C. Reeve believes it to be an error to think that there is a difference in regard to the actions of chloroform and of ether upon the nervous centres of respiration and circulation,§ and says that Kappeler reports three instances of sudden cardiac death from ether. In speaking of the comparative safety of ether, ethidene dichloride, and chloroform, the report to the British Medical Association asserts that the circulation is more readily established when its cessation is due to ether, than to the two other anæsthetic agents ;‖ which statement infers that ether may produce dangerous cardiac depression.

This evidence all tends to show that surgeons lay too much stress on the respiratory action of ether, and perhaps administer it carelessly because they feel that respiration is easily watched during anæsthesia, and that artificial respiration can immediately be instituted. Some writers have attributed perfect safety to ether, and have even gone so far as to state that if complicated instruments are avoided and nothing but the towel and sponge used there is absolutely no danger.¶

All this is wrong. Every man should feel that anæsthesia, which places many of the animal functions in abeyance, is akin to death, which is merely the additional obliteration of circulation and respiration. All anæsthesia is dangerous, though the degree varies with the agent.

There is certainly no doubt that death in the instance before us was due to ether given to a patient not specially obnoxious to the agent, and given in the usual manner ; and that death resulted directly from cardiac depression without respiratory symptoms.

In glancing over the four cases presented for your consideration, I may make the following summary. The woman (Case I.), whose death I have been discussing, certainly died because of the influence of ether upon the heart ; the man (Case II.), whose sudden collapse occurred after the ether had been pushed, possibly succumbed to its cardiac depression also, though the notes are not sufficient for an accurate determination ; the young man's death (Case III.) was due to œdema of the lungs resulting secondarily from etherization ; while the bromide of ethyl case (Case IV.) presents a history pointing to cardiac paralysis as the cause of the fatal issue. In the first two and the last case death was primary, because the patients never awoke from the anæsthetic sleep ; in the third it was secondary, because the asphyxia due to pulmonary œdema supervened after consciousness had returned.

How are ether deaths to be avoided ? This is, after all, the question of paramount importance, that forces itself upon every one. It has been suggested by Dawson of Leeds** that the fatal effects of ether are due to the pulmonary circulation being impeded by capillary contraction caused by the cold produced by the ether. Then embarrassment of the right heart occurs because of the unusual resistance it has to

overcome. These and other theories belong to physiology rather than to clinical surgery; and I shall not stop to discuss them. It would seem that death from ether anæsthesia may occur at times when there is no reason in the patient, or in the method of administration, to expect such a result. It is imperative upon us all, however, to take every precaution to avoid such an occurrence; and yet I am convinced that no powerful drugs are administered as carelessly, as recklessly, and by as incompetant hands as anæsthetics. Let every one remember that an anæsthetized patient is really a patient with one foot in the grave, and he will feel the responsibility that rests upon him when he gives an anæsthetic. Lungs, heart, and urine should always be examined before the administration, for, though lesions here should not preclude anæsthesia when necessary, the knowledge of such lesions would enforce caution and care. I have seen persons profoundly anæsthetized without the least examination or inquiry having been made as to these organs. I have seen them left by the physician before they had regained perfect consciousness. I have seen ether given by persons who knew nothing of its dangers or the methods of averting evil results. Every member of this Society, including myself, has probably been guilty of these things; and yet we are astonished when a patient dies from ether. The wonder really is that ether deaths are not more frequent than they are.

Anæsthesia is partial death, and one step further is death. Hence the man intrusted with the ether towel at an operation should be the most skilful of all the assistants. In many instances more skill is required in the administration of the anæsthetic than in the performance of the operation. Yet this duty is generally relegated in hospitals to the junior residents, and in private practice often to the nurse or a layman. It would be useless and improper for me to attempt to instruct this body in the method of giving anæsthetics, for you all have given them frequently. The only point I desire to enforce upon your attention is, "Take care. All anæsthesia is dangerous." Ether anæsthesia is less so than chloroform anæsthesia; and hence I believe, as I have elsewhere written,* that chloroform should be rejected entirely as an anæsthetic in practical surgery. If anything safer than ether is found, we must reject ether.

Anæsthesia is undoubtedly essential in surgery, medicine, and midwifery, and is properly resorted to in cases of cardiac, pulmonary, and renal disease when necessity demands it. In many cases the risk without it would be greater than the risk with it; but it should be regarded as a powerful agent for evil as for good. Unfortunately, we have, as yet, no infallible means of predetermining which cases will be instances of death from anæsthesia.

A report of all the ether deaths that have occurred in the last few years would be a valuable aid in studying the fatal action of the agent, and I have therefore appended to this paper a list of those that I have found recorded since January, 1872.

In the *British Medical Journal* for March 2, 1878, pp. 290, 291, Mr. Cawtley Dawson gives the histories of eighteen cases of so-called deaths from ether, occurring during the years 1873, '74, '75, '76, '77. In this list, however, he records some cases which should not properly be claimed as deaths from ether. He eliminates nine, and accepts the remaining nine cases, in which he thinks ether was the cause of death. Of these he gives a tabulated statement. Among the number rejected by him is the case reported by me (Case III.) as a death from œdema of the lungs after ether. He also rejects the case marked No. 14 in his list, for a similar reason,—namely, that death was caused by previous pulmonary trouble aggravated by ether. These should certainly be regarded as deaths resulting from etherization. His case No. 13 was that of a patient in whom cerebral hemorrhage was found after death. This appears from the short account to have been caused by the etherization, and should not be rejected. These three cases, added to the nine which he accepts, would make twelve instances of ether death; but I reject his accepted case No. 16, because chloroform was mixed with the ether, and the woman died one minute after the beginning of inhalation, possibly from the small amount of chloroform in the mixture.

Hence I have from him eleven cases of primary and secondary ether death, of which No. 1 is Case III. of my present paper. To these the two other ether cases in this paper may be added, making thirteen cases in all.

Continuing my search, I have found reported during 1878, 1879, 1880, seven other cases.

I. *British Medical Journal*, May 18, 1878, p. 730. Man, aged 50 years; strangulated hernia for four days; London Hospital. Ether,

* Transactions of the Medical Society of the State of Pennsylvania, 1880, pp. 152, 153.

1½ ounce, given for examination of hernia; respiration ceased, and pulse beat for one and a half minutes afterwards. Left ventricle contracted; heart apparently healthy; lungs extremely congested; kidneys slightly granular, but not congested; commencing peritonitis.

II. Turnbull's *Artificial Anæsthesia*, 2d ed., p. 47. Mr. G. W. Callender, surgeon to St. Bartholomew's Hospital, London, told author of a case occurring in that hospital before his visit to America. Patient was admitted for intestinal trouble. This may be the same case as No. III. below.

III. *London Lancet*, Am. ed., Nov. 1880, p. 420. Reported by R. N. Hartley; operator, Mr. Teale. Man, aged 66 years; intestinal obstruction; ether by Clover's small inhaler, a little over one ounce. After fifteen minutes, while surgeon was operating for colotomy, the man vomited, took a deep inspiration, then appeared about to vomit again, but sank on pillow and died; pulse was good when he first vomited. This seems to be a death from interference with respiratory action.

This may be the same case as that mentioned above by Turnbull.

IV. *British Med. Jour.*, April 12, 1879, p. 562. Girl, 8 years; strabismus; Moorfields Royal Ophthalmic Hospital. Ether and a little chloroform; discharged two or three hours after operation, and removed to home by mother; died collapsed about seven hours after operation. No autopsy given. Not established as a true ether death.

V. *British Med. Jour.*, February 7, 1880, p. 215; from *Boston Med. and Surg. Jour.* for January, 1880. Man, 55 years; hip-injury; ether for diagnosis; in Providence; respiration stopped after fifteen minutes of inhalation. Serum beneath arachnoid, valvular disease of heart, cystic degeneration of kidneys.

VI. *British Med. Jour.*, February 7, 1880, p. 215; from *Canada Lancet*. Lady; extraction of teeth; scarcely one ounce used; death from paralysis of the heart.

VII. *Cincinnati Lancet and Clinic*, October 30, 1880, p. 380. Dr. N. P. Dandridge's case. Woman, 43 years; necrosis of femur; had been etherized twice, only a short time before, for same disease in same hospital; operation begun, when it was noticed that there was no respiratory motion and no pulse; reacted slightly, but died in about two and a half hours. Lungs healthy, except a few emphysematous blebs; heart-muscle and valves apparently normal; kidneys showed no structural change, but were anæmic.

Of these seven cases, Nos. II. and III. are probably the same, and No. IV. is not a pure ether death, because chloroform was also given: hence we have really but five cases properly attributed to ether. These five, added to the thirteen cases mentioned previously, give eighteen cases of death, fairly attributed to the effects of ether, that have occurred between the years 1873 and 1880 inclusive.

Kappeler, in his article on Anæsthetics in Billroth and Luecke's "German Surgery,"* gives thirteen fatal cases occurring subsequent to 1872;† but I am unable at present to refer to the original work, and cannot compare the cases with Dawson's and my own list.

In *British Med. Jour.*, December 18, 1880, p. 997, Mr. Burton and Dr. Jacob give eleven cases of death occurring during and after administration of ether in Great Britain and Ireland from 1870 to 1880. These correspond in many instances, of course, with Dawson's list.

ETHYLENE BICHLORIDE AS AN ANÆSTHETIC AGENT; WITH A CONSIDERATION OF ETHYLENE METHYLETHYLATE, ETHYLENE ETHYLATE, ETHYL NITRATE, AND ETHYLIDENE BICHLORIDE.

BY EDWARD T. REICHERT, M.D.

(Continued from page 522.)

THE Effect on the Arterial Pressure.—When the ethylene is given by inhalation and by the modes already described, the arterial tension is but little affected during the first few minutes, unless the vapor be given in a very concentrated condition (Exp. X., XII., and XIII.), and then there is a very rapid decline, equalling nearly one-third of the normal, which is followed by a rise of half this amount, and then by a subsequent fall. In experiments where the air was heavily laden with the vapor (Exp. XIII.) essentially the same result occurred, but in the others, where the vapor was given more diluted, the fall of pressure is not nearly so marked, and the subsequent rise may nearly reach or even go above the normal. In Exp. XI., XII., and XIII. the animals were curarized to obviate any complications of the respirations, and the artificial respiratory apparatus, of course, employed. In Exp. X. the cone was kept almost saturated with the ethylene, and in Exp. XII. and XIII. sponges were placed in the bottom of the bottle, which were kept continually moistened with the liquid, and the air being driven through them, thus necessitating the absorption of considerable of the anæsthetic by the current of air.

From these results it will be seen that the most pronounced effect of the ethylene on the blood-pressure when given by continuous inhalation, whether in a dilute or concentrated form, is to produce a diminution to zero, but which is transiently interrupted by a rise towards the normal, which is various in extent and may go even above it (Exp. XII.). As these changes in the pressure occur in curarized animals, any effect which altered respirations or muscular movements might have is obviated by this toxic condition; but as this diminution of pressure is accompanied by a frequent pulse and diminished pulse-curves, which latter has already been pointed out to be due to a depressed condition of the cardiac power, it is at once indicated that the fall of pressure is cardiac in its origin. However, several experiments made on animals with cut pneumogastrics gave results identical with those already recorded on normal animals. It therefore remained but to show whether the heart or vaso-motor system (or both) was the cause of the above results. Consequently, the heart being the most probable agency, experiments were made on animals in which the pneumogastric nerves and the cervical spinal cord were cut, which would necessarily sever all nervous connection with the heart, and whatever results would then follow would evidently be due to a direct cardiac action or to one on the peripheral vaso-motor mechanism.

Exp. XIV.—Rabbit.

The fall of pressure still occurring, the following experiment was made to determine if the vaso-motor peripheries were concerned, and, in order to accomplish this object, the pneumogastric nerves and cervical spinal cord were severed and the

thoracic aorta ligated, this latter operation cutting off communication of the blood with the major part of the vascular capillaries, and practically (for our purposes) annihilating the vaso-motor peripheries, while the section of the cord practically destroys the vaso-motor centres.

The fall of pressure being still as marked in this last experiment, it must be concluded that the depression of the cardiac power is the cause of it, and, in further corroboration of this, it has been found that in animals whose thoracic cavity was opened the direct application of the ethylene to the heart caused its slowing or immediate arrest, and, further, that in animals slowly poisoned an autopsy revealed the heart arrested in diastole. It is probable, though, that the transient rise of pressure which interrupts the fall in normal animals is vaso-motor and both centric and peripheral in its origin, because it did not occur in either of the last two experiments; yet it was well marked in an experiment made on an animal with a cut cervical cord which has not been recorded in this paper.

In looking over the above series of experiments it is interesting to note that, although the drug is a direct and decided cardiac depressant, this organ is capable of bearing a considerable amount of depression before its complete paralysis, and, as was stated early in the paper, the respirations are always the first to succumb, and death is caused in this way. And it was further found that if after the complete cessation of the respirations the artificial respiration-apparatus was attached and air laden with the ethylene vapor driven into the lungs the heart would still continue to pulsate for some minutes. After the blood-pressure had fallen almost to zero and the heart-beats could no longer be traced on the drum, yet when the thorax was opened the organ was still feebly pulsating, and continued so for several minutes. This fact is certainly an interesting one to remember, for in case of accident during its use the absence of pulsations at the wrist would not be so serious as it otherwise would, and by reference to the text immediately following Exp. IV. the invaluable services to be expected from the amyl nitrite cannot be overestimated. And in those cases where a sudden arrest of the respiratory movements occurs, the same good services can be expected, for it is evident, from the results of some of the preceding experiments, that the ethylene acts primarily as an excitant and secondarily as a depressant to the respiratory centres. That the respiratory movements must be arrested by centric paralysis is evident from the results of the experiment just quoted, for if it were due to a paralysis of the respiratory muscles, or of the nervous communication failing to convey the impulses from the centres, scarcely such a rapid recovery of full, regular, almost normal respirations could occur, since the nitrite acts as a depressant to both the motor portions of the cord and nerves and voluntary muscles. Yet the recovered respirations could be attributed to some extent, probably, to a greater supply of blood to the anæmic respiratory centres, for the reason that the increased force and frequency of the heart must have been the cause of driving considerably more blood through the centres, even if the blood-pressure was not increased and the respiratory centres were thus also indirectly stimulated by the nitrite. It is very evident that in the nitrites we have both respiratory and cardiac stimulants, and therefore a double physiological antidote, by acting similarly upon the depressed heart and respiratory centres; and the importance of this knowledge cannot be too deeply impressed on the minds of those who will hereafter make use of this preparation.

As an anæsthetic for general surgical use it is undoubtedly superior to any yet introduced, with the exception of its isomeric compound ethylidene chloride and ether, and is inferior to the latter in but the single point regarding the relative degree of safety; and, while it in all probability is equal to chloroform in strength, promptness, and permanency of effects, it is fully as much superior to it in the point of safety as it is inferior to ether. This last is very evident by referring to the records of the experiments made on the arterial pressure, where it will be seen that the diminution of the arterial tension is that of a gradual decline, decidedly unlike that caused by the slow administration of chloroform, because of the absence of those wide and remarkable variations which occur, especially before complete anæsthetization. Also, when the vapor is given in a state of concentration by saturating a muslin cone with the liquid and placing it directly over the tracheal tube, as in Exp. X., although we have a decided fall of pressure, yet it does not immediately decline to zero, but consumes twenty-seven minutes in reaching within as many millimetres of it. Now let us turn to a similar experiment made with chloroform, and the difference in the results is strikingly great:

Exp. XVI.—Rabbit.

Time. M. Sec.	Pressure. Mm.	Remarks.
1.	59	
		Gave thirty minims of chloroform by inhalation from a muslin cone held over the tracheal tube.
.10	58	
.20	57	
.30	52	
.45	48	
.50	34	
2.00	18	
.10	12	No pulse.

The diverse and interesting results of these parallel experiments are so valuable as scarcely to be overestimated in a comparison of the relative safety of the two compounds, as the pulse in the ethylene experiment could be detected on the tracing for over twenty-five minutes, notwithstanding that the animal was continuously inhaling the vapor during the whole of this time, while in the chloroform experiment but a single dose was placed on the inhaler, the pulse-curves rapidly diminished in size, and the pressure fell to twelve millimetres in a little over two minutes, and the pulse was extinct.

It needs no further argument to prove that this article (or, probably, ethydene chloride) should replace chloroform in such cases where ether cannot be used; but, as it is inflammable, care must be exercised in its use at night, and, as it is a cardiac and respiratory depressant (in toxic amounts), the same cautions should be observed in its use, and never should it be employed, if possible, without amyl nitrite at hand.

Before concluding, I take pleasure in expressing my indebtedness to Mr. Edward Hance (of the firm of Hance Brothers & White, manufacturing chemists, Philadelphia) for the presentation of this valuable ether for the purpose to which it was devoted. It is almost unnecessary to state that particular care was exercised in the manufacture of this specimen to have it pure.

Ethylene Ethylate and *Ethylene Methylethylate* were experimented with, and, although each of them possessed some slight anæsthetic powers, they were so feeble in this respect and caused such distress in breathing that they were abandoned as useless.

Ethyl Nitrate was used by Simpson,* who found it easy and pleasant to inhale, and to possess very rapid and powerful anæsthetic properties, and that small quantities, such as fifty or sixty drops, sprinkled on a handkerchief produced insensibility after a few inspirations. Shortly after, Nunnelly† stated that it possessed not much, if any, anæsthetic power; and my own experiments confirm this, as the following result will show:

"*Rabbit.*—Time, 12.32. Added one drachm to inhaler; .32½, struggles; .33, breathing deeper and slightly faster; .34, no change; .35, added a second drachm to inhaler; .35½, respirations again temporarily increased; .37½, orbital reflexes slightly diminished (?); .39, added a third drachm to inhaler; .40, respirations increased; .43, animal not anæsthetized, but somewhat drowsy, and, although the inhalation was continued for several minutes, no anæsthesia was produced."

Ethidene Dichloride, Ethylidene Dichloride, or *Ethylidene Bichloride* ($C_2H_4Cl_2$),

* Edinburgh Medical Journal, 1848, p. 741.
† Proceedings of the Provincial Medical and Surgical Association, 1849.

which is isomeric with the ethylene bichloride, has of late attracted attention through the researches of the British Anæsthetic Committee,* who found that the exposed heart of the frog, in a glass jar containing an atmosphere impregnated with this vapor, continued beating slowly and regularly throughout the experiment, which lasted, in several cases, for twenty and twenty-six minutes respectively, although the animals were anæsthetized in from four to five minutes. In rabbits in which the thorax was opened and artificial respiration maintained, the cardiac contractions continued vigorous throughout the observations, which continued, in one instance, for forty minutes. Dogs were anæsthetized in from two to three minutes, and were kept fully anæsthetized for half an hour without the slightest failure of the respiration or heart. In experiments with the thorax opened and heart exposed (artificial respiration being kept up) no failure of the heart's action was observed, although the air passing into the lungs was saturated with the vapor. They further state that, practically, the animal can live for a prolonged period in a state of complete anæsthesia under the influence of the ethidene dichloride, while it dies in a short time under chloroform. And in six cases in which it was used† they concluded that no injurious effects on the respiratory mechanism occur; that the pulse is lowered in frequency, but increased in volume, and in the deepest anæsthesia it was steady, regular, full, and compressible; that no failure of cardiac action was present, as they were led to anticipate in their experiments on animals; that there was never blueness of the lips or pallor of the countenance; and, lastly, that the anæsthetic "*presents all the advantages of ether without any of its disadvantages.*" In a more recent contribution‡ it is asserted that the *arterial pressure gradually but slowly fell*, and under repeated doses reached a minimum of twenty millimetres, and after prolonged and constant use was gradually brought down to seven millimetres.

Binz§ used it in six experiments on man, and to his satisfaction, and found that when the patients were fully anæsthetized the breathing became spasmodic and shallow, the pulse lowered, but fuller and more compressible, and all of them presented the appearance of a strong cardiac stimulant. In two cases there was a rise in the pulse-rate, followed by a fall, and in a third case the pulse fell from ninety to eighty. The doses used varied from a drachm to a drachm and a half. More recently Reeve‖ has experimented with it, and his results "show a diminution of arterial pressure, not as occurs when chloroform is used, but, unlike it, it does not advance to complete extinction, nor are there such wide variations in effects at different times in the same animal as in the case of chloroform. . . . Snow believes that it will not be liable to cause sudden death, as chloroform sometimes does. In sixteen cases it did not cause nausea or vomiting, although food had recently been taken in several of them." Steffen¶ reiterates Snow's belief.

In making the above quotations the writer's object is threefold: first, to give sufficient detail, so that a just comparison can be made with the action of its sister compound, the ethylene bichloride, which the British committee stated to cause severe convulsions and no anæsthesia up to that time, while the ethidene dichloride promised to be "an excellent anæsthetic;" second, to call attention to the fact that it does cause a decided lowering of the arterial pressure, and, therefore, cannot "possess all the advantages of ether;" third, that a death has already resulted from its use.** It is probable that, while this anæsthetic is undoubtedly safer than chloroform and certainly more dangerous than ether, it bears a position of relative safety and power similar to that of its sister compound, the ethylene bichloride.

SPINA BIFIDA CURED BY INJECTION OF IODO-GLYCERIN SOLUTION.—Mr. Berry (*Brit. Med. Jour.*, vol. i., 1881, p. 468) reports one success, one partial success, and one failure. His failure was due to allowing the partial escape of the spinal fluid. He advises sealing up the wound made by the trocar at once with collodion.

NOTES OF HOSPITAL PRACTICE.

PENNSYLVANIA HOSPITAL.

OUT-PATIENT DEPARTMENT.

SERVICE OF DR. CHARLES T. HUNTER.

Reported by JOHN GILLESPIE, JR., M.D.

WOUNDS OF THE HAND.

THERE is no class of injuries and no part of the body which exhibit so promptly the good effects of *rest*, as wounds of the hand. Superficial wounds of the hand, if of slight extent, do not require the application of a splint, but in the treatment of all wounds which extend below the deep palmar fascia the hand should at once be put at *rest*. Very often patients come to this dispensary with hands which are in a shocking condition, as the result of neglect of this procedure. Punctured wounds are especially prompt to respond to this treatment. There have been cases in which an apparently very slight wound has been followed by very diffuse inflammation, even extending along the tendons of the forearm, requiring months of constant attention, while in other cases of exactly similar description, in which the hand has been placed at *rest*, the wounds have healed in less than a week's time. On account of the loose cellular tissue of the hand, neglected injuries of it are apt to be followed by profuse suppuration, while, on the contrary, its vascularity will promote the rapid healing of wounds which are properly managed.

Dr. Hunter, in his address on Surgery,* alluding to the comparative vascularity of the hand and scalp, asserts that the hand is as richly supplied with blood-vessels as the scalp, and claims that the rapid healing of wounds of the head and face is not due to any superiority of vascularity, but to the fact that the arrangement of the muscles of the scalp and face permits absolute rest without any difficulty, while the hand, with its numerous joints and tendons, cannot be so easily controlled; and in the same paper he says that he has never known an instance in which a deep wound, either of the hand or of the foot, has united by first intention, except when the wounded member was put at absolute *rest*.

The closure of wounds of the hand may, in the majority of cases, be secured without the use of sutures, the position of the hand and the use of properly-applied strips of adhesive plaster being fully sufficient to accomplish the purpose, avoiding, at the same time, the irritation caused by the sutures. It may safely be said that where there is the least possible degree of laceration or contusion of the sides of the wound, sutures should not be used.

The position of the hand which is best adapted to secure the rapid union of wounds is the semi-flexed, as by this means the contraction of both the flexor and extensor muscles is avoided. To secure this position, the splint, which is to be well padded, should have a wad of oakum or other soft material placed upon it in such a position as to allow the hand to partially grasp the wad. Abscess of the hand when beneath the deep fascia is also favorably influenced by *rest*. The mistake is sometimes made of removing the splint before the divided tissues have formed a sufficiently firm union to enable them to endure the slightest strain. The hand should be retained upon the splint until granulation has well advanced and all local inflammation has disappeared. Care should be taken to avoid anchylosis of the joints by making motion of the fingers at each change of dressing.

The present spring has been an unusually favorable season for demonstrating the value of *rest*, for, although all wounds in which there was the slightest amount of laceration did badly, those wounds which were not treated by absolute rest were remarkable for the extensive suppuration attending them.

There have been a number of very interesting cases of wounds of the hand treated at this dispensary during the past two months, but for illustration of the value of *rest* a few cases will suffice.

Case I. Punctured wound from a pair of scissors being pushed into the palm of the hand.—The woman applied for treatment three days after the infliction of the injury, her hand being at that time much swollen, inflamed, and very painful. The wound was dressed with laudanum and water, and a palmar splint applied. On her return the next day the swelling had almost entirely disappeared, and the hand was free from pain. The improvement steadily continued, and on the fifth day the splint was removed and the woman was discharged, cured, two days afterwards.

Case II. Punctured wound of hand from the handle of a paint-brush.—The patient

* Transactions Medical Society of Pennsylvania, 1879.

applied for treatment the next day after he was hurt. The wound was inflamed, the edges red and pouting, and widely separated.

On account of the protest of the patient, he was allowed to go (after being warned of the consequences) without a splint, a laudanum-and-water dressing only being used. He returned, however, the next day with his hand greatly swollen, the tissues around the wound indurated and exquisitely sensitive. A palmar splint, with the same dressing as before, was applied. The next morning the patient bore voluntary testimony to the almost instant relief of pain he had experienced, and the swelling had so much subsided as to loosen the bandage, and in less than a week the wound had entirely healed.

Case III. Lacerated wound caused by thrusting the hand through a pane of glass.—Two days after receiving the wound, which was about one and one-half inches long, the woman applied for treatment, the hand being in very much the same condition as in the previous cases. The edges of the wound were brought into apposition by means of strips of adhesive plaster, carbolized water dressing applied, and the hand placed upon a splint.

Upon the tenth day after the accident the splint was removed, the wound being very nearly healed.

Case IV. Incised wound.—For two weeks after the accident the woman was treated by a surgeon outside, but the wound continued to grow more painful and the hand more inflamed each day. Upon application at the dispensary her hand was placed upon a splint, and in five days all appearance of inflammatory action had disappeared, and the splint was removed, the wound being entirely healed.

Case V. Compound dislocation of index finger, with contused wounds of the hand, by being caught between the buffers of railroad-cars.—For five days the wounds were treated at home by the boy's friends, and when he came for treatment the inflammation had extended up the forearm, the contused tissues of the hand were sloughing out, and the entire hand was infiltrated with pus, requiring repeated lancing to accomplish its evacuation.

The dislocation was reduced, poultices applied, and the hand placed upon a splint.

After the formation of several abscesses, in seven weeks the wounds had almost healed, requiring nothing but a simple unguent dressing.

Case VI. Incised wounds of back of hand, just below the wrist.—Sutures and straps were used to close the wounds, and laudanum-and-water dressing used, and the hand placed upon a splint. In three weeks the wounds had apparently healed and the splint was removed. The next day the hand and forearm were red, swollen, and painful, in consequence of which the splint was reapplied, and in twenty-four hours the swelling had greatly diminished. Two weeks after this the splint was again left off, and the same sequelæ ensued, necessitating recourse to the splint again. Finally, six weeks after the injuries were received, the splint was omitted, without ill effects following.

This patient was old, and addicted to the use of alcohol, which circumstances account for the slow healing of the wounds.

Case VII. Incised wound of back of hand, the extensor tendon of the index finger being severed.—The ends of the tendon were brought together with a silk thread, laudanum-and-water dressing applied, and the hand placed upon a splint. On the seventeenth day the silk suture came away, and after this the wound rapidly healed, the motion of the finger being perfect. There is no doubt that if the soluble catgut thread had been used, the same result would have been obtained much more quickly, as the irritation caused by the silk suture prevented the wound from closing.

This is the second case of tendon suturing of which I have known; both were successful; and the success could not have been obtained except by strict observance of *absolute rest.* No matter what dressing may be used, in deep wounds of the hand, union will not take place so readily without immobilization of the wounded part as it will without any dressing, if rest is enforced by means of a splint.

INOCULATION WITH HYDROPHOBIC AND OTHER SALIVA.—Pasteur seems to be getting into the bad habit of hasty generalization. A little while ago he announced that he had found a new *microbe* in the blood of some rabbits killed by inoculation with the blood of a hydrophobic child. He then thought he had laid his finger on the specific virus of hydrophobia; but he now announces that in some experiments performed with the saliva of children dying of broncho-pneumonia he had produced precisely the same results.

TRANSLATIONS.

DIFFERENTIAL DIAGNOSIS BETWEEN SCARLATINA- AND OPIUM-ERUPTION.—Bernouilli (*Correspondenzblatt für Schweizer Aerzte; Deutsch. Med. Wochens.*, 1881, p. 161) gives the following:

Scarlatina.	*Medicinal Eruption.*
History of contagion.	No history of contagion; occasionally history of previous attacks of the same kind.
The eruption finely punctate; only later is it confluent. Beginning on the neck, reaches its maximum in one to two days. Occasionally severe burning and itching; often chills. It may be accompanied by urticaria and pustular lesions. Duration one-half to one week. Desquamation occurs after a longer or shorter period, the scales branny or lamellar.	The eruption is diffuse, not punctate, or, if punctate, the punctæ are not divided by healthy skin, but are situated on an erythematous surface. The eruption begins on the neck, and reaches its maximum in one to two days. The lower half of the extremities often remains free. There is always itching and burning. Frequently chills. Urticaria and erythema papulatum are often associated with it. Duration four to eight days. Desquamation after some five days, branny or lamellar.
The tongue at first thickly coated, later smooth and red. Angina, with or without diphtheritis. Gums inflamed. Blood or albumen in the urine.	Tongue and gums normal. The medicine generally to be found in the urine.
Temperature continuously high.	Temperature (often with chills) very high, course normal, or sub-febrile.
Pulse usually frequent.	Pulse moderately increased or normal.
Localizations in the organs of hearing, joints, and kidneys.	Slight eczema often occurs as a sequel.
Relapses are rare; pseudo-relapses are mostly like measles. Rarely complicated by other diseases as sequelæ.	Relapses under the same circumstances almost invariable, the course of symptoms being about the same each time.

NEW METHOD OF TREATMENT IN VAGINITIS. — Dr. Terrillon (*Bull. Gén. de Thérap.*, 1881, p. 193), dissatisfied with the usual remedies employed in contagious vaginitis, has devised a sort of ointment to be injected by means of an instrument which appears, from the description given of it, to be a combination of a speculum and a syringe. It consists of a reservoir terminating in a tube four or five inches long, with a bevelled opening. The reservoir is covered by a hinged cap, through the top of which runs a rod attached to a piston fitted to and intended to play in the reservoir. The latter being charged with the ointment, and the terminal tube being introduced into the vagina, the piston is pressed down upon the ointment contained in the reservoir, forcing it along the tube and discharging it in the form of a plug about one-third of an inch in diameter at the opening, which may be placed at any point in the vagina up to the os uteri. A small portion of ointment being deposited at the desired point, the tube is withdrawn, and the ointment slowly melts in the upper part of the vagina and finds its way down, enduing every part of its surface with the contained medicinal agent. The advantages of this form of medication are that it can conveniently and almost painlessly be applied in small vaginas, such as those of recently-deflowered girls, who are most frequently the subjects of acute vaginitis, and that its action is slow and constant. Except in very roomy vaginas, the ointment is retained without a tampon; and experiment has shown that a certain quantity of it can be found in the vagina so long as eight to ten days after its introduction. In spite of this persistence, the ointment does not form an irritating body and does not become tough and hard to remove, as do occasionally the powders sometimes employed, as that of subnitrate of bismuth. The composition of the ointment used by Dr. Terrillon is as follows:

℞ Vaselini, ℥iv;
Amyli, ℥iv;
Acid. tannic., ℈iv.—M.

This ointment has a peculiar pasty consistency, which permits of its introduction by means of the tube above described. The quantity introduced should be from a drachm to a drachm and a half. The possibility of employing this method of treatment from the beginning, the relief gained by the rare introduction of an instrument, and the fact that the patient declares that no pain or inconvenience is felt, give it the advantage over other methods hitherto

employed. Dr. Terrillon gives brief notes of some twenty cases coming under his notice in which this plan of treatment has been applied with success.

INTUSSUSCEPTION OF THE INTESTINES, WITH EXPULSION OF FORTY CENTIMETRES OF INTESTINE—RECOVERY (Dr. Grosoli, *Giornale di Medicina Militare*, November, 1880, p. 1190; from *L'Indipendente*, No. 32, 1880).—Boy 10 years old, after having eaten some limes and oranges (seeds, skin, and all), was seized with violent pains in abdomen. Castor oil administered by his mother without causing any passage. Pains continued, and soon associated with vomiting. Dr. Grosoli called in. He prescribed an oleaginous purgative and a clyster of senna and common salt, but without success. Symptoms increased in violence, and vomiting of fetid, sedimentary matter set in. Belly extremely tender to touch. Leeches, clysters, hypodermic injections of morphia and atropin, warm cataplasms, cold applications, warm baths of the whole body, and electrical currents had no effect. For twelve days the patient suffered agony, being sustained in the mean time by nutritive enema. Finally, the doctor administered to him thirty grammes of mercury. Two hours after, bowels moved for the first time. Expulsion of much flatus and fecal matter mixed with blood and mercury. He then commenced to improve, but the pains ceased only with the expulsion of a membranous substance having a gangrenous odor. Next day, expulsion of forty centimetres of small intestine. For fourteen days following, slight pains in abdomen were present, with occasional ejection of pieces of intestines. In a month after, he was able to leave his bed. W.

TRANSFUSION OF BLOOD BY THE PERITONEAL CAVITY.—Dr. Lava (*Cbl. f. Chir.*, 1881, p. 176; from *Osservatore, Gaz. delle Cliniche*) gives an unusual case of blood-transfusion into the peritoneal cavity in the case of a patient suffering with progressive pernicious anæmia with hyperleucytosis. Two hundred and ten grammes of defibrinated blood were injected by means of Castieau's apparatus. Death supervened forty-one hours after the operation, and at the post-mortem examination diffuse sero-fibrinous peritonitis was found, together with anæmia. In the intestine were found a large number of anchylostomata.

APOMORPHIN AS AN EXPECTORANT.—Muriate of apomorphin has been employed by Dr. Carl Beck (*Deutsch. Med. Wochens.*, March 19, 1881) in sixty cases of bronchial catarrh and thirty-one cases of broncho-pneumonia. He finds that under its use the secretion becomes rapidly thinner and more fluid, and in broncho-pneumonia particularly the thick, tough plugs which close the air-tubes and slowly suffocate the patient by carbonic-acid poisoning are loosened and discharged. The dose of apomorphin is $\frac{1}{64}$ grain for young infants, increasing the amount by $\frac{1}{120}$ grain for every year. For adults the following formula is recommended by Beck:

℞ Apomorphii muriat., gr. $\frac{9}{10}$–j$\frac{1}{4}$;
Acidi muriatici diluti, ♏xv;
Aquæ destillatæ, f℥xxx;
Syrupi simplicis ad f℥iv.—M.

Sig.—Tablespoonful every second, third, or fourth hour. Half this dose is the average for children of three to ten years, every hour.

DRAINAGE FROM THE BLADDER IN THE OPERATION FOR STONE, ESPECIALLY THE HIGH OPERATION.—Trendelenburg (*Cbl. f. Chir.*, 1881, p. 172; from *Berlin. Klin. Wochens.*) alludes to the fact that in many cases of large and old calculi the ureters themselves are dilated, so that the valve to the bladder is opened and cystic inflammation can very easily extend towards the kidneys. The urine, mixed with débris, blood, etc., may also penetrate to the kidney and arouse pyelonephritis. For this reason Trendelenburg urges the employment of drainage-tubes for eight to twelve days after the operation, washing out the bladder once with disinfecting fluids, but not again. This procedure should be followed in all cases, but especially after the high operation.

A NEW INSTRUMENT—THE VEIN-BROOCH IN VARIX.—At a recent meeting of the Clinical Society (*Lancet*, vol. i., 1881, p. 561) Mr. Douglas showed an instrument of his devising, and which produced flat pressure on varicose veins and varicocele by means of a horn spatula, or one made of horn and steel, with a grooved needle riveted to the eye-end and fastening at the point, after passing under the vein, by a catch like a brooch or safety-pin, giving very little pain, and (unlike the old torsion of wire or silk ligature) producing no constitutional disturbance, but obliterating the vein with certainty, and without subcutaneous division.

MEDICAL TIMES.

PHILADELPHIA, JUNE 4, 1881.

EDITORIAL.

ANÆSTHESIA.

WE desire to call especial attention to the article which appears in our present issue from the pen of that clear-headed young surgeon, Dr. Roberts, and to the discussion thereon, whilst making editorial remarks upon the subject. At the meeting of the County Medical Society various speakers agreed with Dr. Roberts in magnifying the dangers attending the administration of anæsthetics; but we are impressed with the marvellous safety that attends even their careless use, provided only that the most innocuous among them are selected. The dangers which surround chloroform have been too frequently written about and have been too often and too tragically exemplified to need further comment. He who still persists in the habitual employment of chloroform seems to us beyond the reach of argument or human speech. We let him alone. With nitrous oxide gas and with ether, how few are the deaths in proportion to the administrations! In the city of Philadelphia chloroform has produced death, to our personal knowledge, several times; ether has certainly been used more frequently than the other agent, but we have never known of a case in which death was certainly or even fairly attributable to this anæsthetic. Fifty inhalations of ether a day is hardly an over-estimate, which would give, in the last thirty years, five hundred and fifty thousand administrations for this city, and not one death unimpeachably produced by this oxide of ethyl. Possibly this estimate of the number of administrations may seem exaggerated; but cut it down beyond all reason, and remember the heart- and lung- and kidney-affections which so often exist uncared for, the towel sopped with ether, the utter carelessness so frequently seen in the operating- or sick-room, and it is marvellous not that there have been one or two deaths very doubtfully attributed to the agent, but that there has been so clean a record. Is it too much to claim that drunkenness from ether is much safer than a drunkenness of equal degree from alcohol?

It cannot be admitted that in either of the cases reported by Dr. Roberts the death was positively attributable to the ether. In one case a large dose of chloral was given,—an amount, indeed, which has produced death very much as was caused in the case here reported without ether having been given at all. In another case the man died, after recovery of consciousness (*i.e.*, after the symptoms of anæsthesia had passed off), from sudden pulmonary œdema. The kidneys were not examined after death; there was at least enough during life to suggest the possibility of their having been diseased; sudden pulmonary œdema is common enough in contracted kidney, not one of the dangers usually attributed to anæsthetics: surely, without further discussion, this case may be ignored.

The first case reported by Dr. Roberts is more pertinent; and yet it does not bear examination without flinching. Every man who dies during anæsthesia does not necessarily die from the anæsthetic. It is certainly possible for an anæsthetized patient to die from hemorrhage; it is equally certain that patients not anæsthetized have died under the knife from shock, and there is no proof that anæsthesia abolishes shock.

The case narrated by Professor Smith in the discussion was very pertinent. The operation was similar to that performed by Dr. Levis; result fatal in each instance. No anæsthetic having been given in one case, death is registered from shock; ether

having been given in the other, death is attributed to it. If only Professor Smith's case had happened a little later in time, after instead of before anæsthetics had come into vogue, we should have had two cases of death from anæsthesia.

The symptoms during the last hour of life in Dr. Roberts's case are very interesting and instructive. Contrast them with scenes so often witnessed in the practice of chloroform anæsthesia. A cry from the surgeon giving the agent, or from a by-stander, announces that the pulse has suddenly failed, or the well-known, peculiar pallor has in an instant spread like a death-cloud over the face of the victim; the rush, the struggle, the quick return to life, or the plunge into death. In Dr. Roberts's case, a slow failure of the pulse, a gradual sinking into the grave, a whole hour of doubt. Years ago, when resident in Pennsylvania Hospital, we saw two men who had been badly burnt some miles away, had run of their own accord straight to the hospital, and got into bed clear in intellect, but with failing pulse, to become in a few moments unconscious, with pulse growing weaker, and to die in an hour or two: not death from ether, but from shock.

The lesson we would draw from the facts brought forward by Dr. Roberts is not to be afraid of ether and to allow pain to reduce vital power, but to remember that at least as much care is necessary in using ether as would be given to making a man drunk.

LEADING ARTICLES.

PARASITIC ANÆMIA.

THE occurrence of a mysterious and fatal form of anæmia among the laborers in the St. Gothard tunnel a year or so ago, and the subsequent discovery of intestinal parasites as the cause of disease in these cases, have lent renewed interest to the investigations made by a few well-known observers which had previously failed to gain that amount of general attention which their importance deserved. Of late, interest in this subject has revived, and we find in a recent number of *Schmidt's Medicinische Jahrbücher* a general résumé of our knowledge, by Dr. Meissner, of Leipsic.

Although anæmic symptoms are those most prominent and to which most attention has recently been drawn, yet there are other forms of disease so closely connected with parasitic infection that it seems proper to consider them together.

Among the parasites involved are hæmatozoa and intestinal parasites. Of the hæmatozoa those of most importance are the *filiaria sanguinis hominis*, and the *bilharzia hæmatobia*. The first of these has been very thoroughly studied by Manson, of Amoy, China, and Bancroft, of Brisbane, Australia. The filiaria, while it may at times be present in the blood without giving rise to any symptoms, at other times appears beyond question to be the cause of chyluria, elephantiasis, etc. The mode of its action would seem purely mechanical. The parasite lives in the blood- or lymph-channels, and its accumulation at a given point gives rise to lymphorrhagia or inflammation. Two curious facts have recently come to light regarding this parasite. One is that the mosquito acts as a carrier: sucking the filiaria with the blood of an affected person, it afterwards deposits the ova or embryos, which have meantime hatched, in the water when it lays its own eggs. These embryos are then swallowed in the drinking-water by another victim; and so the circle of disease is completed. Another and a very curious fact regarding the habits of the filiaria was lately discovered; this is, that it is a nocturnal parasite. During the day the filiariæ lie dormant at some point in the victim's circulation, but at night they sally forth and rove the currents of the blood the night long.

Bilharzia hæmatobia were found by Dr. John Wortabet, of Beirût, in patients who had been using bad drinking-water. Strangury and hæmaturia were among the earlier symptoms, followed by an eruption of blebs (?) resembling "Delhi boils," which only healed after six months. The patients enjoyed apparently good general health, but were weak and nervous. Ova and a few fully-developed parasites were found in the urine. Bad drinking-

water, especially that of Syria and Egypt, appears responsible for the occurrence of this parasite, which produces its evil effects by collecting in the vessels and parietes of the hepatic and renal system and giving rise to hemorrhages and abscesses. In several cases a prolonged stay in London cured patients who were again attacked on returning to Egypt.

Among the intestinal parasites which give rise to general symptoms, the *Anchylostoma duodenale* is best known, although it has been only recently the subject of careful investigation. Allusion has been made to its occurrence among the workmen of the St. Gothard tunnel. A recent communication from Dr. Bugnion, of Geneva, in the *British Medical Journal*, throws more light on the subject. The anchylostoma belongs to the same order as the trichina, the oxyuris, and the ascaris lumbricoides, but instead of feeding on the contents of the bowels it attaches itself to the mucous membrane of the duodenum and sucks blood like a leech. The repeated intestinal hemorrhages produced by its attacks may be considered as the principal cause of the aggravated anæmia and increasing weakness which are generally observed in the victims of this parasite. In the case of the workmen in the St. Gothard tunnel, no fewer than 117 deaths had taken place up to June, 1880. The difficulty of diagnosis was enhanced by the refusal of the authorities to permit post-mortem examination of the patients. The diagnosis once made, treatment of the usual parasiticidal character becomes available, and is followed, if timely, by good results. The symptoms of this peculiar form of anæmia are at first those of a chronic gastro-intestinal catarrh. The affection begins gradually, with loss of appetite, constipation, pain and weight in the stomach. Then follows loss of energy and spirits, with suicidal inclination. The color of the skin becomes changed to a peculiar waxy yellow, and loss of pigment (peculiarly noticeable in the negro) is marked. The special senses are dulled, cardialgia, cramps, headache, sleeplessness, tinnitus aurium, dyspnœa, palpitation and dizziness occur on exertion. There is a blowing sound in the arteries and sometimes in the veins of the neck. Later still the lack of appetite changes to a craving for food, often of a loathsome sort. Bloody and excessive stools supervene; anasarca, œdema of the lungs, cramps, and cardialgia close the scene. Post-mortem examination shows, in addition to the appearances commonly presented,—extreme anæmia and bloodlessness,—foreign bodies, coal, balls of earth, etc., in the stomach. The intestinal mucous membrane is swollen, and shows numerous extravasations, with occasional ulcers. Under a lens the marks of the teeth of the anchylostoma can be perceived, and, if the examination has been made within a short time after death, the living worms, to the number of eighteen to twenty-four over the space of about two-thirds of a square inch. The parasites themselves are about one-quarter to one-half inch in length. The prognosis of the affection is favorable in its earlier stages, provided appropriate remedies be employed. These should be both of a hygienic and a medicinal nature. Anthelmintics, santonin, camphor, assafœtida, turpentine, kousso, pomegranate, etc., are first to be employed; then iron, bitter tonics, astringents, and sometimes diuretics. Above all, however, change of air and water (the latter should always be filtered), and the use of strengthening diet, with alcoholic stimulants, are of use.

The occurrence of *Anguillula intestinalis* and *A. stercoralis* in the dyspeptic or endemic diarrhœa of Cochin China has been shown by several observers, and there is strong reason to believe this parasite to be the cause of the affection.

This whole subject of parasites of the blood and intestine, although very little examined into as yet, promises much information, particularly as to the causes of obscure tropical diseases; and the fact that parasitic anæmia has been found so far north as the St. Gothard indicates that these affections may not be confined to tropical and sub-tropical countries alone.

CORRESPONDENCE.

LONDON LETTER.

IN my last letter the question of meeting homœopaths in consultation was discussed in reference to the late Lord Beaconsfield. My opinion that such consultations are not desirable was then expressed with my usual outspokenness. The matter has occasioned an explosion of opinion, both among the laity generally and the profession. The most an-

tagonistic position was taken up. The laity approved highly of Dr. Quain's action; the profession has as strongly disapproved of it. The laity evidently wish to be allowed unlimited freedom to flirt with homœopathy when they list, to be serious with regular scientific medicine when the danger of death looms up. They are very indignant, indeed, at the medical profession daring to assert any opinion of its own instead of humbly bowing the knee and feeling rebuked for having ventured to think for itself. On the other hand, the profession has its opinion on the matter, and a discussion has gone on about the subject both in the *Lancet* and the *British Medical Journal*. The voice of the profession is distinct and articulate; it will have none of these compromises, none of these left-handed alliances with an immoral section of the medical world,—no concubinage with bad characters. Let the laity say what they will, the profession is "solid" on this matter. Of course apologists are found for the eminent personages who are impeached, as might be expected. I took part in the discussion in the *British Medical Journal*, and impugned the conduct of the ex-President for the advice he gave. Every one has agreed, so far, with this view, that "the President was an outsider, and under no pressure," and ought to have remembered the College he represented, and its obligations—and with that his own—to the profession at large. Of course it is to be deeply deplored that at this time, when the evidences of the profession being of slight social account have been unpleasantly frequent, so abject a position was assumed by prominent members of it. But some of the individuals who have hitherto had more of their own way than was either good for themselves or for the profession to which they belong in the councils of the College will now have to abdicate, having been detected, or found out, preaching one doctrine and practising another. Of all kinds of imposture the most detestable is that of the Pharisee, who judges others severely yet omits to live up to his standard and professions himself. There has been sufficient of the cleansing of the outside of the platter; it is polished enough to reflect some goodly pictures of sundry individuals posing before it. What is now wanted is some sanitary cleansing and disinfection of the contents thereof. This must soon be done, as the profession is awakening to the conviction that it has been blinded and played fast-and-loose with in its complete confidence.

But this is not the only matter of interest to the profession brought out by the late ex-premier's illness. It was curious how his condition varied and oscillated with the weather-cock. When the wind veered from the east and northeast into the west, the aged senator picked up; when the wind went round to the east again, he drooped. The temperature of the room might be maintained artificially, the air might be kept moist by bronchitis-kettles, but nevertheless the nor'-easter made itself felt. The keen nipping wind found an entrance in spite of everything that acute human intellects could devise, and the venerable Oriental sank under the east wind at last.

The most useful agent, it appears from the daily press, for giving him relief from his asthmatic paroxysms was "Himroth's powder,"—not a remedy in the English Pharmacopœia, but an American quack or secret preparation. Anyhow, it appears, it did good; and there was a sense of fitness in a long belief in homœopathy terminating and culminating in a quack preparation. But to revert to the east wind. It certainly exercised a most potent influence upon his lordship; it certainly does exercise a curious malign influence upon the inward processes of nutrition and the metabolism or transformation of albuminoids within the body. Many years ago a patient with acute nephritis was recovering very satisfactorily, the appetite was returning and the strength coming back, when the wind veered to the east, and with it the prospect clouded. Uræmic poisoning set in; the patient was purged, sweated, and even bled, with temporary relief, but all in vain; she sank. Since then an east wind has been regarded as distinctly dangerous in many cases. Nor has an increasing experience modified the suspicion with which the veering of the wind-vane to the east has been watched and noted.

It seems in some way to pervert or interfere with the transformations going on in the liver, and to modify them so as to charge the blood with waste. The expression a "bilious chill" has long been adopted here to signify a condition where a chill has operated malignly upon the liver and its processes, perverting them and disturbing the economy. The effect of the east wind and its variations upon a patient of my own was very instructive. In September last he presented himself with dropsy in the legs, not extending above the knees. The liver was distinctly enlarged, and there was a history only too clear of considerable alcoholic indulgence. The heart was dilated, and its action irregular. On digitalis and strychnine he improved splendidly, a mercurial pill twice a week, with a purgative of sulphate of soda and Rochelle salt next morning, being taken to sweep away the waste out of the blood, and so to lessen the arterial tension. The diet was strictly regulated, and albuminoid matters given but sparingly. The progress was instructive. Hand in hand with the general improvement a reduction in the bulk of the liver could be observed, until it was reduced a long way towards its normal size, while it seemed to possess almost unimpaired functional activity once more. Such was the improvement that the patient was lost sight

of till March 29, when the east wind had been blowing some time. When seen at that date, there was consolidation of the lower lobe of the right lung, without, however, any general disturbance of the health. The consequence of this was increased fulness of the liver, and that again was followed by œdema of the legs. The bulk of urine fell remarkably. For ten days I did not see him, being away in the country. On my return, I found the dropsy had mounted above the knees; the liver was as large as when first seen; but the consolidation of the lung had scarcely progressed at all. During this time the east wind which finished Lord Beaconsfield blew keenly. The patient was purged with elaterium and compound scammony powder, and well sweated in Sir James Simpson's bath of lemonade-bottles full of hot water with damp stockings over them. Just at this time the wind veered, and all went well. The free watery motions, the profuse sweatings produced by the bath, arrested the progress of the advancing dropsy. At the same time, carbonate of ammonia, with full doses of tincture of nux vomica and small quantities of digitalis, was given every six hours. The dose of digitalis would also have been full, but he was one of the rare (in my personal experience very rare) cases where digitalis in full doses has not been tolerated, and the tincture was given in eight-drop doses only, this being compensated, as far as possible, by twenty-drop doses of nux vomica. Under this treatment the bulk of urine rose, but not to the normal amount. The case remained stationary for a few days, except that the lung kept clearing up very satisfactorily, considering all the circumstances of the case. Then the wind veered again. The first effect was some vomiting of bile, with anorexia. Hitherto the appetite had remained good, and the digestion effective. On the whole, though gravely and seriously ill, the case was not without hope. But the wind kept steady. The urine first ceased to increase, then it fell. The patient felt unequal to the bath, but continued the purgative. As the urine fell, the dropsy mounted, climbing into the prepuce. This change for the worse under the active treatment adopted was ominously suggestive of some new departure. The question of making punctures in the legs had been kept in view, but my experience of it had scarcely been encouraging. To do so would be to lessen the dropsy, but it did not necessarily follow that this would increase the renal secretion. For it was obvious that the fall in the bulk of urine, and the increase of the dropsy, were consequential to a something which stood in a causal relationship to both. It was but too evident that this must be in the veins; some block there was obstructing the renal flow as well as increasing the fluid in the lower extremities. Besides, too, the urine became densely albuminous at this time.

This view was in accordance with Sir James Paget's observation that phlebitis is common in the subjects of perversion of the function of the liver. The indications were not those of pure dropsy: the skin was dusky and brawny, and not intensely white as it is usually, nor did the surface "pit" as it ordinarily does. "The limb thus enlarged feels œdematous all through, but firm and tight-skinned, not yielding easily to pressure, and not pitting very deeply." This was a complication which pretty well blotted out the little prospect of life that remained. I thought of putting in some of Southey's drainage-tubes, as about all that remained to be done, but deemed it well to try the effects of some needle-punctures first. A drop of fluid only followed each puncture, and there was no weeping. The result was then utterly unsatisfactory, and the prognosis became very dark. Yet the general condition was surprisingly good. The appetite was fair, the intellect as unclouded as in the days of perfect health; the patient was sitting up in his chair every day, looking very well. He could walk alone and unassisted. It may be remarked that he inherited as magnificent natural powers and constitution as were ever possessed by a "border-man," usually regarded as a race exceptionally strong. He came of a hardy race; and the prospect, bad as it was, did not even affect his demeanor. He saw some friends in the evening, chatted and talked, had a very good night (comparatively), felt well, and enjoyed his food, and his breathing was somewhat less embarrassed than it had been. He walked from one room to another, sat down quite cheerfully; his wife turned away to arrange something in the room, only for a brief while; when she looked round, he was gasping for breath, and died immediately, with the dark flush of asphyxia on his countenance. It was clear the exertion had dislodged a clot out of the internal veins, which had washed through the right heart and plugged the pulmonary artery.

Now, this case is worthy of consideration as to its phenomena and the result. For, in my experience, such a termination had not previously occurred. The legs looked unusual for cardiac dropsy, not being white and pasty, nor pitting on pressure to any extent, but brawny. The liver was evidently much affected by the change of wind; and the phlebitis was consequent upon further disturbance, as indicated by the vomiting of bile. The urine threw down a dense cloud of lithates after standing some time; but that is common enough in dropsy when the function of the liver is deranged. The evidence was furnished rather by the general disturbance and the subjective sensations of the patient than by any one individual or particular sign. But when the wind went away from the east he made headway; when the wind veered the case backed. This occurred more than once, and the patient was so convinced of the asso-

ciation that he persisted in declaring that if the wind kept in the east it would kill him. Now, the same perturbations were seen in my hospital patients generally during the long-continued east winds of this spring and last year. They found out every one "who had a liver." Patient after patient showed a bile-stained tongue, the hue being noticeable even when there was no fur upon the tongue, if placed in a side-light; there was the concomitant bad taste in the mouth on awaking in the morning. As a rule, too, there was disturbance in the bowels, and a deposit of lithates in the urine. Such are the generally accepted evidences of derangement of the liver. In such persons as were the subjects of grave organic changes in the liver, of course the disturbance was more pronounced than in those comparatively well.

How these disturbances are brought about we cannot yet say; but thus far we may fairly assume,—when the albuminoids of our food are rendered perfectly soluble by the digestive act in the alimentary canal, they pass therefrom into the blood of the portal vein. From thence they pass into the liver and undergo further change, so as to be elaborated and fitted for the nutrition of the tissues in the form of the albumen of the liquor sanguinis. Some are split up apparently right away into urea, instead of undergoing further elaboration; that is, instead of proceeding on the normal further course of the crude product of digestion, they are turned aside to undergo a retrograde metamorphosis. Probably a considerable proportion of the urea we pass has such a genesis. The excess of proteid material is broken up into urea. This production of urea in and by the liver is now generally recognized by physiologists. At the same time, the taurin and glycogen, which unite with the cholic acid in the formation of the bile-acids of man, have a chemical formula bearing a generic resemblance to those of urea and uric acid. Well, when the liver is disturbed, it would seem that instead of the normal transformation of surplus albuminoids into urea the metabolism is in the direction of uric acid and bile-acids. Nor is it difficult to comprehend how this perversion is brought about, when the likeness of the chemical formulæ is borne in mind. The presence of these products in excess in the blood excites various disturbances, and, among the rest, the phlebitis which is so serious. The east wind penetrates into houses, and even into the internal processes of the organism, and disturbs them. The influence upon the liver in this case was unmistakable and, at the same time, most disastrous to the patient's prospects, as the event proved. Of course the case was a very serious one even without the phlebitis; but with it added it was impossible for the organism to carry the burdens imposed upon it. The lesson of the case is one which carries weight with it,—viz., to bear in mind the function of the liver, and with that the derangements commonly met with. When the arrangements for the dehydration of grape-sugar in the portal vein into glycogen, or the hydration of glycogen once more into grape-sugar by the ferment of the liver, are perturbed, then we find the excess of sugar in the arterial blood passing off in the urine, producing glycosuria,—in bad cases the diabetes of our text-books. Far more commonly the disturbance is in that part of the liver-function which is concerned with the metabolism of proteids, by which the crude albumen formed in the alimentary canal is elaborated into the perfected albumen of the liquor sanguinis, or transformed by an oxidizing process into urea or a bile-acid. Consequently, in some cases we find that the transformation is perverted and we get lithic acid produced, while in other cases there is an excess of bile-acids produced. Looked at from this point of view, we can see how lithiasis may be brought about without indulgence in albuminoid food to excess, but by a sort of vice in the liver which is inherited in those cases of hereditary gout where lithic acid is formed on the slightest departure from a strict dietary, the most scrupulous self-denial. When more albuminoids are taken than the liver can deal with satisfactorily, then lithic acid is also formed. In either case the kidneys in time become changed by the lithic acid and lithates in the blood; and so we can see how kidney-disease is the consequence of lithiasis and marks the later stages of the malady. This is the view of gout which must obtain in the future.

J. Milner Fothergill.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

At a conversational meeting held at the hall of the College of Physicians, Philadelphia, February 9, 1881, Dr. Albert H. Smith, President, in the chair, Dr. John B. Roberts read a paper on "Ether Death: A Personal Experience in Four Cases of Death from Anæsthetics." (See page 545.)

DISCUSSION UPON ANÆSTHETICS.

Dr. Henry H. Smith inquired whether the patients had taken food shortly before using the anæsthetic agents.

Dr. R. J. Levis said that in three of the cases no food had been taken for several hours.

Dr. Laurence Turnbull observed with much force that no anæsthetic can be used with absolute safety. Ether produces inebriation like alcohol, and the patient must be kept warm while under its influence, or the temperature will sink below the normal, the skin become

cold and clammy, with symptoms of collapse. The pulse-rate falls, the breathing becomes embarrassed, and an increase of secretion takes place in the lungs, and death occurs from pulmonary œdema and respiratory paralysis, just as in drunkards who are exposed to cold. On account of the similarity of their action, alcoholic stimulants should not be given where a patient appears to be sinking after ether administration. This is the difference between ether and chloroform: under ether the pulse rate is regular and becomes slower, while under chloroform it becomes irregular, as is shown by sphygmographic tracings made by Kappeler. In ether administration the respiration should be watched; in chloroform, the pulse.

Primary deaths from ether are very rare, and that reported by the lecturer was the first one that he had heard of in the city, although another had been lately reported in Cincinnati. In the case referred to this evening, he regretted that the heart had not been carefully examined and the state of the secretions had not been noted. He believed that the state of albuminuria added increased risk to anæsthesia, and he would hesitate to give ether when the amount was large, and would seek to reduce it first by remedies. He criticised the treatment of the patient after the operation, saying that artificial respiration and warmth would have formed a better means of treating ether collapse than alcoholic stimulants. Atropia, also, should not be given in doses larger than one-sixtieth of a grain, nor too frequently repeated.

Dr. Geo. Hamilton said that if albuminuria is a contra-indication to the use of anæsthetics, he wondered that there were not more deaths, since the condition is quite prevalent.

Dr. Levis remarked that the neglect of artificial respiration had been pointed out, but if the members would look at the report they would notice that the breathing never failed until the last, while the pulse was quite weak. After the operation the patient seemed to be in a quiet anæsthetic sleep, but the weak pulse had attracted Dr. Roberts's attention.

Prof. H. C. Wood endorsed Dr. Turnbull's remarks about alcohol and ether, and said that the more closely their effects on the lower animals are studied, the more closely are they seen to correspond. Atropia and digitalis, on the other hand, are of value, but their effects have been greatly magnified; as in single doses they could be given in much larger doses than we are accustomed to, and without any harm.

In considering the causes of death after ether, we must not forget that patients sometimes die of heart-failure, collapse, or shock after operations where no ether has been given. Cases of severe burns, or of surgical operations, frequently rally after the operation, but die afterwards with secondary syncope. The danger of shock is very much reduced where the anæsthetic is used, and in cases of albuminuria the danger from shock without the anæsthetic might be greater than from the ether. Moreover, the amount of albumen in the urine is not an index of the increased risk, for in some cases of contracted kidney the proportion is very small. In the treatment of collapse after ether he recommended the use of ammonia, digitalis, and proper attention to the position and covering of the patient.

Dr. Schapringer had observed that the peculiarity in the case of Dr. Roberts was the heart-failure after ether; but the case was very different from the fatal cases of sudden heart-failure following the administration of chloroform, as it came on gradually and was accompanied by a weak, rapid pulse. He had given chloroform very frequently, and had seen no bad results from it, except in one case, where an assistant had given too much, and some difficulty was experienced in reviving the patient by artificial respiration, slapping his face with a wet towel, which is a good way of supplying the brain with blood and keeping up the circulation.

Dr. W. R. D. Blackwood thought that the danger of anæsthesia is often underrated. Many practitioners give chloroform for the most trifling operations, such as pulling teeth or opening a felon, which is unjustifiable in any case, and criminal in the hands of dentists and other uneducated or semi-medical persons. He could not agree with the lecturer that chloroform should be abolished, as he had used it in many hundreds of cases, while in the army, without any accident. He had seen a man die on the table from fright and shock before anything had been done to him; and here the anæsthetic would have been blamed if administered. He had given chloroform to men apparently dying, in order to perform amputation, and the patients afterwards recovered. Chloroform is the best anæsthetic we have, and is safe, provided that it is given with proper care. In all his field-experience he never saw any difficulty with chloroform; but it was always given in well-ventilated tents or in the open air. The only trouble he had observed with other operators was where mixtures have been used, the rates of evaporation of the ingredients being very different. For the resuscitation of such cases he recommended the introduction of a piece of ice into the rectum. Ether is, however, in ordinary civil practice the preferable agent, and is always safe.

Dr. Levis introduced Dr. West, who was invited to give a further account of the fatal case, which had been under his care previous to the operation.

Dr. West said that the patient had been under his care for about eighteen months previous to her admission into the hospital. After three months' treatment for uterine disease, she had an attack of rheumatism, and

subsequently a relapse; she continued sick for about three months. She also complained from time to time of dysuria, but no albumen or sugar was detected in the urine; but from the pains in the kidneys the speaker inferred that she had chronic nephritis. She also had occasional cardiac palpitation, but had no other evidence of heart-trouble. Twice before admission into the hospital she had taken ether without bad symptoms, although the symptoms of cardiac trouble had previously existed.

Prof. Bartholow said that the prevailing impression of the profession of the comparative safety of ether over chloroform makes a careful investigation into fatal cases necessary, in order to ascertain all the causes contributing to the result, so as to avoid them in the future. He had been struck with the general neglect by the profession of the observations upon anæsthetics made by Bernard some twenty years ago, who found that anæsthesia could be obtained more easily, maintained with less danger, and after-recovery made more sure, by the administration of morphia just before the anæsthetic is given: by this means the stage of excitement and rigidity is avoided which constitutes one source of danger. He also claimed that by this mixed anæsthesia the sensibility of the larynx was obtunded so that the agent could be given with less trouble. He also was satisfied that less of the agent was required, and the stage of anæsthesia was prolonged. Nussbaum adopted the method, but administered the morphia after the patient was under the anæsthetic influence. By the method of mixed anæsthesia the danger is lessened; for nothing could be more certain than that morphia sustains the action of the heart. It is therefore a matter of surprise that the profession at large has taken so little notice of this method of Bernard, especially when endorsed by Nussbaum. It is true it has been advocated by Wm. Warren Green, who claimed it as his own, and it was also taken up by Dr. Reeve, of Dayton, who wrote a paper on mixed anæsthesia. The morphia should first be given by the hypodermic plan, and the anæsthetic subsequently; less of the chloroform will be required, and the danger of heart-failure will be reduced.

He had also been impressed with the statement that the condition of anæsthesia is a condition of danger. All the functions of life are suspended except circulation and respiration, and these are in a more or less damaged condition. Our attention, then, should not be directed to the search after new anæsthetic agents so much as in the direction of making those we have safer. He did not believe that ether is necessarily safer than chloroform. The agent that is used the most frequently would naturally yield a greater number of deaths, and when ether comes into more general use more deaths from it may be anticipated. If anæsthesia is a condition of danger, then the danger is present with ether as well as with chloroform.

In the treatment, he fully agreed with the statement of the inadvisability of giving alcohol in any form, especially hypodermically: as ether is a derivative of alcohol, and has the same effect as a respiratory paralyzer, it would only be adding fuel to the flame. Nor could he agree with the treatment by the injection of ammonia. Where there is danger of death from paralysis of respiration, there are two means of stimulation far superior to medicine: they are artificial respiration and faradism, which are far better in these cases than the so-called cardiac stimulant, atropia. If the cardiac ganglia are beginning to fail from exhaustion, the cardiac stimulant may meet with no response, or may prove injurious, for its first effect is that of stimulation; the second, exhaustion. The heart may be sustained by intravenous injection and artificial heat. He most decidedly protested against the subcutaneous injection of the tincture of digitalis. The action of digitalis is slow, and requires several hours to affect the heart. In a case reported by Boehm, death occurred five days after the administration of a poisonous dose of digitalis, from paralysis of the heart. Digitalis acts by stimulating the inhibitory apparatus, and not by giving increased power to the cardiac ganglia.

Dr. Huidekoper endorsed mixed anæsthesia.

Dr. Toboldt suggested nitrite of amyl in syncope after anæsthetics.

Dr. Henry H. Smith was present at the first administration of ether in this city. In 1846 he administered it for Prof. Horner, in the case of a woman whose breast was to be amputated: the patient was fully anæsthetized, to the great delight of the class. In spite of opposition and warnings of threatened litigation, they continued to use it at the clinic. The surgeons of Pennsylvania Hospital spoke very strongly against it, and one of the more prominent would not consent to be present where it was used. A leading obstetrician warned him that, as it was against the teachings of the Bible, it should not be used.

The first case reported by the lecturer was not a death from ether, but from shock. He recalled a case in which *brisement forcé* had been practised upon an anchylosed knee, without any anæsthetic, and the patient died twelve hours afterwards from shock. The state of anæsthesia is not without danger, but with proper precautions it is perfectly safe. The patient should not be smothered with a towel, but allowed to have fresh air. A bottle of ammonia should always be convenient, so as to allow the patient to inhale it if the breathing is imperfect. He had given ether for the last thirty years to cases in his clinic, and in

private practice, amounting to several thousand, without the slightest cause for anxiety. Even in cases of valvular disease of the heart, and in old age, he had used it without bad results. He insisted upon the importance of not allowing the patient to have any solid food on the day of operation, not since the evening previous.

He believed the danger to be greatly enhanced where mixtures are used. Physicians, moreover, should not be satisfied to use any anæsthetic without ascertaining its purity; the tests being easily applied. As he had no experience in the treatment of dangerous symptoms following anæsthetics, he would not discuss the subject, but said that he questioned the utility of hypodermic injections, and would prefer inversion of the patient, artificial respiration, and frictions of the skin.

Dr. Chas. B. Nancrede observed that in the popular estimation the danger from anæsthetics could not be very great, as they are generally intrusted to the youngest resident physicians in the hospital, and he had seen them thus given in the most reckless manner, so as to nearly strangle the patient. He was surprised that there were so few deaths.

One point not referred to was the effect of the ether upon the broncho-pulmonary mucous membrane. It is well known to act as an irritant, and to cause increased secretion. Under such circumstances, there is increased difficulty in forcing the blood through the capillaries, and the heart's action is reduced; this apparent weakening of the heart is not due to direct depressing action of the ether, but is caused by the difficulty in the capillary circulation. Artificial respiration will relieve this trouble.

As regards shock, he doubted if ether prevented it, as had been asserted. After a major operation he had seen great irregularity of the heart, due to the operation, and not the anæsthetic: if the patient had died, he would not have perished from the ether, but from the operation; he would be more likely to die without the ether.

In conclusion, he condemned the practice of pulling the tongue forward and holding it pulled out of the mouth, as this manœuvre by fixation of the larynx rather interfered with than assisted breathing; the method of pulling the jaw forward by placing the thumbs behind the angle on each side, on the other hand, greatly favors respiration.

Dr. O'Hara did not consider albuminuria as a contra-indication to anæsthesia, especially in cases of convulsions. The greater danger of chloroform over ether may be explained by its different specific gravity. The patient reported by Dr. Roberts may have had simply a weak heart; the absence of murmur is not conclusive evidence that the heart was healthy.

Dr. Albert H. Smith in obstetric practice preferred chloroform to ether, because it acted more promptly in relieving pains, but for prolonged operations he used ether and morphia, as recommended by Bernard.

Dr. John H. Packard referred to the use of nitrous oxide preliminary to the administration of the ether. He had not seen any ether deaths in healthy persons; they were all debilitated or reduced by chronic disease; among the chloroform deaths, however, some were included who appeared to be perfectly sound and healthy. Perhaps when ether has been given in as many cases as chloroform there will be just as great a mortality. In cases of death, the mere phrases "disorder of the heart," "diseases of the lungs," etc., are not sufficiently explicit; the profession wants to know what diseases of the heart, what was the condition of the lungs, as whether emphysema, chronic bronchitis, or the like. He had given ether in old drunkards with good results, and also in cases of albuminuria, which did well.

Secondary shock may follow operations after chloroform as well as after ether, and occurred before the introduction of anæsthetics.

In giving ether, no air should be admitted, but only ether vapor. If epileptiform convulsions occur, dash cold water in the face of the patient, and no bad results will ensue. The ether should be given on a towel folded into a cone, with only a small aperture at the top. In conclusion, he called attention to the similarity of the measures adopted in the treatment of Dr. Roberts's case and that occurring recently in Cincinnati.

Dr. A. G. Read believed that the very large amounts of brandy which had been thrown into the rectum and under the skin in the case just referred to were enough to cause a stoppage of respiration in a healthy person.

Dr. Chas. K. Mills called the attention of the Society to the recently-reported experiments of Brown-Séquard in producing general insensibility by dropping chloroform upon the skin. He thought it possible that in some of the cases of unfavorable effects in man the result might be explained by the local action of the chloroform.

Dr. Jos. Hearn, as anæsthetizer for the Jefferson Medical College, had given chloroform in many thousands of cases in the last eleven years, to young and old, without any bad effect. He advised giving the anæsthetic gradually, so as to accustom the patient to it; it may then be kept up for hours. Where much irritation is caused, it may be due to impure ether; chloroform does not cause such irritation. He always has a wet towel at hand to slap the patient's face as soon as he appears asphyxiated. He watches both the respiration and the circulation. He believed that the danger of chloroform upon the heart had been overrated. The use of morphia prior to operation is generally practised at Prof. Gross's clinic, as it requires less of the anæsthetic. The primary irritant effect of the

ether can be obviated by practising Dr. Bonwill's method of rapid respiration to obtund the sensibility of the mucous membrane.

When the chloroform or ether is carefully given, the danger is comparatively small; the risk is less in the agent than in the mode of administration. He had never seen a death from either chloroform or ether.

Dr. Roberts said that in the case he had reported the question as to whether death was due to shock or not was very appropriate, since the patient was much agitated and very anxious, because a very noisy sailor had been operated upon immediately before she was brought in, which had frightened her very much. Fatty embolism was also suggested as a cause of death; but there was no difficulty in respiration; for the same reason, artificial respiration was not required. The changes in the liver, kidney, and heart explained the fatal result, but they could not be ascertained previous to the autopsy. Ether gives trouble in these cases, perhaps, because so much is taken into the system, and the elimination is very imperfect; but he had reached the conclusion that ether is far safer than chloroform. Schiff and Dalton both use ether in preference to chloroform in their physiological experiments, because so many deaths are caused by the latter. Excluding deaths from mixed anæsthetics, the mortality from ether is comparatively small, since there have been reported only seventeen or eighteen cases in all. Nitrous oxide gas has been used preliminary to the ether with good results; and it has been recommended to give ether prior to chloroform administration. Mr. Dawson, of Leeds, England, was the first, he believed, to attribute the danger of suffocation from the increased secretions of the lungs to the coldness due to the ether in the bronchial tubes. The most recent authoritative statement in regard to anæsthetics was the Scientific Grants Committee of the British Medical Association, who declared chloroform to be the most dangerous, ethidene dichloride next, and ether the least. As matters stand at present, he would rather write upon a death-certificate "Death from ether" than "Death from chloroform."

REVIEWS AND BOOK NOTICES.

ERRATUM.

By a curious typographical blunder, the treatise on "Relapse of Typhoid" reviewed in our last number was attributed to *Dr. J. Pearson*, whereas the author was the late *Dr. J. Pearson Irvine*.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN. By S. WEIR MITCHELL, M.D. Philadelphia, Henry C. Lea's Son & Co., 1881.

On rising from the rapt perusal of this brochure of some two hundred and twenty-five pages, the exclamation which jumped from involuntarily-moving lips was, "A most extraordinary book, upon an extraordinary subject, by an extraordinary man." The title of the book seems to us a misnomer, and unfortunate,—unless it is part of the rhetorical skill of its author to use a title-page as the server of dinners does a dish-cover, *i.e.*, to hide the good things within. There are thirteen chapters in all, and the monotone which runs through the whole wild chorus of nervous perturbations chaotic is hysteria. The volume might well have been called "lectures upon the hysterical demon in his strangest performances."

It is written in the author's supremely happy style, and is a record of a number of very remarkable cases, with acute analyses and discussions, clinical, physiological, and therapeutical. It is a book to which the physician meeting with a new hysterical experience, or in doubt whether his new experience is hysterical, may well turn with a well-grounded hope of finding a parallelism: it will be a new experience, indeed, if no similar one is here recorded. Possibly the most useful portions of the volume are those detailing the management of individual cases. The means adopted and the reasons therefor are so well given that most practitioners will, we opine, be able to learn and apply with great benefit to patients.

Of course there is much temptation to review such a fresh book as this at length, but—During the last war confiscated liquors were sent to the Medical Museum to be converted into alcohol for preserving purposes, and it was woful to see the little quantum of bright liquid that came from the worm into whose capacious still the dozens of champagne had been so grudgingly thrown. Something like this would happen were we to attempt to abstract the present volume. It does not treat of the hard science of the profession to be densely formulated in a few words, but it is a sparkling clinical discussion of a very rich experience, and as such has a value not to be melted out of it.

COMPENDIUM OF MICROSCOPICAL TECHNOLOGY. A Guide to Physicians and Students in the Use of the Microscope and in the Preparation of Histological and Pathological Specimens. By CARL SEILER, M.D., Late Director of the Microscopical and Biological Section of the Academy of Natural Sciences of Philadelphia, Curator of the Pathological Society, Pathologist and Microscopist to the Presbyterian Hospital, etc., etc. Pp. 130. Philadelphia, D. G. Brinton, 1881.

The author has not given us what his preface leads us to expect,—viz., "a comprehensive treatise on the subject." The matter found in his pages is very good, although it falls short of being complete. Written instructions without demonstration probably will never lead to success in mounting microscopic

specimens, and, whilst the methods here recommended are excellent in themselves, each one is not sufficiently described, nor are they varied enough to form a guide to students.

There are many—too many—incomplete manuals like the present one in existence, and it is only the production of an especially good one that can give excuse for presenting another to the public. The hand-book that is wanted in this department of work is one in which the methods applicable to every organ and tissue in their normal as well as their varied pathological states are thoroughly given. The microscope is one and invariable, and has been described over and over again; microtomes and knives are bought of the dealers, and scarcely any one, and especially not a beginner, makes his own reagents. All these things should be omitted. The coming new book on this subject should tell how to handle every specimen from the time it is taken from the body until it is on the microscope ready for examination. The causes of errors in manipulation should be as clearly stated as the method of procedure. We know of no one more capable than the author, with his ample experience, of giving us such a book.

The letter-press and illustrations are good. We note some *unusually* spelled and incorrectly used words. The book is more than worth its price to microscopists, in order to become familiar with Dr. Seiler's mode of work, which has won for him so good a name as a *préparateur*. M. L.

Diseases of Children. By William Henry Day, M.D. Second Edition. Philadelphia, Presley Blakiston, 1881.

A careful examination of this book leads us to characterize it as a plain, straightforward treatise upon the subject of which it treats, well written (except in some rare places), giving sound practical advice, and capable of fulfilling its mission in the world. On the other hand, it seems to us to contain nothing very novel, either in fact or in the statement of the fact; so that it will not supersede the older treatises, but perhaps divide the markets with them. We have only one fault to find, —namely, that modern therapeutics are not in all cases fairly represented. As examples: no mention is made of the great value of jaborandi in the treatment of acute Bright's diseases; and on page 332, where the treatment of true croup is being discussed, we read, "Tartrated antimony is our sheet-anchor as a medicinal agent, from its certainty in effecting free and speedy vomiting." Few of our readers, we judge, but what would agree with us in thinking this very bad practice. Alum, sulphate of zinc, etc., not the horribly depressing antimony, act best,—at least, on this side of the Atlantic. The book contains about seven hundred and fifty pages of large, clear type, printed on paper of a moderate grade.

GLEANINGS FROM EXCHANGES.

Benzoate of Sodium in the Treatment of Acute Rheumatism.—Dr. David MacEwen (*Brit. Med. Jour.*, vol. i., 1881, p. 336), observing that benzoic acid is closely similar to salicylic acid in chemical composition, and somewhat the same in physiological effects, endeavored to determine whether it, like the latter, possesses anti-rheumatic properties. He publishes notes of five cases in which the remedy was employed in the form of benzoate of sodium. On the first occasion in which he used it, the relief of pain and subsidence of fever were so immediate, and the recovery was so rapid and complete, that he had no hesitation in adopting the same treatment in subsequent cases. The dose was, in the earlier cases, fifteen grains of the salt every three hours; in the later cases, twenty grains every two hours. In all the cases the symptoms passed off in periods varying from three days to a week after the commencement of the medicine; in none did cardiac complications arise in the course of treatment, and Dr. MacEwen thinks the convalescence was more rapid than in cases he had seen treated with salicylate of sodium. Benzoate of sodium possesses this advantage, that it does not give rise to the nausea and depression or the unpleasant head-phenomena which the salicylate frequently produces. It is most conveniently prescribed in the form of a mixture, and it may be given in doses of fifteen to twenty grains every two or three hours. It should also be continued in diminished doses for twenty-four to forty-eight hours after the rheumatic symptoms have disappeared.

Salicylate of Cinchonidia.—Dr. Prosser James (*Brit. Med. Jour.*, vol. i., 1881, p. 428) urges the use of this salt as a very useful tonic and antiperiodic in neuralgia, rheumatism, sciatica, etc. In such cases five grains may be given every two hours, or ten grains may be given at once, and afterwards three or four doses of five grains at intervals of two or three hours. This salicylate is cheaper than that of quinia, and can be procured without difficulty in this country. According to Dr. James, it is incompatible with iron. It is rather insoluble, and therefore the bitter taste is not quickly perceived; it may be given as a powder in wafer-paper or in a pill, or it may be suspended in a liquid, though this is not an agreeable method of taking it. Dr. James prefers to give the remedy in compressed tablets. A patient who suffered acutely with neuralgia of the fifth nerve, which had twice been arrested by gelseminum, took for the third attack two tablets (five grains each?—Ed.), repeating the dose in an hour: this sufficed. Dr. James has also used the remedy in pleurodynia and in the pains of chronic rheumatism. He has not yet tried it in acute rheumatism, but thinks that the substitution of salicylate of quinia

(or cinchonidia) instead of the salt of soda would be an advantage. In chronic cases of neuralgia and rheumatism, and in malaria, the salt will also probably be found useful. As a tonic and stimulant to appetite it may be given for a longer period in doses of two to five grains thrice daily.

THE PROPAGATION OF SYPHILIS BY RAZORS.—M. Desprès (*Brit. Med. Jour.;* from *Jour. des Connaissances Méd.*, Dec. 2, 1880) has lately published two cases in which syphilis appeared to have been communicated through the medium of the razor during the process of shaving. In the first case, a man, aged 54, of steady habits, and with no history of venereal disease, was shaved by a barber on July 11, 1880. The man observed, after being shaved, that he had three small cuts on the chin. On July 25 the patient (who had had no relations with women for ten weeks) noticed a swelling at the site of each of the cuts first noticed after the shaving. On September 1 the patient came under the care of M. Desprès, having been sent to that surgeon as a case of epithelioma. On examination there were found three ulcers on the chin, surrounded by some red and moderately hard callosities. There was a hard gland beneath the jaw, but none elsewhere. No other signs of syphilis were discovered at that time. On September 15 a papular syphiloderm appeared. The second case, that of a young man, aged 22, was in many respects similar to the preceding. In him also the initial lesion appeared on the chin, but the patient did not remember having been cut by the razor. In due time glandular enlargement and a general syphiloderm appeared.

A NEW METHOD OF APPLYING NITRIC ACID AS A CAUSTIC.—Dr. Speirs (*Practitioner*, April, 1881), having occasion to destroy a nævus the size of a hazel-nut, situated on the left cheek, under and encroaching on the lower eyelid in an infant, employed nitric acid by the following method:

Taking a two-ounce wide-mouthed vial, he broke off the body close to the neck, inverted the latter over the nævus, pressing the rim of glass firmly down upon the skin. This had the effect of forcing the tumor well up into the neck of the vial; and when the acid was applied by means of a pipette, it acted freely upon the whole surface of the nævus. Before removing the vial-neck, Dr. Speirs carefully mopped out all excess of acid with some cotton-wool on a probe. He then had the satisfaction of seeing a well-defined, circular slough, rather depressed, but with clean-cut edges, as if a punch had been used. The child suffered very little pain, and was easily pacified by being put to the breast. The action of the acid was found to have been entirely confined to the tumor, which was completely obliterated. No cicatricial contraction of the eyelid ensued, and the operation was completely successful.

URIC ACID AND GOUT.—Austin Meldon (*Brit. Med. Jour.*, vol. i., 1881, p. 446) maintains the following theses: 1. The presence of uric acid in the blood is not the sole cause of gout. 2. Want of exercise and of animal diet will produce an accumulation of uric acid in the blood. 3. Uric acid and soda must exist in the blood before the disease can be produced. 4. There must be depression of the nervous system to cause an attack of gout. 5. Depression of the nervous system causes a union between uric acid and soda, forming urate of soda. 6. When an attack of gout has passed away it does not necessarily follow that the uric acid has disappeared from the blood. 7. Uric acid may exist in the blood in considerable quantities and for any length of time without causing gout. 8. The use of nerve-tonics, as quinine, strychnia, and caffeine, and such like, as well as the inhaling of oxygen and the use of electricity, are of much service in the treatment of the disease.

TUPELO TENTS FOR DILATING THE UTERUS.—Dr. Landau (*Med. Times and Gaz.*, vol. i., 1881, p. 327; from *Volkmann's Samml. Klin. Vorträg.*), in a lecture on methods of dilating the cervix uteri, strongly recommends the tupelo tent, made from the root and stem of the *Nyssa aquatica*. He says these tents expand more uniformly than laminaria tents, and their coefficient of expansion is somewhat greater than that of any other tent. In expanding they produce the same softening and infiltration of the uterine tissues as other tents. They do not tend to septic infection; and therefore antiseptic precautions need not be rigidly carried out where they are used. One tent may be kept in three or four hours, and then replaced by another. The cavity of the uterus may thus be made accessible to the finger within twenty-four hours. In two years' use, Dr. Landau has seen no ill effects from their employment.

TREATMENT OF LEUCORRHŒA IN CHILDREN.—Leucorrhœa in children, says M. Bouchut (*Practitioner;* from *Le Praticien*), is caused by vulvitis, not vaginitis or metritis. He therefore treats this condition by extreme cleanliness, repeated bathing with bran-water and lead-water, lotions of corrosive sublimate (two grains to ten ounces of water), carbolic acid (two grains to the ounce), and occasionally solution of nitrate of silver (three grains to the ounce). In the intervals of applying the lotions a pledget of lint saturated with coal-tar or an ointment of red precipitate may be placed between the labia. Such a pledget kept in place by a pad protects the surrounding parts as well as the labia themselves from the irritating secretion, which is often present in considerable quantities. For the general treatment M. Bouchut recommends the administration of cod-liver oil and quinine to strumous patients, and of arsenic to those with eczematous eruptions.

LEAD-POISONING FROM THE USE OF COSMETICS.—At the recent meeting of the Kentucky State Medical Society (*New York Med. Record*, vol. i., 1881, p. 525) Dr. Holland called attention to the fact that there are certain distinctive, though rather vague, symptoms of lead-poisoning which precede the more marked symptoms of wrist-drop, colic, and lead-line, and which, when more carefully studied, would suffice to lead to an earlier diagnosis. These symptoms he described as headache, vertigo, slight colicky pains, and constipation. He then gave notes of the case of a woman who, two years ago, began the use of flake-white powder as a cosmetic. After exhibiting the symptoms already mentioned, she had an attack of melancholia of a month's duration; afterwards, the signs of plumbism—double wrist-drop and the blue line on the gums—were abruptly presented. He related in detail several similar cases illustrating the essential points deduced from the paper,—that lead may be introduced into the system to the extent of its toxic effects when applied on the skin in the form of powder and lotions; that the most popular beautifying cosmetics contain lead. The results of the chemical analysis of various popular cosmetics were given in detail.

SYPHILIS AND LOCOMOTOR ATAXIA.—In a recent number of the *Centralblatt für Med. Wissen.* (*Lancet*, vol. i., 1881, p. 592) Erb has published an additional series of facts confirmatory of those previously brought forward by himself as well as those of Dr. Gowers. Of one hundred consecutive cases of tabes, only twelve gave no history of a chancre or of secondary symptoms. The interval between the primary sore and the first symptoms of the ataxia was ascertained in eighty-eight cases; it was between three and five years in seventeen cases, between six and ten years in thirty-seven cases, between eleven and twenty years in twenty-four cases, and more than twenty years in ten cases. In order to ascertain the truth of the objection that the large percentage of cases of ataxia with preceding venereal sores or of constitutional syphilis is due simply to the commonness of the latter, Erb has investigated the history of four hundred individuals over twenty-five years of age, who were under treatment for diseases which were not suspected to have any relation to syphilis. Only twenty-three per cent. of these gave a history of syphilis, while the percentage of ataxic individuals giving a history of syphilis was eighty-eight! Erb thinks this justifies the conclusion that there must be an etiological connection between syphilis and locomotor ataxia.

SOME NEW USES OF SALICYLIC ACID.—Dr. George Kemp (*Brit. Med. Jour.*, vol. i., 1881, p. 510) says that salicylic acid may be used beneficially as a counter-irritant in superficial rheumatism. Thirty grains of the acid in an ounce of any suitable unguent has been found to alleviate local pain to a remarkable degree. Its advantage is greatly enhanced by the addition of iodide of potassium in an equal quantity. Another use of the remedy is in the form of enema. A case of obstinate dyspepsia with fermentation, only relieved by emetics, and accompanied by constipation and scybala, was treated by enema, with thirty grains of salicylic acid and half an ounce of tartrate of potash dissolved in a pint and a half of lukewarm water. The result was remarkable; the colon was not only relieved of its scybala, but its tonicity was greatly restored, suitable general treatment being resorted to at the same time.

VARIOUS FORMS OF IRON SUITABLE IN THE ANÆMIA OF CHILDREN.—Dr. Jacobi (*New York Med. Record*, 1881, p. 76) recommends in the anæmia of children the lactate (adult dose 1 to 2 grains, soluble in 48 parts water), the tincture of the malate, the tincture of the chloride, the pyro-phosphate (adult dose 2 to 5 grains, soluble in 1 to 2 parts water), and the subcarbonate (dose 5 grains and upwards, insoluble). The syrup of the iodide is called for when an absorbent is wanted. The subcarbonate, combined with three times its weight of subcarbonate of bismuth, and three or four times its weight of bicarbonate of sodium, is especially beneficial when gastric catarrh interferes with general improvement during slow convalescence or progressive anæmia. The tincture of the chloride must be regarded as a vascular irritant; it is the most beneficial preparation where the action of the heart is lowered and blood-pressure is lacking.

MR. SPENCER WELLS'S THOUSANDTH OVARIOTOMY.—At a recent meeting of the Royal Medical and Chirurgical Society (*Lancet*, vol. i., 1881, p. 332) Mr. T. Spencer Wells read a paper on "Two Hundred Additional Cases, completing One Thousand Cases of Ovariotomy, with Remarks on Recent Improvements in the Operation." The mortality of the ninth series was 17; of the tenth, 11. Among the 1000 cases, 231 had died and 769 recovered; but the mortality had steadily diminished from 34 in the first hundred to 11 in the last. Since the 888th case all the operations have been in private practice, and all have been done antiseptically, the result being a mortality of 10.6. Mr. Wells discussed the question how far this lessened mortality was due to antiseptic precautions or to other recent improvements in the mode of operating, describing in detail various modifications in each step of the operation.

NATURAL HISTORY OF LEUCODERMA.—Mr. Squire (*Brit. Med. Jour.*, vol. i., 1881, p. 499) gives the case of a patient in whom vitiligo appeared on the backs of the hands at the age of 38, and disappeared again at the end of six years. The course of this disease is rarely recorded.

THE TREATMENT OF SOFT FATTY TUMORS.—Dr. Schwalbe, at the recent congress of German surgeons (*New York Med. Rec.*, vol. i., 1881, p. 528) described a method of treating telangiectases, soft fatty tumors, and even small herniæ, by the injection of a fifteen- to twenty-per-cent. solution of alcohol. By these injections—which in most cases he repeats perhaps twice a week, and for a prolonged period if necessary—he has secured some excellent results. An extensive telangiectasis of the face which had resisted treatment by the Paquelin cautery had been treated by successive alcohol injections, securing a gradual shrinkage and almost entire disappearance of the tumor.

AN OLD TREATMENT OF DYSENTERY REVIVED.—Mr. Henry Colley March (*Med. Times and Gaz.*, vol. i., 1881, p. 319) says that in the ordinary dysentery of adults with some fever, much griping, constant attempts at stool, with tenesmus, the evacuations consisting of bloody and shreddy mucus, without any proper fecal matter, the proper procedure is to give every half-hour half a minum of the liquor hydrargyri bichloridi (B. P.). The first dose will sometimes relieve the pain; in a few hours the tenesmus ceases, and on the second or third day healthy stools make their appearance. Mr. March looks upon the remedy as the perfection of medication as a specific tonic.

ACUTE ARTICULAR RHEUMATISM OCCURRING IN A CHILD NINE MONTHS OF AGE.—Rheumatism is so rare in the earlier years of life as to be hardly even mentioned by such writers as West and Vogel. Dr. Garden gives (*Practitioner*, March, 1881) the case of an infant of nine months who caught cold from bathing in cold water. Rheumatism followed, affecting the knee- and ankle-joints. These were wrapped in cotton and three grains of salicin thrice daily were prescribed. The patient recovered in a fortnight without showing any signs of heart-complication.

CHRYSOPHANIC ACID IN PSORIASIS.—A correspondent of the *Lancet* (vol. i., 1881, p. 524) says that Prof. Charteris has described in his lectures some cases in which it was very evident that chrysophanic acid acted constitutionally as well as locally. In one very severe case, he, having previously very carefully wrapped up the arm and leg of one side in cotton-wool, applied chrysophanic acid (one drachm to an ounce) to the leg of the opposite side. In ten days the cure was complete, and on removing the cotton-wool from the other side it also was found to be quite cured of the psoriasis. This shows that the drug acts constitutionally as well as locally (?—ED.).

PALATABLE COD-LIVER OIL.—Mr. Fairthorne, the well-known pharmaceutist of West Philadelphia, suggests (*Pharmaceutical Journal*) a new method of administering cod-liver oil, which consists in adding two drachms of tomato- or walnut-catsup to each ounce of the oil, the mixture being shaken before taken. Mr. Fairthorne also states that the following mixture is readily taken by the patient: Liebig's extract, one-half ounce; extract of celery-seed, half a fluidrachm; vinegar, one fluidounce; water, two fluidounces; cod-liver oil, five ounces. The extract of beef is dissolved in the water, the vinegar and oil are added, and the whole shaken with the extract of celery.

ALOPECIA FROM NERVOUS SHOCK.—Dr. Thomas H. Kinney (*Virginia Med. Monthly*, 1881, p. 937) gives the case of a man of 35, who was driving along the road in his cart one day last summer when the lightning struck a tree very near him. His mule was knocked down, and he himself was rendered insensible. He thought he was unconscious twenty or thirty minutes. With the exception of a dazed feeling about the head, which lasted for twenty-four hours, his health was apparently unaffected.

Six or eight days after the shock, the hair on the scalp, face, axillæ, genitals, etc., began to come out, and in a few days he was as hairless and smooth-skinned as an onion.

The after-history of the case is not given.

DESTRUCTION OF TRICHINÆ.—Recent investigations of Dr. Vacher, of Paris, go to show that boiling does not necessarily render trichinosed meat innocuous. He took a leg of pork of moderate size and boiled it thoroughly. A thermometer placed within it at a depth of two inches and a half registered, after half an hour's boiling, 86° Fahr., after boiling for an hour 118°, after an hour and a half 149°, and after two hours and a half, when the joint was thoroughly cooked, 165°. This temperature, M. Vacher maintains, is insufficient to kill the encapsuled trichinæ.

IN ANOREXIA.—M. Huchard recommends the following stomachic for persons who suffer from debility with loss of appetite:

℞ Tinct. cardamomi comp., f℥i;
Tinct. anisi, f℥i;
Tinct. aurantii corticis,
Tinct. gentianæ,
Aquæ menth. pip., āā, f℥iiss;
Aquæ ad f℥i. M.

Sig.—Teaspoonful between meals.

FORTUNATE PROGRESS OF PROFESSOR BILLROTH'S CASE OF EXCISION OF THE PYLORUS.—Professor Billroth's famous case of excision of the pylorus with part of the small intestine lately reported continues to make good progress. The patient has been able to take not only a milk diet, but also, lately, white meats, and has lately left the hospital convalescent.

DR. JACOBI says that strychnia in his hands has proved a valuable adjuvant to iron or arsenic in the treatment of the anæmia of children. To a child two years old it may be given with safety in doses of one-fortieth of a grain daily (in three doses?—ED.), and continued for a long time.

COD-LIVER OIL AND IODOFORM.—Dr. Fonssagrives (*Med. Times and Gaz.*, vol. i., 1881, p. 377; from *Union Méd.*) recommends the following formula: Pale cod-liver oil, 3 ounces; iodoform, 4 grains; essence of anise, 4 drops. The addition of the iodoform and anise masks greatly the taste and smell of the oil, while in every tablespoonful there is one-sixth of a grain of metallic iodine. Persons taking the ordinary cod-liver oil should add a small quantity of table-salt, which greatly modifies its unpleasant taste and facilitates digestion.

MISCELLANY.

CAN A MAN GRADUATE WITHOUT SEEING A CASE?—In New York, apparently, he can. Dr. R. F. Weir, in a letter to the *New York Medical Record*, says that he can say, from personal knowledge, that "a student may graduate without ever having dissected any part of the human body, without ever witnessing or attending a midwifery case, or without ever being present at a hospital clinic." It is also possible for a student "to graduate in less than a year from the beginning of his actual study."

FATAL RESULT OF APPLICATIONS OF PERCHLORIDE OF IRON BY A PHARMACEUTIST.—At a recent meeting of the Anatomical Society of Paris, Dr. Galliard related the case of a man suffering from epistaxis who had been cared for by a druggist. The druggist had tamponned the nasal passages repeatedly during several days with perchloride of iron solution. Death supervened, and at the autopsy gangrenous inflammation of the upper air-passages was observed, with iron-stains, extending through the cribriform plate of the ethmoid to the arachnoid membrane.

REMARKABLE CASE OF EARLY MATERNITY.—Mr. Henry Dodd, of Rillington, York, gives (*Lancet*, vol. i., 1881, p. 601) the account of a joiner's wife delivered, August 8, 1871, of a female child who began to menstruate at twelve months, at first irregularly, but after the seventh year regularly every three weeks. The child ceased to menstruate on June 22, 1880, having been impregnated when eight years and ten months old, and was delivered, at full term, of a child weighing seven pounds. There was nothing remarkable about the appearance of the child, but the hirsute growth over the pubes and in the axillæ was profuse, the breasts large and, at the time of report, gorged with milk.

NEW EXPERIMENTS IN THE ARTIFICIAL PRODUCTION OF TUBERCULOSIS.—M. Hippolite Martin has presented to the Biological Society of Paris specimens of artificially-excited tuberculosis in rabbits resulting from the injection of apparently inert powders (lycopodium, etc.) into the peritoneal cavity.

THE Northern Medical Society of this city has elected two women physicians to the honors of membership.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM MAY 15 TO MAY 28, 1881.

KEENEY, C. C., LIEUTENANT-COLONEL AND SURGEON.—When relieved by Surgeon Baily, to await orders at San Francisco, Cal. S. O. 112, c. s., A. G. O.

BAILY, E. I., LIEUTENANT-COLONEL AND SURGEON.—To report in person to the Commanding General, Military Division of the Pacific and Department of California, for assignment to duty as Medical Director of the Department of California, relieving Surgeon Keeney. S. O. 112, A. G. O., May 16, 1881.

MCPARLIN, T. A., LIEUTENANT-COLONEL AND ASSISTANT MEDICAL PURVEYOR.—When relieved by Surgeon Clements, to proceed to San Francisco, Cal., and assume charge of the Medical Purveying Department in that city, relieving Captain Henry Johnson, Medical Storekeeper. S. O. 112, c. s., A. G. O.

CLEMENTS, B. A., MAJOR AND SURGEON.—To be relieved from duty at Willet's Point, N.Y., June 1, 1881, to proceed to New York City, and assume the duties of Attending Surgeon there, relieving Lieutenant-Colonel McParlin. S. O. 112, c. s., A. G. O.

BACHE, D., MAJOR AND SURGEON.—His leave for one month on account of sickness extended one month. S. O. 79, Division of the Pacific and Department of California, May 17, 1881.

BILLINGS, J. S., MAJOR AND SURGEON.—To proceed to London, England, as a delegate to the International Medical Congress to meet there August next. He will also visit, on public service, such points in Holland, Belgium, Germany, and elsewhere, as may be deemed necessary by the Surgeon-General of the army. S. O. 110, A. G. O., May 13, 1881.

TREMAINE, W. S., CAPTAIN AND ASSISTANT-SURGEON.—His leave of absence on account of sickness, granted him January 20, 1880, from this office, further extended six months on Surgeon's certificate of disability. S. O. 112, A. G. O., May 16, 1881.

MEACHAM, F., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Fort Hamilton, and assigned to duty as Post-Surgeon, Fort Wadsworth, New York Harbor, relieving Assistant-Surgeon Burton. S. O. 90, Department of the East, May 20, 1881.

PATZKI, J. H., CAPTAIN AND ASSISTANT-SURGEON.—When relieved by Assistant-Surgeon Cuningham, to proceed to St. Augustine, Fla., and relieve Assistant-Surgeon Gardner from duty as Post-Surgeon. S. O. 45, c. s., Department of the South.

WOODRUFF, E., CAPTAIN AND ASSISTANT-SURGEON (now awaiting orders in New York City).—To report to Commanding Officer, Willet's Point, N.Y., to relieve Surgeon Clements. S. O. 116, A. G. O., May 21, 1881.

WORTHINGTON, J. C., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort Wayne, Mich. S. O. 86, Department of the East, May 14, 1881.

SHANNON, WILLIAM C., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty at Fort D. A. Russell, Wyoming. S. O. 44, Department of the Platte, May 21, 1881.

CUNINGHAM, T. A., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to duty at Jackson Barracks, La. S. O. 45, Department of the South, May 14, 1881.

BURTON, H. G., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to temporary duty at Fort Hamilton, New York Harbor. S. O. 90, Department of the East, May 20, 1881.

BRECHEMIN, L., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Relieved from duty at Fort Meade, D.T., and assigned to duty at Fort Yates, D.T. S. O. 84, Department of Dakota, May 10, 1881.

PHILADELPHIA, JUNE 18, 1881.

ORIGINAL COMMUNICATIONS.

AN ACCOUNT OF FOUR CASES OF PERNICIOUS MALARIAL FEVER.

BY LOUIS STARR, M.D.,
Physician to the Episcopal Hospital, Philadelphia.

MALARIAL fever may endanger life when it occurs in the very old or very young, and in those enfeebled by disease or other causes; but the term *pernicious* should be restricted to instances in which the symptoms are severe and the paroxysms are prolonged, or in which the effect of the poison falls with special and dangerous violence on a particular organ.

The comatose, the algid, and the hemorrhagic are the chief forms of pernicious fever; other and minor forms are the delirious, the choleraic, the eclamptic, the tetanic, the pneumonic, and so on, an almost endless variety of names being bestowed according to the symptoms most prominently developed.

A number of cases of malaria, of different degrees of severity, were admitted to the medical wards of the Episcopal Hospital during my last term of service, and among them were four examples of pernicious fever. These are worthy of record as well for their intrinsic interest as on account of the comparative rarity of this type of fever in our climate.* I will detail the cases in the order in which they were presented, the histories being compiled from the ward-notes of my resident, Dr. Charles M. Seltzer.

Case I.—Peter ——, æt. 23, by trade a blacksmith, but for several months employed as a hand on a canal-boat, was brought to the hospital at noon on October 11, 1880. The only information obtainable was that he had complained of irregular chills for a few days before, that he had been unable to work on the day preceding, and that on the morning of the 11th he was found in his bunk in an unconscious condition.

On admission, there was profound coma, the skin and conjunctivæ were slightly yellow, the lips and extremities were blue, the surface felt cool, the power of deglutition was suspended, there was bilious vomiting, a tendency to rigidity and convulsive movements of the limbs, and retention of urine. The spleen was greatly increased in size. The respiration was rather labored, and the pulse feeble. A specimen of the urine, removed by a catheter, was found to be unaltered in composition. Sinapisms were applied to the nape of the neck and to the extremities, four grains of sulphate of quinia were injected hypodermically, and nutritious and stimulating enemata were administered. During the afternoon there was a trifling reaction, but there was no return of consciousness, and death occurred before midnight.

At the *autopsy* the spleen was found to be almost black in color, and greatly enlarged, approaching very nearly in size the right lobe of the liver. The liver itself and the cortical portion of the brain were bronzed, the veins and sinuses of the latter were engorged with blood, and there was noticeable sub-arachnoid effusion over the convexity of the cerebrum. The other organs of the body were healthy.

After excluding injury to the skull, and the probability of opium- or alcohol-poisoning, the question to be decided was whether this man was suffering from apoplectic coma due to cerebral hemorrhage or embolism, from uræmic coma, or from the comatose form of pernicious malarial fever. His age and occupation, the history of irregular ague paroxysms, the slight jaundice of the skin and conjunctivæ, the cyanosis of the lips and extremities, the coolness of the surface, the bilious vomiting, and, most of all, the enlargement of the spleen, pointed directly to malarial poisoning. At the same time, the absence of paralysis and organic lesion of the heart and blood-vessels opposed the theory of apoplexy suggested by the deep coma and labored breathing, and the unaltered composition of the urine, that of uræmia, suggested by the convulsive movements of the limbs.

The coma in pernicious fever is usually not so profound as it was here, for ordinarily patients can be roused to answer questions in peevish monosyllables, and low murmurs of complaint, indicating, perhaps, severe headache, may often be heard. This difference, though, was one merely of degree, and may be attributed to the well-defined cerebral lesions observed at the post-mortem examination. The dark color of the cortical portion of the brain, and of the liver and spleen, together with the great enlargement of the latter organ, while confirming the diagnosis, indicated that the paludal influence had been active for a

* Of 780 cases of malaria treated in the Episcopal Hospital during the last ten years, my four cases are the only instances of pernicious fever recorded.

much longer time than might be inferred from the notes.

The record of the next patient's illness illustrates a different and in some respects anomalous train of symptoms.

Case II.—Wm. ——, a laborer, 24 years old, was brought to the hospital on the morning of November 10, 1880. The police-officer who had him in charge stated that he had found him in a semi-unconscious condition upon a vacant lot near the hospital, lying by a cart in which he had been hauling ashes. Afterwards it was ascertained that for a week or more he had had irregular attacks of chills, fever, and sweating.

When admitted, there was great hebetude, questions having to be repeated several times, and being responded to slowly and only in monosyllables. His face was expressionless, and, together with the hands and feet, cyanosed. The conjunctivæ were yellowish and somewhat injected. The extremities felt cold, though the axillary temperature was 103° F. The skin of the trunk and thighs was thickly covered with small, dusky-red, petechial spots. His hands were tremulous, and there was general hyperæsthesia. His tongue was coated; there was obstinate vomiting of bile-stained mucus; the belly was unaltered in shape, and there was no very decided enlargement of the spleen. The cardiac sounds were feeble, and the pulse counted 124; the respiration was irregular and somewhat labored, and bronchial râles were heard over the posterior portions of both lungs. There was retention of the urine, but this fluid was normal in composition.

The patient was at once put to bed, the lower bowel was emptied by an enema, two grains of sulphate of quinia and fifteen minims of dilute muriatic acid were administered every three hours, with a diet of milk and beef-tea, and eighteen fluidounces of milk-punch (one fluidounce of whisky to two of milk), in divided doses.

The vomiting recurred at intervals throughout the day, and as evening approached there was slight muttering delirium; the temperature at 6 P.M. was 99°, the pulse 140. During the night there was considerable restlessness and delirium.

On the morning of November 11 the temperature was 98°, the pulse 132; in the evening the temperature was 102° and the pulse 120. From this date until November 17 the fever presented a decidedly remittent type; the nervous symptoms continued, although they became less marked day by day; there was also diarrhœa, and a troublesome cough, attended with a free expectoration of mucus, occasionally streaked with blood. The vomiting, on the contrary, stopped, the petechial eruption faded, and there was a gradual improvement in the appetite and strength. At 8 A.M. on the 17th the temperature was 96.5° and the pulse 76; subsequently the temperature rose to the normal line, and convalescence proceeded uninterruptedly. The amount of quinia and of milk-punch was slowly reduced, and the diet increased.

The patient was discharged on December 13, 1880.

Here the pernicious paroxysm was preceded by an irregular intermittent fever and followed by a fever which was unmistakably remittent in character.

At first sight the symptoms closely resembled those of typhus fever; thus, there was great hebetude, injection of the conjunctivæ, tremulousness, and hyperæsthesia, a petechial eruption, a high temperature, and a feeble, frequent pulse; on account, however, of the obstinate vomiting, the slight jaundice, and the cyanosis and coolness of the extremities, a positive diagnosis was not made. This reservation proved to be fortunate, as the malarial nature of the disease became apparent after the history was obtained and the range of temperature observed for forty-eight hours.

I have never noted petechial spots in any other case of malaria, and can only explain their existence in this one by supposing them to have been an anomalous manifestation of an inclination towards that form of the disease which is termed *hemorrhagic malarial fever*, and which usually manifests itself by hæmaturia, or by bleeding from the mucous membrane of the stomach, intestinal canal, mouth, or nostrils. When reaction began and the blueness of the lips and extremities disappeared, the skin of the hands and arms, as high as the elbows, presented a red coloration. This redness, associated with the petechiæ, brought to mind the "sub-cuticular mottling" of typhus, described by Dr. George Buchanan as "a faint, irregular, dusky-red, fine mottling, as if below the surface of the skin some little distance and seen through a semi-opaque medium." But as there was also some roughness and slight cracking of the epidermis, the condition was referred to the irritation produced by fine particles of the ashes in which he had been working for some time.

Bronchitis, in my experience, is neither a rare nor a dangerous complication of malarial fever. In my cases the bronchial catarrh has always pursued a regular course, and has not been perceptibly influenced by remissions or intermissions in the fever, although one can readily understand the

occurrence of the intermittent bronchitis and pneumonia mentioned by Hertz.*

The next case is an example of the comatose form of pernicious intermittent fever, and resembles Case I., though the result of treatment was different.

Case III.—Wm. ——, æt. 29, entered the hospital early on November 25, 1880. He was a weaver by occupation, was temperate in his habits, and had never had any serious illness. For several years he had worked and resided within a short distance of the hospital. For eight days before admission he had been subject to ordinary paroxysms of quotidian intermittent fever, and during the twenty-four hours immediately preceding had suddenly become unconscious.

When admitted, he was in a state of semi-coma, loud questioning producing merely unintelligible muttering and slight knitting of the forehead. His face, lips, and finger-nails were bluish, while the rest of the surface was pale; there was general hyperæsthesia of the skin, evidenced by the contraction of the brow and low moaning which followed even a light pinch; the forearms and hands were rigidly semi-flexed; the thumbs were locked, and there were occasional convulsive movements of the arms; the pupils were equal. His tongue was dry and brown; it was impossible to induce him to swallow; there was infrequent vomiting of a yellowish liquid, and the bowels were loose. The abdomen was retracted; the liver-dulness was normal in extent, but the area of splenic dulness was considerably increased. The heart-sounds were healthy; sonorous and sibilant rhonchi were audible over both lungs; the pulse was 96 and feeble, the respiration 20 per minute, and the axillary temperature 100.5° F. The urine, removed by a catheter, was non-albuminous. The treatment consisted of three hypodermic injections of four grains of sulphate of quinia, given at intervals of six hours, sinapisms to the calves, and enemata of milk, together with whisky, and of beef-tea, alternately every four hours. The evening temperature was 100°, and the pulse 92.

By the next morning—November 26—there was much improvement; consciousness had to a great extent returned; the hyperæsthesia, the rigidity of the arms, and the cyanosis had nearly disappeared; the tongue was moist, deglutition was performed with little difficulty, and the vomiting and diarrhœa had ceased. Temperature, 99.5°; pulse, 92. The hypodermic injections were discontinued, two grains of sulphate of quinia and fifteen minims of dilute muriatic acid being administered by the mouth every three hours; the nutritious enemata were also substituted by a diet of milk and beef-tea, with six fluidounces of whisky in the form of milk-punch.

* Ziemssen's Cyclopædia, vol. ii. pp. 611, 612.

After this, with the exception of a trifling attack of lumbago, which yielded readily to counter-irritation, convalescence progressed steadily, and the patient was discharged, perfectly recovered, on December 10, 1880.

In the next case, also an instance of *febris comatosa*, the stage of stupor was succeeded by one of violent delirium; in other words, the distinguishing features of two varieties of pernicious fever—the comatose and the delirious—were associated in the same patient.

Case IV.—D. B., æt. 18, a baker, of temperate habits, residing within a few blocks of the hospital, was admitted at 10 A.M. on November 27, 1880. The friend who brought him stated that for several days he had had paroxysms of chills and fever, and that early on the 27th he suddenly became unconscious. When admitted, he was in a condition of stupor. The pupils were equal and rather dilated; the face, hands, and feet were cyanosed; the arms were rigidly semi-flexed; the thumbs drawn down into the palms, and the fingers tightly clinched over them. His tongue was frosted; it was difficult to introduce liquid into the mouth, and impossible to induce him to swallow. The abdomen was natural in shape. The skin, especially of the extremities, felt cool to the hand.

When I first saw him, two hours later, there was less rigidity of the arms, and pressure over the abdomen caused him to frown and groan uneasily. The axillary temperature was 102° F., the pulse 92 and quite strong, and the respiration slow and rather labored. There was some increase in the area of splenic dulness. The heart and lungs were healthy. The urine, removed by a catheter later in the day, was found to be non-albuminous. The treatment comprised sinapisms to the calves, two hypodermic injections of four grains of sulphate of quinia, one at noon and the other at 6 P.M., a simple enema to clear out the rectum, and subsequently enemata of milk and whisky, and of beef-tea.

During the night of the 27th there was some delirium, and on the 28th he became so violent that restraint was necessary. The face became flushed; the rigidity of the arms disappeared. The temperature at both the morning and evening observations was 101°, and the pulse 88. There was still retention of urine. He swallowed a little food, but the quantity was so small that the nutritious enemata were continued at intervals of four hours. Two hypodermic injections of quinia, four grains each, were given.

On the 29th there was considerable improvement, and he swallowed enough milk and beef-tea to warrant the suspension of the nutritious enemata. Upon the next day he was perfectly conscious and rational. He swallowed easily and readily, passed urine

freely, and had a normal temperature and pulse. Twelve grains of quinia were given by the mouth during the day, the diet of milk and beef-tea was continued, and, as the pulse was somewhat feeble, he was ordered milk-punch.

After this, convalescence was rapid, and he was discharged on December 6, 1880.

In the first, third, and fourth cases during the stage of stupor there was rigidity and even convulsive movements of the limbs, an association of symptoms indicating a simultaneous affection of the brain and spinal cord, and a tendency to the eclamptic and tetanic forms of the disease. Such an association, as well as that of delirium and coma in the fourth case, shows, too, that with this, as with many other diseases, it is often impossible to draw a distinct dividing-line between the different varieties. In regard to prognosis, the danger of a fatal termination seems to be proportionate to the development of the nervous symptoms, perhaps the most unfavorable features being decided convulsions and tetanic spasms.

The point of greatest importance in treating pernicious malarial fever is to get the patient as quickly as possible under the influence of quinia. This is most readily accomplished by administering the drug hypodermically, since it must often happen, as it did in three of my cases, that patients are unable to swallow, or that the large dose required when giving the medicine by the mouth is rejected soon after being swallowed, and since cinchonism follows more slowly and less certainly the employment of suppositories of quinia. The objection to the hypodermic method is the danger of producing an abscess or an eschar at the position of injection. Such a result, though common when the necessary solution is effected by either sulphuric acid or muriatic acid, occurs infrequently when the quinia is dissolved by the aid of lactic acid, or even when it is simply suspended in glycerin. In the three cases referred to, and in a number of instances of ordinary malarial fever, and in several of typhoid fever recently treated in my wards, a solution prepared according to the following formula was used:

℞ Quiniæ sulphatis, gr. xx;
Acidi lactici, ℥xx;
Aquæ, ℥lxxx.—M.

Twenty minims of this solution, containing four grains of sulphate of quinia, were injected at once into the subcutaneous tissue of the arm or thigh. After the injection there was often slight redness, swelling, and tenderness about the puncture, but in not a single instance was an abscess or an eschar produced.

Four grains of sulphate of quinia may be taken as the average hypodermic dose for cases which are sufficiently severe to demand this mode of administration. This quantity is equivalent to three or four times as much by the mouth. The injection may be repeated once, twice, or three times in twenty-four hours, according to the urgency of the symptoms.

If the pernicious paroxysm is prolonged and the power of deglutition is lost, the strength must be maintained by nutritious enemata. Under these circumstances, the rectum should first be thoroughly emptied by a large simple enema, and then, at intervals of four hours, from four to eight fluidounces of milk and four fluidounces of beef-tea may be injected alternately. This gives twelve or twenty-four fluidounces of milk and twelve fluidounces of beef-tea per day, and is about as much as the rectum can dispose of. As, however, the quantity of liquid so introduced is small, it is a good plan to inject, three times during the day, half a pint of water. Both the food and water should be warm when injected, and the addition of pepsin and malt to the former probably facilitates its absorption by producing changes analogous to those of digestion. If stimulants are indicated, half a fluidounce or one fluidounce of brandy or whisky may be added to each enema of milk and of water. Any irritability of the rectum may be overcome by the use of tincture of opium, gtt. v or x to each enema, and it will be found that the food is much more readily retained and disposed of if the large simple enema is repeated once daily to clear away any material that may have escaped absorption. The act of injection should be performed slowly, and afterwards a warm flannel cloth should be held to and pressed lightly against the anus for a few moments.

Revulsion by sinapisms applied to the nape of the neck and to the calves is of great service in aiding to bring about reaction in malarial coma.

After the pernicious paroxysm is broken the plan of treatment does not differ from that followed in malarial fevers generally.

SYMPTOMS (REFLEX) IN AND ABOUT THE EYE, DUE TO SOME AFFECTION OF THE UTERUS OR ITS APPENDAGES.

Read before the Philadelphia County Medical Society, March 10, 1881,

BY WILLIAM S. LITTLE, A.M., M.D.,

Chief of the Eye Clinic, Jefferson Medical College Hospital.

THE physician whose practice is confined to the affections of one organ or set of organs of the body occasionally discovers a class of cases apparently claiming attention to that organ alone; yet an investigation reveals no lesion, but only reflex symptoms existing, due to disease in some organ proximal or distal, and treatment should either by himself or a proper authority be applied to the source of trouble, so as to obtain special and general relief.

The restriction of one's practice should be the outgrowth of well-founded study of general medicine and surgery, both theoretically and practically. Desire may make a specialist; necessity should always claim his general capabilities.

The ophthalmologist comes across persons who seek relief from eye-trouble or are referred for treatment of supposed eye-disease, yet no lesion is found; or, if treatment is applied for the disease of the eye to which such symptoms belong, no relief ensues. A variety of diseases of the eye present common symptoms; but in this class of cases, finding another organ at fault, treatment of this not only relieves the eye, but a general improvement results.

Reference is made to cases where only eye-symptoms are present and the inference is natural that the eye is at fault, the patient complaining of nothing else, and no available symptoms being present to make the physician think otherwise.

Students should be taught that the eye is part of the body, presenting anatomical conditions, mechanical action, and tissues found elsewhere in the body; and that proximal and distal organs, when in health, have a sympathetic union with the eye; and, when diseased, have secondary, if not primary, lesions in the eye, or produce sympathetic conditions which point to this organ. Knowledge of the anatomy of the eye, combined with as much common sense as is exhibited in treatment of organs whose anatomy is compelled to be known, would relieve the term of specialism from ophthalmic practice as far as therapeutics and surgery go, the optico-medical and surgical condition excepted.

The sympathetic symptoms and inflammatory processes occurring in the eye in connection with brain-lesion, kidney-affection, syphilis, and rheumatism, are fully known to you. Not sufficient attention has been called to the presence of symptoms in and about the eye associated with affections of the uterus and its appendages.

Clinical observation reveals the proneness of the eye to exhibit alone, symptoms that refer to disease of another organ or set of organs, these diseases not being suspected or symptoms existing to point to them; while, on the other hand, this organ or set of organs being known to be at fault by prominent symptoms, the eye is free from any connection either by sympathetic symptoms or diseased condition, or, if affected in either way, is less prominently so.

To illustrate: in morbus Brightii, more cases will be referred to the practitioner of medicine by the ophthalmologist, which come to him with eye-trouble, due to changes in nerve and retina, from morbus Brightii, than he will find eye-symptoms in cases known to have kidney-affection and sent to him by the practitioner of medicine for additional evidence to be found in the eye. The same may be said of diabetes. Even syphilis manifests itself in this way, and cases of choked disk due to intracranial causes apply for eye-treatment more frequently than one finds choked disk in connection with known brain-lesion. So also with rheumatism. I desire to add the capability of the eye alone, or parts about it, presenting symptoms associated with diseases affecting the uterus and its appendages.

Here let me state that the normal-tissued, perfect-sighted (emmetropic) eye is more free from disease and more readily cured than the abnormal-tissued, imperfect-sighted (ametropic) eye; and this holds for reflex symptoms as well as when the organ alone is at fault or the two conditions combined; the percentage of emmetropic eyes being so low makes the assertion more worthy of advocacy.

The following cases exhibit the practical bearing of my remarks, though I can give no connection between the two organs but the broad base of reflex action through the sympathetic system.

All these cases presented themselves at the Jefferson Medical College Hospital, and were observed and treated by Prof. J. M. Da Costa, of the medical clinic, Prof. Wallace and Dr. Getchell, of the gynæcological clinic, Prof. Wm. Thomson and myself, of the ophthalmic clinic.

I am indebted to Dr. J. W. Barr for the notes stating the gynæcological condition and treatment.

Case I.—Miss C., æt. 18. Seen January 24, 1878. Sent by a physician for treatment of eyes; was led into the room, eyes protected from light; severe headache for long time, unable to work on account of inability to use eyes; worse at menstrual period; hysterical at times. Found photophobia, blepharo-spasm, lachrymation affecting both eyes, hyperæsthesia over infra- and supra-orbital region both sides and anterior fontanel, great pain on pressure; in fact, the same was general over the whole body. Hearing was modified: right ear, watch at 2 inches, left ear at 8 inches.

Vision, on account of great irritation from light, was R. E. V $= \frac{10}{C}$,

L. E. V $= \frac{15}{C}$.

Field of vision at two feet—

R. E., 8 inches circular;
L. E., 6 " "

From the severity of the symptoms, I was led to think that the nerve and retina were implicated, perhaps with meningitis. The ophthalmoscopic examination was difficult at first visit, but revealed hypermetropia, optic nerve slightly red, but no change in retina. It was considered an eye-case: ordered leeches to the temples, iodide of potassium, and hydrarg. bichlor.

January 27.—Symptoms better; R. E. V $= \frac{20}{LXX}$, L. E. V $= \frac{20}{LXX}$; hyperæsthesia still present.

February 2.—R. E. V $= \frac{20}{XL}$,

L. E. V $= \frac{20}{XL}$; gave strychnia $\frac{1}{20}$ gr. t. d.

February 28.—Slight general improvement.

March 10.—Not so well.

March 12.—Atropia for blepharo-spasm.

March 24.—Blepharo-spasm still present; less photophobia.

April 8.—Continues the same; gave bromide of potassium.

April 24.—Field of vision at two feet—

R. E., 14½ inches circular;
L. E., 10 " "

May 6.—R. E. V $= \frac{20}{XL} + 1.d = \frac{20}{XX}$;

L. E. V $= \frac{20}{XL} + 1.25d = \frac{20}{XX}$.

The idea of nerve- and retina-trouble was given up early in the case, and, though perfect sight was obtained, all the other symptoms remained.

July 7.—Field of vision still limited; other symptoms about the same; consulted medical department.

July 11.—Sent to gynæcological department,—the notes are presented,—with final relief of eye-symptoms and general improvement of health.

I have heard from this patient recently, and she considers herself well.

Case I.—Gynæcological notes, with treatment. Seen March, 1879. Headache; dyspeptic; menstruated at 15 years, recurring at intervals of one to three months, always scanty and pale, lasting one day. Hysterical spasms at 17 years of age, continued ever since. Not menstruated for two months; occasionally vomited blood. Leucorrhœa; conical os uteri; intense hyperæsthesia of genitals and over abdomen. Vaginitis. Treatment: application of solution of nitrate of silver twice weekly; warm injections twice daily; also leeched. Internally, iron.

Case II.—Miss M., æt. 18. Seen November 2, 1879. Sent from medical clinic for examination of eye-ground and treatment of eye-trouble, which was very severe, she having been treated for epileptoidal attacks, which still continued, with hysterical manifestations in addition. The eye-symptoms and facts about the eye appeared identical with those in Case I., and need no repetition.

R. E. V $= \frac{3}{C}$; L. E. V $= \frac{2}{C}$.

Field of vision at two feet—

R. E., 4 inches by 8 inches;
L. E., 5½ inches by 5 inches.

She remained in hospital for six weeks, receiving the same plan of treatment as Case I. Full vision was obtained, but limitation of field of vision and the other symptoms remained about the same; hysteria and epileptoidal attacks are prevalent. She was referred to the gynæcological department, who treated the condition found and reported in these notes; eye-symptoms were relieved, and general health improved.

Seen February 9, 1881.—No epileptoidal attacks for four months. Gave her correction for her optical defect, having compound hypermetropic astigmatism for both eyes; has no eye-trouble.

Seen March 1, 1881.—One epileptoidal attack, lasting a few minutes, since last seen; otherwise well, and is gaining her livelihood.

Case II.—Gynæcological notes and treatment. Constant headache; pain over left breast and down spine and in lumbo-sacral and inguinal region. Appetite poor; troubled much with flatulency and indigestion. Constant diarrhœa; painful micturition; eruption (acne) over face and chest. Spasm (epileptoidal) frequently. Menses irregular, too frequent, and lasting eight days each period.

Endometritis both cervical and corporeal. Leucorrhœa intense. Conical os uteri.

Treatment: application of Monsel's solution to whole of endometrium twice weekly; warm injections twice daily. Internally, general tonics. The notes do not state, but later Dr. Getchell amputated the os uteri. Case discharged well.

Case III.—Miss —, æt. 32, said to be unmarried, presumed childless. Seen November 14, 1880. Gave history of severe fall on head six years ago; has rheumatism, eruptions on skin, hair coming out for some time. Presented all the symptoms as to the eye and about it as Cases I. and II., only more severe —having existed for the last six weeks. Atropia gave no relief for blepharo-spasm; vision reduced; has hypermetropia, field limited. Gave same treatment for one week. Sent to gynæcological clinic; their notes are presented.

January 28, 1881.—Eye-symptoms almost entirely disappeared; convalescing from treatment; left hospital few days after, not seen since till March 3, 1881. General health better; bears light with colored glass well; less sensitiveness over affected parts. With correction for optical defect, $V = \frac{20}{XX}$; without, $\frac{20}{C}$, due to compound hypermetropic astigmatism. The symptoms have disappeared more slowly than in other cases, but were far more marked, as the uterine conditions were found to be also.

Case III.—Gynæcological notes and treatment. Menstruated at 12 years; menses always irregular, both as to time and quantity. Always complained of headache, and nervous generally. Appetite variable. Pain in lumbo-sacral region and down thighs. Pain over region of womb. Cervix slightly lacerated, result of labor at 21 years. Perineum lacerated extensively. Endometritis both in body and neck. Operated upon by Dr. Getchell in hospital, January 15, 1881, for laceration of perineum. Result, a good perineum, and all symptoms of disorder gradually disappearing. Is well.

No inflammatory processes existed in the eyes of these patients, though if they had existed the same principle would have held, making the cases more complicated, requiring gynæcological and ophthalmic treatment, and no positive relief would have ensued till the uterine disorders were relieved, doing away with the reflex symptoms and enabling the eye-symptoms proper to be handled by themselves. I seek, however, to point out reflex symptoms in and about the eye associated with disease of the uterus or its appendages. The eye-symptoms are not numerous; confined to photophobia, lachrymation, blepharo-spasm, decrease of vision, reduction of field of vision, hyperæsthesia of the infra-orbital and supra-orbital region, region of seventh nerve on face, especially over the exit of these nerves on the face, great sensitiveness over anterior fontanel on pressure. All had hysterical manifestations, and one epileptoidal attack. All these symptoms, separately or conjointly, can occur in diseases of the eye, except hysteria and epilepsy; but in these cases there was no eye-disease, no corneal trouble, no vitreous opacity, no retinitis, no neuritis, the hypermetropia present was not enough to account for all, and its correction gave no benefit except to acuity of vision; atropia did not prevent the blepharo-spasm.

Hypermetropia was present in all the cases, showing that ametropic eyes are more liable to symptoms than emmetropic eyes. Though it could no doubt exist in such eyes, myopic eyes have not been seen by me to present the same symptoms.

The first case was treated for eye-disease with no relief, and I was slow to give up the point; the second case was not benefited by a shorter course of treatment of eye-disease; in the third case I began at the other end of the dilemma, and not only eye-symptoms were relieved, but a more serious difficulty arrested and general relief obtained.

These eyes presented no primary lesion, no secondary disease, only reflex symptoms due to nothing but disease affecting the uterus or its appendages. It might be proper to classify such symptoms under the head of hysteria limited in its manifestations to parts in and about the eye. Such cases are not eye-cases. You may remember such cases in your practice, you may meet them hereafter: exclude eye-disease, and seek for the cause where it belongs.

JABORANDI IN GLAUCOMA.

BY P. D. KEYSER, M.D.,

Surgeon, Wills Eye Hospital, Philadelphia.

OCTOBER 8, 1880, Mr. L., æt. 50, called to consult me in relation to a dimness in his vision that had been coming on for some time.

On examination, I found the lens of the right eye cataractous, and some posterior synechiæ,—which he reports has been so for fifteen years,—while his left eye has remained good all the time up to lately. He had, however, been suffering at times with slight shoots

of pain in the eye and a mist before it, which was thicker at times. He had noticed rainbows and great rays around the flame of the street-lamps, and, at times, in those in a room, especially if the room was very warm. He felt better in the cold air; in a close warm room he could not see. The past few days the cloudiness before the eyes had become more or less permanent.

The vision of the left eye was $\frac{15}{C}$, that of the right was light and passing objects.

He says that he has always been a little near-sighted, for which concave glasses have been worn.

Tension of the left ball was +2.

The field of vision was somewhat reduced in the inner and upper part.

Ophthalmoscopic Examination. — Media clear; optic disk slightly cupped; central vessels very full, but no pulsating artery.

The symptoms of glaucoma being present, I told him the nature of the trouble, and suggested the necessity of operative influence; but, not liking my suggestions, he left, to return the next day more anxious than before about himself, as his vision was more clouded than ever.

On examination now, the fundus of the eye could not be defined, on account of a brown cloud which appeared to be in front of the pupil. By careful illumination, a deep-brown infiltration could be seen in the centre of the cornea over the pupillary region, while the periphery was clear, through which the bluish-gray iris could be plainly perceived.

The tension of the ball had increased to +3.

I now urged the operation, but under no condition would he as yet consent thereto. I then determined to use eserine, but on a second reflection the idea came to me to try the action of jaborandi in its great power on the sudorific and salivary glands in the effect of elimination, knowing that considerable success had been attained by its use in affections of the vitreous, choroid, and detachment of the retina, and that its alkaloid, pilocarpin, locally, had somewhat the effect of eserine. I ordered him to take a teaspoonful (sixty minims) of the fluid extract at bedtime for three nights in succession, after which to see me.

He returned as I requested, and I found the eye very much improved. The tension was reduced to +1; the cornea was perfectly clear, the brown infiltration having entirely disappeared. The jaborandi had caused very profuse sweating, lasting for two full hours every time it was taken, and the salivary flow was very copious. Vision had increased to $\frac{20}{LXX}$. The dimness had passed away, which was naturally to be expected after the reduction of the increased tension and the disappearance of the brown cloud from the cornea.

I still suggested the operation, but no persuasion could get him to consent thereto, he being then satisfied with the improvement.

This is the second case of a brown infiltration in the cornea in glaucoma that I have seen, both of which were absorbed on the reduction of the tension. The first case I reported in the *Philadelphia Medical and Surgical Reporter*, July 18, 1874. Iridectomy was then performed, and complete absorption did not take place until twenty days after the operation. In the above-mentioned case of Mr. L. he was only three days on the use of the jaborandi.

In looking through the literature upon glaucoma, I do not find any mention of this pigmented infiltration in the cornea. Von Graefe first described a sclerous infiltration and a circumscribed rectangular ribbon-form opacity. Shiess-Gemuseus called attention to a uniform cloudiness spreading over the whole of the cornea without any change in the epithelium, as is seen in diffused and interstitial keratitis.

October 19, 1880, I was sent for to see Mrs. E., æt. 55, who was not able to leave her room, having been confined to the house for several weeks from an attack of rheumatism. She had been a sufferer, more or less, for years, from rheumatic gout. She was complaining of great pain in and around the eyes, with considerable inflammation in the left one, when I was sent for.

On examination, I found the tension of both balls increased to +3. In the left eye there was considerable pericorneal injection. The pupils were not dilated more than normal. She remarked that at times she had had great flashing of light and falling stars in the eyes, and sometimes rainbows around the lights, and even sharp shooting pains up in the head from the eyes. These premonitory symptoms of glaucoma, however, did not remain long, passing away and leaving the eyes in their former good condition.

The ophthalmoscopic examination showed the media clear, and that there was no cupping of the optic disks nor pulsating artery. She had never had the same feeling of pain and fulness in the eyes as she then had, which had been continuously for three or four days and nights, preventing sleep.

The success of the jaborandi in the previous case recurring to my mind, it suggested the trial of it again, and a teaspoonful of the fluid extract was given that night. The next day I found that she had had a very profuse sweat, with great flow of saliva, for nearly three hours, after which she slept until seven o'clock in the morning. The pain had all passed away, and the tension was reduced to about +1.

She complained of the taste of the jaborandi so much that the next night a hypodermic injection of one-eighth of a grain of nitrate of pilocarpin in solution was substituted, with the happy effect that the next day

all pain and increased tension of the balls were gone.

December 19, 1880, I was called to see an old gentleman in West Philadelphia, who had been blind for some years, but who was then suffering with great pain in the eyes. I found him blind from absolute glaucoma, both eyes. At times he had had attacks of severe pain, but the intervals had become shorter and the pain more exquisite, and for the past few days it was almost unbearable. To relieve him completely from pain, enucleation was advised, which advice was not accepted at that time: so I ordered him to take the fluid extract of jaborandi that night, and prepare himself for a good sweating and salivation. The next morning I found that he had rested very comfortably after the action of the jaborandi had passed away, and was then much relieved from pain.

It is well known that the premonitory attacks of glaucoma do at times pass away spontaneously, more especially after sleep; also that eserine, the active principle of the physostigma (Calabar) bean, used as a collyrium, has the power of relieving for a time these symptoms. In the first instance, as well as in sleep, the natural relaxation that takes place, with the consequent reduction in the intraocular tension, permitting the proper flow of the stagnated or choked blood from the eye, removes the attacks, while the myotic action of the eserine, contracting the pupil as well as constricting the vascular system of the eye, has the same effect of relieving the tension and diminishing the secretion. Pilocarpin, the active principle of the jaborandi, has the same myotic action on the eye that eserine has, but it does not appear to be strong enough alone in its action to relieve the glaucomatous symptoms as promptly.

Now, if thorough relaxation is one of the necessary things in these cases as well as myosis, the jaborandi internally will naturally be one of the effectual remedies to relieve the tension of the system, and therewith the increased firmness of the eyeball, and thus permit the regular circulation to take place for the time being, thereby removing the symptoms and attacks of glaucoma; but, like eserine, it can only be temporary in its action, and cannot effect a permanent cure. The salts of eserine and pilocarpin are somewhat expensive for the patient, and not always readily to be had at the different druggists', while the fluid extract of jaborandi is now so frequently used that it is to be found at a reasonable price in almost every apothecary's shop in large and small towns.

It is very remarkable that of the eyes lost from disease (not injury) one per cent. is found to be caused by glaucoma, very many of which, as noticed by ophthalmologists, are permitted to go blind for want of knowledge in the physician consulted, to distinguish the premonitory symptoms of this most important and dangerous disease of the eye,—the old story of neuralgia in the eye and head, with occasional dimness of vision, for months or years past, for which quinine, narcotics, etc., *in quantum infinitum aliter ad nauseam*, have been taken, until, finally, the sight is entirely lost, either gradually passing away or by a stormy attack of inflammation.

It is not to be expected, however, that the general practitioner can be so thoroughly learned in ophthalmology as to be able to diagnose correctly all the different diseases of the eye, and especially to perceive the gravity of a glaucomatous affection. It seems natural that the extreme violence of the circumorbital pain and the hemicrania, with but little if any injection or special outward appearances of inflammation, would direct the attention of the physician to neuralgia. But so much has been written in all the medical journals upon the subject of glaucoma during the past ten to twelve years, describing all the peculiar symptoms, with the dangers attending them, that one would suppose the whole profession would be on the alert to notice and diagnose this disease, as well as ready to avert its consequent blindness, knowing full well that the most brilliant triumph in ophthalmology has been gained in the treatment of this affection of the eye.

It is not in all cases that the premonitory symptoms of neuralgic pain—rainbows and flashes of light, etc.—are present, but with a few there are really no symptoms to attract one's attention except a progressive loss of sight. This naturally would mislead the physician not versed in the use of the ophthalmoscope as well as the regulations of the tension of the eyeball; but by careful examination of the field of vision some light may be thrown upon the case, for in such cases a reduction of the field in the upper and inward part is marked, which progresses until the power of vision is limited to directly outward on

the temporal side, and finally is lost altogether.

Eserine and pilocarpin have been found the most efficient remedies as yet to temporarily relieve the painful symptoms of glaucoma until operative influence — the only reliable means of giving permanent relief—is resorted to; but, as before mentioned, these are too expensive and too little used to be found in the stock of drugs of a country practitioner as well as in all the drug-stores of our cities, while the fluid extract of jaborandi is a remedy of frequent use, and inexpensive; so that in every case where suffering from an attack of circumorbital neuralgia with dimness of vision and increased tension of the eyeballs is found it would be well to try it in full doses, and if on the next day or two there be any reduction in the tension, remission of pain, with somewhat clearer vision, it should be the duty of the physician to have the patient consult an ophthalmologist at once for careful examination and treatment, if the sight is to be saved.

1630 Arch Street.

NOTES OF HOSPITAL PRACTICE.

UNIVERSITY HOSPITAL.

CLINIC OF DR. LOUIS A. DUHRING, PROFESSOR OF DISEASES OF THE SKIN.

Reported by Henry Wile.

ACUTE VESICULAR AND PUSTULAR DERMATITIS.

CASE I.—The patient before us is a woman about 30 years of age, and exhibits, as you see, an acute inflammation of the skin. The disease seems to be confined to the left forearm, and is of a marked type, being characterized by pustules and vesico-pustules, varying in size from a pin-head to a split pea, scattered over the surface, the whole forming a diffuse patch over the flexor and extensor surfaces of the forearm. Some of the pustules have run together, forming flat pustular areas; others have ruptured, and have formed crusts. You will notice that there is marked œdema of the forearm, and, coming down upon the backs of the fingers we see altogether about a half-dozen disseminated pustules.

On questioning the patient, we find that the disease is of one year's duration,—that is, the patient has undergone five distinct attacks, this being the fifth. She has had two attacks on the face, one on the right forearm, and one on the left forearm, where the disease is at present located. The patient states that the disease in each attack had always undergone the same development, being characterized by both general and local symptoms. After a high fever the disease manifests itself locally, first by itching, then by pain and a sense of burning, and, finally, by the appearance of red spots, vesicles, pustules, and blebs. The first symptom of the present attack appeared last Saturday (six days ago); thus it has taken nearly a week for the disease to develop into its present condition.

It is very important to get the history of this disease, for without it a positive diagnosis would be difficult, because there are several skin affections which resemble it in external appearances but differ in history and mode of development. The disease, of course, closely resembles eczema, but differs from it in several particulars.

The diagnosis is that of a vesicular and pustular dermatitis of an obscure nature. The treatment, therefore, may be that of any simple inflammation of the skin. We shall give at first a lotion, which is to be followed by an ointment. The following is advised for the first three days:

℞ Ext. grindeliæ robustæ fld., f℥j;
Aquæ, f℥viij.

Sig.—Apply as a lotion three times a day.

After the second or third day we shall order the oxide of zinc ointment to be used.

TINEA FAVOSA.

Case II.—A boy 18 years of age, with tinea favosa, the disease occupying a greater portion of the scalp. He states that he has had it since he was nine years old, and is positive that he contracted the same by "lending his pocket-comb to another little boy who had the same disease on the head." After recognizing the disease, we are able, in most cases, to give the history of its development better than the patient himself.

It begins usually in small areas by the development of small, pin-head-sized, yellow crusts, which form slowly. These crusts are situated around the hair-follicles, and they possess a characteristic sulphur-yellow color; they attain the size of a split pea, are decidedly cup-shaped, and,

when they coalesce, form large patches, which, not being removed, may become several lines thick. By separating the hair of the scalp we notice the peculiar yellow crusts, some confluent, others discrete. During the development of the disease the hair becomes exceedingly dry and brittle. In this case we also note several partly bald patches upon the scalp.

This disease may attack any part of the body, but its favorite seat is the scalp. It is caused by the presence of a vegetable parasite known as *Achorion Schönleinii*, which was discovered by Schönlein, of Berlin, in 1839. The crusts are made up almost entirely of parasitic matter, together with epithelial scales; hence they are very different from the crusts of eczema, with which disease tinea favosa may be confounded.

The disease is contagious, but it does not thrive equally upon all individuals, which is shown by the fact that physicians continually handling cases rarely, if ever, acquire it. It has a characteristic, peculiar, mousy odor, which often alone enables us to make a positive diagnosis. The disease is very rare in private practice, and seldom, if ever, occurs on stout, healthy individuals. It is a disease almost entirely confined to the lower classes, and is mostly found upon the ill-nourished and upon those whose condition of general health is poor.

It is a known fact that the disease may be readily contracted from the lower animals, especially from cats. The following incident may serve as an illustration. A gentleman, while out walking one evening, picked up a little kitten and carried the creature a few paces to his home. The next morning he noticed some crusts on its head, and, fearing something wrong, he destroyed the cat. Ten days later he came to me with two or three small crusts upon the backs of his fingers, and I recognized the disease to be tinea favosa, and, by questioning, gained the above history. I may add, by the way, that it required three months for him to be cured, and I may also state that two servants in his household likewise contracted the disease, also upon the hands, by handling the cat.

The disease is thoroughly curable, yet the prognosis should always be guarded, as some cases get well easily, while in others the disease proves to be very obstinate. Three remedies are necessary,—extreme cleanliness, depilation, and parasiticides. There are a number of parasiticides, any of which may be used. When the virtues of one seem to give out, another should be substituted. The hair of the scalp should first be cut short, and then sapo viridis, with hot water, applied to remove the crusts. The application should be made night and morning until the crusts are removed. In the intervals between the applications cosmoline may be rubbed in to aid in softening the crusts.

After the crusts are removed the hairs should be extracted with forceps. After this operation some parasiticidal preparation—which is the remedy to be relied upon—should be well rubbed in. The following lotions are recommended:

℞ Sodii hyposulphit., ℥j;
Aquæ, f℥j.

Or,

℞ Hydrargyri chloridi corros., gr. j;
Aquæ, f℥j.

Either of these lotions should be freely used, and allowed to remain on for half an hour.

Chrysophanic acid, in the strength of gr. xv–xxx to ℥j, is highly recommended; but it should be used with caution, lest a violent dermatitis be set up, not only of the part treated, but upon the adjoining healthy skin. In a case such as the present, where the disease is of long standing, and extensive, months will be required to effect a cure.

TINEA VERSICOLOR.

We have here, in the case of this young man, another parasitic disease, which is known as tinea versicolor. It is typical in form and in distribution. It is caused by the presence and development of a vegetable parasite called Microsporon Furfur, which gives evidence of its presence by the formation of pin-head, split-pea, and larger-sized patches, of a faint, dirty-yellowish color. These may be discrete or confluent, often covering large areas. The disease in this case is located on the back of the neck, on the shoulders, even extending down on the arm, and on the chest and back. The patches have a smooth appearance and feeling, but, nevertheless, show slight desquamation. The scales are very fine and mealy, being composed of epithelial cells thoroughly filled with the fungus.

The disease yields completely to treatment. The patient will be directed to take a bath daily, using sapo viridis freely, and then to apply a parasiticide to the affected part twice a day. We shall order the same lotion of hyposulphite of sodium as in the case of tinea favosa. A few weeks will probably suffice to cure the disease. The treatment should be continued for several weeks after all signs of the lesions have disappeared.

ECZEMA VESICULOSUM OF THE HANDS.

The patient is a young man who has a vesicular eruption on the back of his hands and on his fingers. The diagnosis lies between scabies and eczema vesiculosum.

The affection here consists of vesicles, pustules, excoriations, and crusts, with but little itching, and with no disposition to spread. The patient says that he has had the disease for one month. It cannot, therefore, be scabies, for in that time the disease would have increased extensively. The disease is eczema vesiculosum. The following ointment will be prescribed:

℞ Hydrargyri chlor. mitis, ℥ss;
Ungt. zinci oxidi benz., ℥j.
Sig.—Apply twice daily.

TRANSLATIONS.

VEGETABLE ASTRINGENTS.—In a lecture on this subject before the Hygienic Society, Dr. Lewin, of Berlin (*Deutsche Med. Wochens.*, 1881, p. 202), says that if there is one therapeutic principle which has seemed firmly established it has been the influence of tannic acid and the substances composing it upon the animal tissues. Dead tissues are known to be hardened and toughened under its influence, and living muscle and skin are believed to undergo similar changes. Reasoning from these facts, it has seemed unquestionable that a similar effect is produced on the vascular walls, so that diminished secretion as well as the cessation of parenchymatous bleeding, with contraction of the blood-vessels, is produced by its influence. Recent researches, however, go to contradict this long-cherished theory. By bringing a solution of tannin in contact with the mesentery of the frog, Rosenstein succeeded in developing—not contraction, as might have been expected, but dilatation. For this reason he is inclined to remove tannin from the class of astringents.

This discovery of Rosenstein's, together with the paucity of facts concerning the action of tannin to be found in the text-books, and the statement therein given that the influence of tannin is a purely local one, led Lewin to enter anew into the examination of the subject. The conclusions of his researches are given in this lecture, as follows:

Tannin coagulates albumen and albuminous substances. The albuminate of tannin thus formed is soluble in an excess of albumen, in lactic acid, in carbonic acid, and in the caustic alkalies. Tannin loses the peculiarity of causing coagulation if it is made slightly alkaline. Pepsin and peptones in solution are precipitated by tannin, but these precipitates are soluble in the hydrochloric acid of the stomach. Thus it is that, as has already been proved, artificial digestion of albumen goes on in a normal manner under the influence of tannin, that no hinderance is offered to the formation of peptones, and that the pepsin present is not precipitated on account of the hydrochloric acid present. It is of course understood that tannin only precipitates the albumen of the blood when it is in sufficient quantity to give an acid reaction to the fluid: the albuminate of tannin thus formed is dissolved again in an excess of alkaline blood.

The possibility of the absorption of tannin is thus explained. Small quantities of tannin are taken up into the lymphatic circulation with the food, and are sent into the blood-circulation as alkaline tannates. Dr. Lewin has succeeded in showing that the tannin thus absorbed is not all metamorphosed, some remaining and being discharged in the urine as tannin. It thus appears that tannin may reach the various parts of the body still preserving its therapeutic qualities. The urinary secretion is diminished under the influence of tannin, and Lewald has shown by quantitative examination that in Bright's disease the quantity of albumen in the urine markedly decreases under the influence of the drug. The widening of the capillaries of the frog's mesentery under the influence of tannin is explained by the occurrence of stasis in the capillaries. The directly-applied tannic acid solution diffuses into the capillaries, causes coagulation there, and, as a result of this, the vessels lying

beyond the affected capillaries experience dilatation from stasis.

As a practical result of his investigations, Dr. Lewin recommends a new form of administering tannin. Experience shows that tannin solution and, still more, powdered tannin not infrequently fail in the desired effect; secondary influences are exerted, which show themselves in irritation of the gastro-intestinal canal, pressure in the epigastrium, loss of appetite, coated tongue, diarrhœa, etc. These evil effects are obviated if the tannin is given in the form of an albuminate. If to a one to two per cent. solution of tannin a filtered solution of an egg in one hundred centimetres of water is added, and the mixture well shaken, an opalescent, light, milky-colored fluid results which has a much less astringent taste than the corresponding tannic acid solution. It may be prescribed thus:

℞ Sol. acid. tannic. (2 per cent.), gr. cl;
Add, shaking,
Sol. albumin. ovi un., gr. c.—M.

This solution gives good results even when much diluted, and may be used in very young children.

Diagnosis between Senile General Paralysis and Senility.—The distinction between general paralysis and apparently similar cases of senile feeble-mindedness is not always easy to make, and the diagnosis cannot be based upon the patient's age. True paralysis may occur at an advanced age, while senility may come on long before the individual has neared the end of life. Drs. Seppi and Riva (*Deutsche Med. Wochens.*, 1881, p. 207, from an Italian source) suggest the following points. 1. The most prominent anatomical characteristics of paralysis are aneurism of the cerebral arteries, hypertrophy of the interstitial connective tissue of the brain, fatty and pigmentary infiltration of the ganglion-cells, and finally diffuse atheroma. The chief distinctive clinical peculiarities are atheromatous pulse and slight severity of the apoplectiform attacks. Lack of tendency to fever, and the absence of those periodic variations of temperature characteristic of the other form of brain-trouble, as well as the progressive loss of the mental faculties, in connection with vague delirium and invalidism, and without any tendency to the *délire des grandeurs*, are all characteristic.

Scrofula and Tuberculosis.—At a recent meeting of the Société des Hôpitaux (*La France Méd.*, 1881, p. 368) Dr. Villemin remarked that formerly the word "scrofula" was employed solely to designate ganglionic tumefactions of the neck, suppurating ganglions, etc. Later, all ganglionic alterations were included under this category, and then superficial changes in the skin and mucous membranes. It may be the case, after a while, that this term may include and serve to designate all those alterations at present termed syphilitic and rachitic, including also "morve" and farcy. Scrofula must, then, be divided—like syphilis—into primitive, secondary, tertiary, quaternary. When it is perceived that we have gone too far, then syphilis and "morve" will be eliminated. M. Villemin cannot admit that tuberculosis and scrofula are one and the same, that tuberculosis is nothing more than a manifestation of scrofula. There are numbers of tuberculous persons who have never presented a sign of scrofula. In fact, the tubercular lesions no more belong to scrofula than do the manifestations of syphilis, which were formerly supposed to be connected with scrofula.

The characteristics of a disease are not more in the lesion than in the cause. The etiological element is the most important. Has not M. Kiener shown that cold abscesses, alterations in the synovials and the bones, are nothing more than tubercular affections? Instead of asserting that patients dying tuberculous were scrofulous previously, why not assert that, being tuberculous, they have succumbed to an extension of the affection? M. Villemin does not believe in the existence of scrofula as a morbid entity. There are only scrofulous affections, and there is scrofulosis, which is only a morbid translation of the lymphatic temperament. He did not know that the subjects of scrofulosis were more apt than other persons to become tuberculous. Scrofulosis, however, may so modify the vital tissues as to render them more apt to become tuberculous. Such is the opinion expressed by M. Bouchardat in his recent lectures. It is therefore erroneous to include many of the manifestations of tuberculosis under the head of scrofula.

Osteotomy for Rachitic Curvations of the Bones.—A memoir on this subject by Dr. Bœkel, analyzed in *La France*

Médicale (1881, p. 411), gives an account of the method of operation in these cases.

The time of operation depends upon the condition of the patient. It may be carried out when the manual osteoclastic procedure has failed: the latter should in every case be first attempted. The operation should not be performed until the cause which has softened, deformed, and again hardened the bones has been removed. The operation of osteotomy, according to M. Bœkel, should be subcutaneous, sub-periosteal, and total; it may be linear or wedge-shaped. It is performed as follows. 1. Incision of the soft parts as small as is possible, and simply sufficient to permit the play of the scissors; this incision should be vertical, and should go straight down to the bone. 2. The periosteum should be stripped with the aid of the handle of the bistoury or by means of a special instrument. 3. The bone should be divided at the point of maximum curvation. The section should be total: if partial, troublesome suppuration or other difficulty is apt to be caused by the necrosis of splinters of bone broken off in straightening. 4. The operation of straightening then follows. 5. Then finally comes the dressing, which should be performed by the antiseptic method without immediate reunion.

The operation almost always results favorably. There is scarcely any reaction. Consolidation takes place, with rare exceptions, within four weeks, and is durable. Of one hundred and eighty-one cases operated upon by M. Bœkel, osteo-myelitis has never supervened, nor have any terminated fatally.

Aspidospermin—the Active Principle of Quebracho.—At a recent meeting of the Greifswald Medical Society (*Deutsche Med. Wochens.*, 1881, p. 208) Dr. Eulenburg read a paper on the active principles of a number of drugs which have recently come into vogue, and among them of the alkaloid aspidospermin extracted from quebracho bark. Gehe & Co., the well-known chemists, have made a citrate. It occurs as a yellowish-gray powder or in rhombic crystals, and, contrary to the statement made in Gehe's circular, is insoluble in water. It is soluble, however, in fifty parts of water to which four or five parts of nitric acid have been added. In cold (absolute) alcohol, ether, and glycerin the preparation is scarcely at all soluble. Boiling alcohol, however, dissolves one part to ten. The acidified watery solution shows a somewhat reddish color after long standing, but remains clear. Subcutaneous injections of .02–.04 centigramme in the rabbit failed to produce any marked symptoms. In frogs the aspidospermin caused primary respiratory paralysis.

Papayotin.—In the paper mentioned above, Dr. Eulenburg also spoke of the active principle of the *carica papaya*, a Brazilian fruit used in dyspepsia. Papayotin is extracted from the milky sap and also from the leaves. The preparation of papayotin examined by Eulenburg was insoluble not only in alcohol and ether, but also in hot and cold water and glycerin. Even on the addition of acid but a small proportion of the salt was soluble. Experiments made as to the digestive properties of papayotin were negative in their result. Albumen remained undissolved.

Hypodermic Administration of Iron.—Eulenburg, in the paper above alluded to, spoke also of the hypodermic administration of iron, the most convenient preparation of which for this purpose is, in his opinion, the pyrophosphate, with citrate of sodium,—a preparation to be recommended on account of the large proportion (26.6 per cent.) of iron which it contains. In watery solution 1–5 it may be used without local irritation. Within half an hour the urine shows iron.

Epithelioma of the Tongue followed by Secondary Deposits in the Heart.—Dr. Ch. Féré (Société Anatomique, *Le Progrès Médical*, 1881, p. 281) reports the case of a man of 64, whose tongue was removed for epithelioma. The disease recurred, and the patient finally died of exhaustion. At the autopsy the organs in general (except, of course, the tongue and neighboring ganglia) were found healthy. In the wall of the left ventricle, however, were three pea-sized nodules of a typical epithelioma.

Thymol in Ringworm.—Mr. Malcom Morris recommends the following:

℞ Thymol (vel Menthol), ʒss;
Chloroformi, ʒij;
Olei olivæ, ʒvj.—M.

To be painted or gently rubbed on the part.

The cash income of St. Bartholomew's Hospital for 1880 was three hundred and eighty-five thousand dollars.

EDITORIAL.

PASSING ON THE OTHER SIDE OF THE WAY.

THE trial and acquittal of Lizzie Aaronson for infanticide has recently drawn attention very forcibly to a weak link in the chain of Philadelphia's charities. Brought to this city and deserted upon the eve of maternity by her seducer, she applied to several institutions for relief, notably to the City Hospital, to the Home Mission, Christian Association, etc. At the Board of Guardians' office she was required to make affidavit as to the name of her supposed husband, and, failing to do this, was refused admission to the Almshouse.

At no other place was relief found, until she was given shelter by a prostitute of the lower class, whose male paramour finally turned her out, when she dragged herself into a low lodging-house, and by pledging a ring secured a room for the night. The next morning, in the court below, the dead child was found by the police. Skilfully directed expert testimony, aided by sympathy on the part of lawyers and judges, succeeded in picking flaws and securing a verdict of acquittal, which in turn was followed by a shower of newspaper articles, mostly censuring the Guardians of the Poor and hospital authorities for their want of the common feelings of humanity. Very few, if any, editors seem to recognize the fact that a hospital must be managed upon business principles,—that it cannot afford relief beyond the means at its command, and that the cases must be rightly selected for admission. To put a lying-in woman in a general hospital is, of course, to expose her to a great risk of death, and is unjustifiable.

That there is at present excessive difficulty in getting patients into the city hospital we know from experience, and in the instance of Lizzie Aaronson the rules seem to have been applied with brutal indifference,—an indifference which we fear is shared by many persons in our midst whose position in society is far above that of the Almshouse officials.

It will, however, be well worth the sacrifice of one foundling if general attention is called to the whole subject. The abhorrence of unchastity is of course very commendable, but the peculiar development of it witnessed in this City of Brotherly Love is not so savory. After a good deal of experience, we have failed to find one fashionable saloon or even one religious parlor whose doors are shut against any young man of ability and social position because he is unchaste, even though his amours are not hidden; and every one who knows anything about the matter knows that men who have been notoriously loose in this respect continually contract brilliant marriages. Yet when a poor, deserted woman, whose sin perhaps has been almost forced upon her by circumstances, comes to the hour of her travail, she must needs lie in the streets, or, if she be fortunate, be taken into the city hospital, to be herded with those who are hopelessly deep in the mire of impurity, and to have all opportunity of rescue denied her. Most of our readers have heard of the Preston Retreat, an institution which receives married women only for confinement. Married women in our city prefer their own rooms, and so generally have comfortable homes that they are rarely willing to enter a charity. The result is that, so far as our knowledge or belief goes, no money devoted to benevolence accomplishes as little for the amount spent as does the foundation of the Preston Retreat. The managers of the Preston Retreat, however, are

not to be blamed for the restriction of their trust to married women, as the condition is imposed by the will of Mr. Preston. The managers of the Women's Hospital of this city have no such excuse: their charter binds them in no way; they are responsible for their own acts; and with cold inhumanity have they shut their doors against the most pitiable of all human beings.

Until, through the efforts of Dr. James W. White and others, some few years since, the State Hospital for Women was made an active reality, there was no hope in this city for a poor woman who had sinned only once, except to go down to the very depths of depravity, when the Magdalen Asylum would welcome her.

The State Hospital has throughout its course met with opposition from the class who shut the doors of other charities. We have seen a letter, signed by five or six prominent clergymen, protesting against the institution being placed in a certain respectable neighborhood, and asking that it be put in a well-known haunt of prostitutes, where the women would be placed under every temptation to plunge into a career of vice. It was a curious commentary upon this letter that the first applicant for relief was a Sunday-school scholar of one of these very gentlemen, who thought his church's atmosphere would be polluted by the hospital being within a few squares of it.

Some years since, puerperal fever broke out suddenly in the State Hospital for Women: two patients died. There were ten in the house awaiting confinement, two being in the very pangs of labor. It was necessary to do something at once. A carriage was secured, and the women taken to the Women's Hospital by the President of the State Hospital; but they were refused admission, although the offer to pay their board was made. Truly, the ways of the unforgiving are hard.

The State Hospital for Women has been conducted with the most rigid and successful economy; we see by the last report that the average cost per patient, exclusive of rent, was $3.50 per week; yet it cannot receive a third of the applicants. In the eight years since the opening of the institution, 1800 women have presented themselves, whilst only to about 500 has it been possible to afford shelter and relief; 1300 have had to be cast out, thrown into the whirlpool whose abyss is moral and physical death. Of those admitted to the hospital, it is said, nearly 90 per cent. have been permanently saved from a life of shame. Will our readers keep these facts before wealthy philanthropists?

ALCOHOL.—Every one who has made many microscopic examinations of objects and especially of solutions which have been exposed to the air is familiar with one characteristic of the saccharo-mycetes or sugar-fungi,—namely, their ubiquity. The yeast-fungus is always lying in wait to spring into active life when a suitable home is offered it. Under these circumstances it is not surprising that M. A. Müntz, a French chemist, has succeeded in detecting alcohol in rain-, sea-, and river-water, as well as in the general atmosphere and in rich soils. Sewage was found to be very rich in alcohol.

LEADING ARTICLES.

A PREDICTION VERIFIED.

EDITOR OF THE MEDICAL TIMES:

THE disease known as anthrax, *charbon, sang de rate, milzbrand*, etc., has been demonstrated by so many competent observers in different parts of the world (Davaine, Koch, Pasteur, Greenfield, and many others) to be due to the multiplication in the body of the affected animal of a minute vegetable organism, the *Bacillus anthracis*, that additional testimony will scarcely be deemed necessary to establish the truth of the proposition by those who are familiar with the evidence upon which

it rests, while for those who are not familiar with this evidence the simple facts which I have to relate will have but little weight, as it is only by such extended and carefully conducted experimental researches as have been made by the savants referred to that the exactions of science can be met. However, my single experiment has a special interest, as it shows that the truth stated at the outset of this communication rests upon a sufficiently solid foundation to justify a prediction by Burdon Sanderson of what would happen if a minute quantity of dried blood containing *B. anthracis*, which had been in his possession for seven years, should be introduced beneath the skin of a mouse.

I am indebted to Prof. J. Newell Martin, of Johns Hopkins University, for the specimen which has enabled me to make this experiment, and also for the privilege of reading Dr. Burdon Sanderson's letter accompanying it.

The only portion of this letter which it is necessary to quote is the following:

"I send you the material. I started from it the last experiments I made on this subject. It was then five years old, and consequently is now seven or eight. *I have no doubt that you will find that if worked up with salt solution and injected into a mouse, you will have the spleen after from twenty-four to thirty-six hours enlarged and infiltrated with Bacillus.*"

This prediction has been fully verified by the result of my experiment.

The material referred to was enclosed in a glass tube, and did not, I should judge, weigh more than the sixth part of a grain. As soon as I was able to obtain a living mouse, I added a little salt solution to this material, in accordance with the directions contained in Burdon Sanderson's letter, and injected a few minims of this beneath the skin of the little creature. The injection was made at 2 P.M., June 4. The mouse was alive at 10 A.M., June 5 (Sunday), but upon returning to my laboratory at 3.30 P.M. I found it dead, and upon making a post-mortem examination verified the presence of the bacillus in considerable abundance in the spleen. This bacillus resembles exactly the Bacillus of milzbrand as photographed by Koch (Beiträge zur Biologie der Pflanzen, Bd. ii., Heft 3), and corresponds with the descriptions given by those who have studied *Bacillus anthracis*.

I may say, in conclusion, that I have not before met with anything like it in the blood or in the spleen of the numerous animals (rabbits or rats) which have been the subjects of my experiments during the past two years (injections of saliva and of various septic fluids. See my special reports to the National Board of Health).

GEO. M. STERNBERG,
Surgeon U.S.A.

BALTIMORE, MD., June 5.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, FEBRUARY 24, 1881.

Dr. M. LONGSTRETH in the chair.

Report of a case of typhoid fever (?) *in a child æt. ten months.* By Dr. LONGSTRETH.

DR. LONGSTRETH said that he had been called upon to make the autopsy in this case, and regretted that the history furnished in connection with the specimens was necessarily so imperfect. He was induced to speak of the case as one of typhoid fever solely from the post-mortem evidences. The clinical history, furnished by the attending physician, Dr. Scott, was as follows. The child, female, light mulatto, æt. 10 months, nursed at the breast, taking no other nourishment, but was in the habit of drinking ordinary hydrant-water. She had been strong and well until the present symptoms set in. For two or three days previous to January 6, 1881, the mother had noticed that the child did not play or take the usual notice of things, and was weak, but did not regard her as very sick. On examination, the child was found pale, dull, and could be roused only by extra efforts, and immediately fell asleep again. There was no desire for food, tongue coated white, bowels obstinately constipated, requiring repeated doses of castor oil, and finally an enema, to produce their evacuation. The pulse was about normal in rate, but weak. The skin was dry, but did not give a sensation of heat to the hand. There had been no epistaxis, and the lungs were free from any abnormal physical signs. During the second week the physical signs remained as noted, except that now pain in the abdomen and diarrhœa occurred. The fecal discharges were of grass-green color. Appropriate remedies relieved the pain, and the diarrhœa was easily and promptly checked. The child progressively became weaker, and remained in the same somnolent condition. She was roused and proper and abundant nourishment was taken during the whole course of the illness. Death occurred in the early part of the third week from the commencement of the attack.

Post-mortem Examination, made twenty hours after death.—Rigor mortis firm. Posterior parts of the body discolored. Emaciation marked. The great cavities and their serous lining showed no abnormal conditions.

The right side of the heart was relaxed, and contained considerable fluid blood and soft clots extending into the great vessels connected with the auricle and ventricle. The left side was nearly empty, the left ventricle firmly contracted. The heart-muscle was pale, rather friable, but not fatty. The lungs showed considerable posterior congestion and a few small areas of collapse, but otherwise were normal. The bronchial tubes contained considerable frothy mucus, but the mucous membrane gave no evidence of any inflammatory change, though parts of the respiratory tube were of a reddish color.

The spleen was firm, a little swollen, pale externally and internally, of a dark-reddish hue; its pulp was moderately resistant, and did not exhibit the appearance so constantly seen in the typhoid fever spleen.

The kidneys were nearly typically normal in appearance; the only alteration was a very slight swelling, and an opacity of the cortical portion difficult to differentiate from the general paleness of all the organs.

The liver was pale, its edges very slightly rounded; on section, its tissue was anæmic and appeared homogeneous. The bile in the gall-bladder, moderate in amount, was pale green and mucus-like.

The stomach exhibited a slight swelling of its mucous membrane, and contained, floating in a small amount of fluid, some milk-curds.

The intestine, throughout its extent, exhibited marked alterations. Externally, while generally pale and slightly opaque, at parts reddish patches of coarse injection were seen; but the peritoneum was unchanged.

Its mucous membrane throughout, but more markedly in some parts than in others, showed a distinct but not severe catarrhal inflammatory condition. All the Peyer's patches were more distinct than normal, and, as the examination of them progressively approached the ileo-cœcal valve, they were found more elevated and prominent. The few lower patches were very marked in this state, and their surfaces were uneven, but to the naked eye there was no evident ulcerative destruction of the mucous membrane overlying them. The patches were of unusual length, considered proportionally to the relative size of the intestine. The solitary glands of the ileum, as well as of the colon, were enlarged and prominent, and the mucous membrane of the latter also showed catarrhal changes, but to a less degree than in the small intestine. The appendix vermiformis was swollen, thickened, and gave a feeling of firmness to the finger, but contained only fluid contents.

The mesenteric glands were large and swollen, especially the ileo-cœcal gland.

The contents of the gut throughout were pale yellowish and to a great extent fluid, but some firmer masses of a yellow color were present.

The bladder was empty. The generative organs were normal.

Microscopic Examination.—Portions of the intestine were placed in Müller's fluid overnight, to prevent alteration until sections could be made the following morning by freezing. The Peyer's patches at the time the sections were made showed a much greater prominence than when removed from the body. This change was apparently due to a reduction in the swelling of the surrounding mucous membrane, etc., from the escape of fluid.

The lymph-follicles, as now seen with the microscope on the table, are crowded with the small cell-elements, which at the peripheral portions are arranged in straight bands, while in the central parts the corpuscular elements are heaped together in a confused manner. In some of the follicles their centres are evidently undergoing softening, or at least the fibrillar tissue is less resistant and the unhardened tissue has given way. The prominence or projection of the patch is very great, and, as viewed with a lens of low power, is seen to exceed considerably the thickness of the surrounding intestinal wall. In one of the sections the mucous membrane overlying the follicle is seen to be removed, and the infiltrated follicular tissue is exposed, giving the appearance of a commencing ulcerative destruction.

From this brief note of the microscopic appearances presented by this specimen, it is evident that the conditions resemble those found in unquestionable cases of typhoid fever at certain stages of this disease.

Remarks.—As already remarked, in presenting these specimens to the Society, the clinical history is entirely defective in furnishing a proof, or even a hint, that this case was one of typhoid fever, and it is not claimed that the post-mortem evidence is decisive. However, since the knowledge of the symptoms of this disease occurring at this period of life is very meagre, and the autopsy records of the anatomical changes in the organs are so very few, we are possessed of very insufficient guides to lead us to determination of the nature of the alterations here found.

If the case during life had been attended with prolonged diarrhœa, the presence of this symptom might furnish us with the explanation of the enlargement of the lymph-follicles and the mesenteric glands. The rapid emaciation and the condition of the other organs besides the intestines are not inconsistent with the occurrence of a febrile disease, the presence of which, owing to the absence of a thermometric record, may have been overlooked. The reasons for suggesting the ty-

phoid nature of the disease have already been given.

Dr. TYSON thought the specimen, if not one of typhoid fever, was an anomalous one, in that the agminated glands were enlarged, although in a case of such short duration; for in *chronic* intestinal troubles such a condition of Peyer's patches, as well as of the solitary glands, is not unusual. He would ask Dr. Longstreth whether the surrounding hygienic conditions were such as to suggest any source of infection.

Dr. LONGSTRETH replied that the child was at the breast, but of course must have occasionally had water to drink, which might have been the vehicle of infection if such existed.

Dr. ESKRIDGE said that typhoid fever in the young ran a different course from the disease in the adult. According to his experience, it usually ran its course in two weeks, or less. In one patient under his care, where death resulted from hemorrhage from the bowels during convalescence, the fever had run its course in eleven days. Text-books did not sufficiently emphasize the difference of the symptoms and duration of the fever occurring at the two periods of life mentioned; although within the last two years Dr. Jacobi, of New York, in one of the leading medical journals of his city, had called especial attention to the frequency of typhoid fever in children. He stated that it is milder, that it runs its course more rapidly, that the temperature rises at the beginning and falls at the close more abruptly, that the fever takes on more of the type of remittent (for which it is often mistaken), when it occurs in children. The doctor of late had been much interested in collecting cases of typhoid fever in the adult with irregular temperature records, and related cases to illustrate.

Dr. O'HARA asked whether the other children who had died in this family had shown the same symptoms, at what intervals had the fatal cases occurred, and whether anything like a constant cause could be detected.

Dr. FORMAD inquired as to the possibility of syphilis.

Dr. LONGSTRETH, in reply to the last two speakers, said that, as he had merely made the post-mortem examination, and was unacquainted with the family, he was unable to say anything positively, but as far as syphilis went, the history and absence both of skin eruptions and signs of chronic wasting would indicate its probable absence.

Dr. FORMAD said, in explanation of his question, that the microscopic examination suggests a cirrhotic induration rather than ulceration; in fact, portions look as if the follicles were hypertrophied. Birsch-Hirschfeldt has stated that in congenital syphilis there is this increase of the connective-tissue elements in the lymphatic structures. The present specimen would seem to indicate such a condition, while the characteristic medullary infiltration of typhoid fever is absent.

Dr. NANCREDE related a case of a form of fever such as Dr. Eskridge had described, of which he had seen one case, and had heard from his colleague, Dr. M. J. Lewis, had been quite prevalent last summer. To him, such cases seemed merely what the Germans have described as abortive typhoid. As to the present specimen, he would like to ask if any member present knew the *normal anatomical* appearances presented by the small intestine of a child of eighteen months. *He* certainly did not, and before we discussed pathological alterations it would be well to have some knowledge of the normal conditions of the parts. It is certainly true that as age advances it becomes more and more difficult to demonstrate Peyer's patches in a state of health. Dr. Longstreth has said that these patches were not so prominent at the post-mortem as now, as the mucous membrane surrounding them was swollen and infiltrated. Their present prominence is due to the effused products having escaped while the tissues have become condensed by the reagent. May it not only be possible, but probable, that these glands are normally as prominent as in the present specimen in children of this age? *A priori*, as we know that they gradually disappear normally with advancing years, it is but fair to infer that, like the thymus and other glands, their appearance a short time after birth is far different from that to be found at but a comparatively slightly later period of life.

Dr. O'HARA asked whether Peyer's patches could not become enlarged from any other cause than typhoid fever.

Dr. TYSON said that experience thus far had shown no other cause to be efficient, although there is no reason why there might not be some other. In the present case the diarrhœa and acuteness of the attack precluded the idea of syphilis. As to the duration of typhoid fever in children, he thought that all authors agreed that it ran a much shorter course in children than in adults, rarely lasting in the former more than two weeks.

Dr. TYSON replied that he was unaware of any such.

Dr. LONGSTRETH asked Dr. Tyson if he was aware of any case of typhoid fever on record in an infant under one year of age.

Cystic tumor of the breast. Presented by Dr. LONGSTRETH for Dr. PACKARD.

Miss ——, æt. about 45, a well-nourished person, and always in enjoyment of good health, with the exception of some functional nervous disorders, perceived during the summer of 1880 a small lump at the upper and inner border of the left mammary gland.

She suffered no pain except after it was handled, but was alarmed by its steady increase in size. It was removed on January 25, 1881; it had reached the size of an Eng-

lish walnut, and proved to be a cyst. During the operation, notwithstanding careful manipulation, the wall gave way at one point, and a quantity of liquid like thin milk was discharged; unfortunately, none of the fluid could be collected for examination. The mammary gland seemed to be healthy, and was left entire.

A microscopic examination was made, the section being taken from the border of the cyst, including a portion of its wall and the adjacent glandular tissue. The cyst-wall was seen to be made up of condensed fibrous tissue, in which the remains of glandular structure were apparent. The near-lying acini or tubules were found slightly dilated and their epithelial lining stained more deeply, and the cells appeared enlarged or hyperplastic, as though from irritation of the adjacent cyst. The other portions of the gland seen in the section showed nothing abnormal.

Remarks.—It is unfortunate that none of the fluid could be collected for examination, but the exigencies of the operation prevented it, and at a later examination of the cyst no fluid was to be found in it. Attention was given to the intima of the cyst-wall, but nothing was discoverable in its structure that gave any evidence of the nature of the cavity or its contained fluid. It seemed probable, from the appearance of the fluid and the condition of the neighboring acini, that the cyst was to be classed as a retention cyst of the mammary gland from (unknown) obstruction of some of its distant tubules.

Dr. TYSON was inclined to consider that the tumor was a "retention cyst."

Cancer of stomach and liver. By Dr. E. T. BRUEN.

These specimens exhibit an encephaloid cancerous growth, embracing the entire anterior wall of the stomach. The largest masses of the new formation are distributed at the junction of the œsophagus with the stomach, although the œsophagus is not involved. The mucous membrane of the stomach is not ulcerated, but the masses are very large, and as felt through the anterior wall they conveyed the idea of a triple layer of figs,—that is, a well-flattened yet decidedly thick and bulky mass, fully four inches in breadth by seven vertically. The growth has caused considerable dilatation of the stomach, especially the cardiac extremity. Extending from the lesser curvature of the stomach can be found a chain of enlarged lymphatic glands running up under the fissure of the liver, between the right and left lobes. This chain of glands commences around the pancreas, but the structure of this gland is not involved.

Cancerous nodules are to be seen in the liver; the largest nodule, in the left lobe. In the pleura of the right side nodules are found which microscopic examination has shown to be cancerous.

I also exhibit a portion of the skull, with a developed nodule in the periosteum, of the size of a walnut.

These specimens were removed from the body of a man 40 years of age, with a good family record, without history of cancer or scrofula.

The sequence of the cancerous development is as follows. In June last, about five months prior to the date of his death, the tumor of the stomach developed. Six weeks before death, the tumor in the liver was diagnosticated; some three weeks before his death, the nodules in the pleura were discovered.

The clinical history is a recital of the usual symptoms of similar conditions. It is interesting to note that vomiting was never a symptom unless very inappropriate food was used; there was never vomiting of blood, but large amounts of gas were frequently passed per mouth and anus. There was no constipation. To explain this absence of frequently-expected symptoms, I would note that the pylorus was not involved; thus vomiting was not induced, because the contents of the stomach could readily pass into the intestine; and, as the liver was only involved in the later history of the case, intestinal digestion was not impaired.

Pain, however, was a prominent symptom, and the suffering was much increased by the developments in the pleura.

Another interesting symptom was a total paraplegia. The power of motion in the legs was abolished, and there was no control over the bladder or rectum. This paralysis appeared some four weeks before death. It fully developed itself in about one week, leading me to suspect that a similar change would be found in the membranes of the cord to that noticed in the pleura. At the autopsy the cord was examined in its entirety, and nothing abnormal could be detected. In fact, the cord has been cut into sections and is used to demonstrate the normal histology of that tissue to the class at the University of Pennsylvania.

A loud systolic bruit could be heard over the region of the aorta, audible just below the ensiform cartilage anteriorly, diminishing as the aorta passed downward. It was heard posteriorly over the dorsal spine quite distinctly. This bruit was not affected when the hand-and-knee position was assumed, or when an effort was made to draw the tumor downward into one or other iliac region, which could be partially accomplished. The persistence of murmur was probably owing to the constant pressure of this large mass on the aorta; and, owing to the fact that most of the growth affects the cardiac end of the stomach, it could not be dragged away from the vessel as one could drag a tumor in some other part of the stomach.

Yet, for all this, I felt I could exclude aneurism even in the early stages of the growth,

since aneurismal pressure-signs were absent, and there were no evidences of systemic conditions which predispose to disease of the arterial coats, such as syphilis, alcoholism, rheumatism, and the like; and these evidences I regard as of ultimate importance.

Finally, I would say that the movable character of the tumor above referred to, and the absence of symptoms of intestinal indigestion, were important evidences that the location of the primary tumor was in the stomach. I think you will agree that cancers of the anterior wall, since they grow backward and inward, are not necessarily more prominent to palpation during life than are tumors of the posterior wall of the stomach. This tumor seemed to be situated just beneath the skin, so superficial did it seem during life. But I have examined cases in which the tumors seemed equally superficial during life, yet autopsy revealed the location of the disease in the posterior wall.

Sections of the cerebral ganglia, with remarks on their anatomy and lesions. Presented by Dr. CHARLES K. MILLS.

The specimens exhibited, nine in number, were—(1) transverse and vertical sections; (2) longitudinal and vertical sections; and (3) horizontal sections of the ganglia. The preparations were not for microscopical study, but were for the purpose of illustrating some points in connection with the coarse examination of the brain, with the view of accurately localizing and recording lesions. The following is an abstract of the remarks made by Dr. Mills:

Although physicians seem lately to have awakened to the importance of carefully describing the limits of cortical lesions, they do not appear to be as fully alive to the equally important matter of definitely localizing lesions of the deep parts of the brain. By studying transverse, longitudinal, and horizontal sections of the cerebral hemispheres, one can soon obtain a clear idea of the size, shape, and normal appearances of the ganglia, and of the intervening and surrounding white matter. On the whole, perhaps, vertico-transverse sections will be the most available and lead to the least confusion in making post-mortem examinations. The profession has become familiar with the appearances presented by such sections from the plates in the works of Charcot, Ferrier, and others. The appearances of longitudinal and horizontal sections are not so well known. In the Annals of the Anatomical and Surgical Society of Brooklyn for January, 1880, and in *Brain* for July, 1880, Prof. J. C. Dalton, of New York, has published papers on the *corpus striatum*, from a study of which many useful points can be learned with reference to longitudinal and horizontal sections. I show you sections similar to those figured in these articles, and will quote his remarks on horizontal sections: "In horizontal sections of the brain, the size and form of the cerebral ganglia vary greatly according to the level at which the section is made. At the level of the corpus callosum only a little of the arched portion of the corpus striatum is exposed, and none of the lenticular nucleus is visible. Somewhat below this, at the level of the fornix, the arched portion of the corpus striatum disappears, but there is a large oval section of the head in front, and a small one of the surcingle behind. Lower still the lenticular nucleus comes into view, separated from the head of the corpus striatum by the distinctly marked anterior prolongation of the internal capsule. At the level of the anterior commissure the lenticular nucleus and the head of the corpus striatum begin to fuse with each other, owing to the partial disappearance of the internal capsule between them. At this level the head of the corpus striatum is much reduced in size and altered in shape. The lenticular nucleus occupies a position outside and behind it; and still farther back is the section of the surcingle, which is here beginning to run downward and forward, along the roof of the inferior horn of the ventricle. At a lower section still, the head of the corpus striatum would be united with the cortical convolutions in front of the Sylvian fissure, and the surcingle with the gray substance of the amygdala."

Attention might be called to a few points of special interest.

An erroneous idea of the exact position and relations of the ganglia may result from always studying brains after they have been removed from the skull. The superior surfaces of the intra-ventricular striate body and of the optic thalamus do not present a horizontal plane when the brain is in position in the skull, as they appear to do after it has been removed. Cutting into the lateral ventricles, with the brain still resting on the floor of the skull, it will be found that the faces of these ganglia are nearly perpendicular.

The slight depth of a large portion of the caudate nucleus might, perhaps, mislead in careless autopsies. At the head of this nucleus, where it partly blends with the lenticular body, the depth of gray matter is considerable, but it is slight as you go backward, ranging, in some measurements which I have made, from one-eighth to one-third of an inch.

When examining the lenticular nucleus, the difference in color of its different segments should be borne in mind. These are very marked, and, through ignorance of them, I have seen the error made of supposing that a normal lenticular ganglion was invaded by a large sclerotic nodule. On transverse sections in the anterior third a uniform grayish tint is presented, but in the posterior two thirds, two, and sometimes three, colors or shades can be made out,—one the grayish hue alluded to, and the others yellowish or yellowish-brown. On making a central longitudinal incision,

the uniform gray tint of the heads both of the caudate and lenticular bodies is continued backward the whole length of the section, gradually tapering, however, and passing beneath the yellowish segments. These appearances are given by the two outer segments seen in the transverse cut. In infancy the differences in color between the parts of the lenticular nucleus are not so well marked as they are later in life.

We cannot be too particular in localizing lesions, and especially isolated lesions, of the ganglia and tracts. By so doing we may help to solve the problem—now so obscure—of the functions of these parts. The landmarks, as I have tried to show, being plain, this localization is not in reality a difficult matter. In some respects, indeed, it is less troublesome to locate and record lesions in the ganglia and capsules than in the convolutions, because in the latter we may have confusing secondary and tertiary deviations from the usual forms. In considering isolated lesions it must not be forgotten that they may exert pressure on surrounding regions.

According to Nothnagel (Ziemssen's Cyclopædia, vol. xii. p. 145), "lesions in the main cerebral ganglia from which spring the motor tracts of the crura cerebri, the *nucleus lenticularis* and the *corpus striatum* (*nucleus caudatus*), inasmuch as they are the most common of all, give rise to the most familiar group of symptoms." It seems to me, rather, that these lesions have taught us less that is exact than those of almost any other well-studied region of the brain, because, in the first place, absolutely isolated lesions of the ganglia and capsules are by no means common, and, secondly, because of the careless manner of making and recording lesions of these regions. It is probable that in the ganglia we have, in some way, representatives of each of the differentiated centres of the cortex. Certainly, as suggested by Charcot, the three gray nuclei of the lenticular body may be so many centres endowed with distinct properties and functions.

PHILADELPHIA ACADEMY OF SURGERY.

STATED MEETING OF MAY 2, 1881.

DR. R. J. LEVIS, Vice-President, in the Chair.

LARGE VESICAL CALCULUS.

DR. THOMAS G. MORTON exhibited a calculus weighing four and one-half ounces, and measuring six and one-half inches in circumference, which he had removed by a transverse vaginal incision from the bladder of a lady seventy-nine years of age. She had presented symptoms of vesical disease for forty years, but had never allowed an examination to be made. The stone was so large that it could not be turned within the bladder, and considerable difficulty was experienced by the operator in extracting it, as the instruments at hand were better adapted to the extraction of a small stone through the urethra. After the stone was removed, silver sutures were introduced, and the patient made a rapid recovery.

TWO CASES OF EXCISION OF PORTIONS OF THE INFERIOR DENTAL NERVE, FOR NEURALGIA.

Dr. Thomas G. Morton read the histories of the following cases:

Case I.—E. H., aged seventy-one, gave the following history. About nine years ago, began to have pain on the left side of the lower jaw. The first attack came on at dinner; it lasted for an instant only, and no further pain was felt for several days; it then recurred, and since, at short intervals, the attack has been very severe; generally came on during eating, but after moving the muscles of the jaw the pain subsided; a frequent cause of pain was from the use of the tooth-brush, talking, swallowing,—in fact, any movement of the jaw; although the attacks of pain would appear at night, disturbing sleep, not infrequently several times during the night. During the earlier part of the past nine years of suffering there were times—perhaps two or three—when there was an absence of pain for several weeks, but of late years the distress has been nearly continuous. Had tried all remedies suggested, without any relief. The pain seemed to originate at the angle of the jaw, and generally progressed forward into the teeth; now and then it would shoot into the temporal and facial region. Several molar teeth were removed on account of the neuralgia, but not the slightest improvement was observed. During the past few years, and especially the last twelve or fifteen months, the agony was great, causing loss of appetite, flesh, and sleep; and, indeed, the suffering made inroad upon the general nervous system.

In consultation with Dr. Agnew, it was agreed to excise a portion of the inferior dental nerve, and to make the section just above the jaw-angle. There was no abnormality of the jaw as far as could be observed, save a contraction incident to age and from the extraction of teeth. The diagnosis made was pressure from this upon the nerve-canal.

March 21.—The bone was exposed and the trephine was applied. As soon as the instrument had penetrated the cancellated structure, the circular portion of bone was removed, and the nerve and artery were seen lying directly in their usual course; the former was lifted on a hook, and after being thoroughly stretched half an inch was excised. There was no bleeding, for the artery was not injured. The wound was brought together with silver sutures; these were removed on the fifth day. In a fortnight E. H. was out driving and quite well. A few days after the operation he experienced a few (perhaps three

or four) twinges of pain, but momentary. A month has elapsed since this, and the relief has been entire; he has had no return, even of a twinge, as he writes me:

"I can eat, masticate, and swallow with a comfort and confidence that I have not known for years. My health, especially my nervous force, has much improved since the removal of the nerve."

The second case was that of a gentleman aged fifty-six, of this city. His symptoms correspond so nearly to those of the former case that the account need not be repeated. The length of time, however, had been much shorter, the duration of pain extending only through three or four years. He had tried every conceivable form of treatment without any effect other than the injury of general health from anodynes. The pain in this case was on the right side, and in removing the section of bone some points of special interest occurred, which are perhaps worthy of record.

April 13.—The trephine was applied at the usual place, midway between the upper and lower edge of the jaw, above the angle; and after gaining what seemed to be the centre of the structure the nerve could not be found, nor any evidence of the canal, nor was there any special hemorrhage, so that I reapplied the trephine, and a few turns carried the instrument through the entire thickness of the jaw. A careful survey showed the nerve much out of its usual course; it was found with a probe at the very uppermost part of the sawed section, in conjunction with the artery; a probe was passed around it, and it was drawn down and cut off. The artery, which was pricked, was tied in two places by ligature, and the wound was bought together by silver sutures. An excellent recovery followed, with an entire relief from the neuralgia, the patient being in a fortnight attending to out-door business, although the wound had not yet closed.

In both cases there was complete anæsthesia extending along the jaw and involving the soft tissues to the middle of the lower lip.

Dr. J. Ewing Mears stated that he had had some experience in the treatment of neuralgia of the trifacial nerve, and he thought it important to determine, if possible, before submitting the patient to operation, whether the lesion was central or peripheral. He had observed a number of cases in which excision of the nerve had been performed and the relief had been of a transient character. In operations which he had performed of removal of the alveolar border of the jaw, for the relief of alveolar neuralgia, permanent benefit had not been obtained. In one case he had cut into the inferior dental canal, and had removed a portion of the nerve with the roots of a tooth which were found imbedded in the jaw. The operation did not permanently relieve the pain. Other cases he had treated by long-continued medication, and the results were much more satisfactory than had been obtained by operations.

Dr. Morton said that in one of his cases the irritation certainly seemed to be peripheral, because it was produced by pressure upon a certain spot.

The patient is, at any rate, greatly benefited at the present time, though the neuralgia may recur. He had removed a portion of the second branch of the fifth nerve very often, and, having watched the cases, found them free from pain long after the operation. He thought that union of the divided nerve would not be likely to occur after operating on the inferior dental nerve, because the canal would be obliterated.

Dr. J. M. Barton had treated one of the cases mentioned by Dr. Morton by full doses of the usual remedies, and on account of failure to give relief had advised operation, which the patient at that time refused.

In operating himself, he used a much smaller trephine than Dr. Morton,—an instrument a half inch in diameter being found quite sufficient,—and had found the nerve to be nearer the upper edge of the jaw than the median line, especially in individuals who had lost their teeth, and in whom the alveolar process was absorbed, and who so often are the victims of this painful malady.

Pain returned in some cases for a short time after the operation, but then disappeared, which suggested that the disease was peripheral and the temporary neuralgic pain following was due to the irritation of the diseased portion by the operation, confirming the diagnosis of the disease being peripheral, and making the prognosis of a cure more favorable. When the neuralgia depends on central causes, Nussbaum's operation of ligation of the carotid artery may be proper. Fourteen cases of operation for this cause have been reported, twelve in Europe and two in America. Of these thirteen recovered and one died. Of the thirteen recoveries six were cured, four temporarily improved, one not benefited.

The operation was performed last summer at the German Hospital in this city, by my colleague Dr. F. H. Gross, on a patient in whom all three branches on one side were violently affected. Since the operation the patient has had no pain in the first and second branches, and only an occasional twinge in the inferior dental.

Dr. Mears would not oppose operation in all cases, but his experience convinced him that the results were not as good as usually believed. In view of this fact he thought, in order to obtain more decided effects, operations should include more than excision of the nerve. The branches of the three divisions of the fifth nerve which are involved in the neuralgic condition escape to the surface through osseous rings or canals, each accompanied by an artery and a vein. Assuming

localized pressure as the cause of the affection, this can occur, external to the nerve proper, by encroachments upon the calibre of the canals, as the result of inflammatory or structural changes in the bone-tissue, or by an hyperæmic condition of either artery or vein. Within the nerve abnormal fulness of the minute capillary vessels which permeate its structure could exert sufficient pressure here, as elsewhere in the body. Of these conditions bony constriction must be regarded as an exceedingly rare occurrence, whilst congestions of the accompanying artery or vein, or of the nerve-vessels themselves, may be frequently present. He would suggest, therefore, in all cases where excision of the nerve is performed, that the accompanying artery should be ligated, with a view to remove a probable exciting cause. He was aware of the good results which had followed ligation of the common carotid artery in trifacial neuralgias. This procedure cannot be employed in all cases, owing to its gravity, whilst the ligation of the artery in the canal increases in no respects the risks of the original operation.

Dr. R. J. Levis said that Dr. Morton's paper recalled a similar case in his own practice where the trephine had perforated a shrunken jaw-bone without any untoward symptom following. He had operated in four cases, and in only one was the success permanent. This patient had shown marked peripheral sensitiveness. (Since the meeting a letter from this patient's physician has been received by Dr. Levis, stating that the operation, which was done many years ago, was followed by relief for only a short time, and that the woman is at present a great sufferer from the original neuralgia.) He always used a very small trephine, and would expect the nerve to seem comparatively highly placed in a shrunken edentulous jaw. Failure had always occurred in his experience after Gross's operation of cutting away the alveolar process in case of neuralgia in the toothless jaws of old subjects. Recently, in neuralgia of the alveolar processes, he had dissected up the periosteum by incisions through the gum, detaching it freely from the surface of the superior maxillary bone in the endeavor to relieve the pain; but the result was not satisfactory.

Dr. De F. Willard recollected a case where the pain returned subsequent to operation, but about a year afterwards disappeared, and has not recurred, though many years have elapsed.

OBSCURE CASE OF ENLARGEMENT OF THE HEAD OF THE HUMERUS.

Dr. J. M. Barton presented a child of six years, from whose parents he could get no distinct history, with general enlargement of the upper extremity of the right humerus. Pain was said to have been present for two months, and there was muscular anchylosis of the shoulder-joint. Some of the symptoms suggested central sarcoma of the head of the humerus; but Dr. Barton desired the opinion of the Fellows as to the diagnosis, and asked whether any operative step, such as trephining, scraping out the cavity, if such were found, or excision, would be warranted in such an obscure affection.

Dr. T. G. Morton would be inclined to wait, and then possibly make an incision into the bone with the view of finding a scrofulous abscess.

Dr. O. H. Allis said the same case had applied to him about three weeks previously, with great pain and fulness in front of the shoulder, which was so acute that the child would scarcely allow the shoulder to be touched. He had applied a blister with the result of relieving pain, and had ordered a second one to be used upon the other side of the joint. The condition of the case was quite different now from what it was when last seen by him in his dispensary service.

Dr. John H. Packard thought the subsequent history of the patient would prove highly interesting. The existence of no joint-involvement and no appearance of periosteal abscess, coupled with the facts that tumors of bone are rare at such an early age, and that abscess of bone would hardly exist with as little pain as was at present manifested, rendered the case very obscure. The child, to his mind, presented some of the appearances usually associated with scrofulous affections.

PULSATING TUMOR AT ELBOW CURED BY LIGATION OF BRACHIAL ARTERY.

Dr. R. J. Levis exhibited the patient, who was shown at the November meeting of last year (1880) with an obscure pulsating tumor below the right elbow. He had subsequently ligated the brachial artery at the Pennsylvania Hospital, and the rapid cure of the case proved the tumor to have been aneurismal. There was now to be felt near the median line of the forearm a nodule which was evidently the shrunken sac.

Dr. Mears called attention to the fact that now the sac seemed to be at the radial side of the forearm, though in November the tumor was believed, if an aneurism, to be connected with the ulnar artery. It may have been at the lower part of the brachial. Both radial and ulnar now pulsated at the wrist, and the radial seemed stronger than the ulnar.

SPECIMEN OF ANCHYLOSIS OF ELBOW.

Dr. John B. Roberts presented a specimen obtained from his dissecting-room at the Philadelphia School of Anatomy, illustrating bony anchylosis of the elbow, due apparently to partial luxation backward of the ulna, associated with fracture of the olecranon process.

The altered position of the carpal ends of the radius and ulna, due to the displacement of the upper end of the ulna, was especially pointed out.

JOHN B. ROBERTS,
Recorder.

REVIEWS AND BOOK NOTICES.

ON THE ANTAGONISM BETWEEN MEDICINES AND BETWEEN REMEDIES AND DISEASE. Cartwright Lectures for 1880. By ROBERTS BARTHOLOW, M.D. New York, D. Appleton & Co., 1881.

Probably most of our readers will consider that we have awarded this treatise high praise when we say that it seems to us the most carefully written, best thought-out, and least dogmatic work which we have yet read from the pen of its author. It is indeed a very praiseworthy book; not an original research, indeed, but, as a *résumé* of the world's work upon the subject, the best that has hitherto been published in any language. It is composed of six lectures,—the first chiefly occupied with a history of the subject and a preliminary discussion of terms, etc.; the last, with a consideration of the relations of remedies to disease; whilst the intermediate four chapters are devoted to individual antagonisms. In a notice like the present we cannot, of course, follow discussions in detail; but we desire to call especial attention to the term "antagonism of remedies," because the common use of it seems to us to lead to inaccurate thinking as well as writing. The term "physiological antidotism of remedies" has been suggested and by some used as a substitute for antagonism, but is declined by Prof. Bartholow. It seems to us very clear that both terms should be employed as having different meanings. It is absurd, for instance, to say that one remedy is antagonistic to a second, but that the second is not antagonistic to the first; whilst it is perfectly conceivable—indeed, does happen—that one medicine is antidotal to a second, which is not in turn antidotal to the first. Suppose poison A kills by sweating into fatal exhaustion, poison B arrests sweat-secretion, but kills in overdose by paralyzing the centres of respiration: it is apparent that B would be antidotal to A, whilst in poisoning by B A would be of no service.

On page 69 of Prof. Bartholow's book we read: " . . . but chloral is an antagonist to strychnia poisoning, rather than strychnia is an antagonist to chloral poisoning." By substituting "antidotal in" for "antagonist to," the sentence becomes logical. This distinction is not merely of verbal importance: clear speaking and clear thinking are bound together. Indeed, very many of the researches upon so-called antagonisms throw little light upon the science of the question, however valuable they may be as studies of practical antidotism. When investigators generally recognize the difference in the two terms, we shall have made one step forward.

LECTURES ON SYPHILIS, DELIVERED AT THE HARVEIAN SOCIETY, December, 1876, by JAMES R. LANE, F.R.C.S., Surgeon to St. Mary's Hospital, and Lecturer on Surgery, Consulting Surgeon to the London Lock-Hospital. Second Edition. London, J. & A. Churchill, 1881. Fcp. octavo, 95 pp.

This little book is one of the most entertaining and instructive upon its subject which we have ever read. Mr. Lane has had in view to trace as concisely as possible the progress made of late years in the investigation of syphilitic venereal disease, to point out the generally accepted views of the present time and the principal points of divergence. This he does in a clear and satisfactory manner, describing the discovery of the non-identity of gonorrhœa and syphilis, the differentiation of the chancroid, the "unity" and "duality" theories, syphilization, phagedæna, reinfection, contagion of secondary syphilis, contagion by syphilitic blood, vaccino-syphilis, contagion of secretions of syphilitic patients, hereditary syphilis, visceral syphilis, the modern treatment of the disease, and its legislative prevention. Every physician who desires to be fully informed regarding the progress of medicine, or who wishes to refresh his memory as to the essential points in connection with syphilis, should obtain this little book and master its contents. Its market-price is not high, but it is worth its weight in gold. A. V. H.

DISEASES OF THE JOINTS. By RICHARD BARWELL, F.R.C.S. New York, Wm. Wood & Co.

To one who wishes to add to his library a useful work on diseases of the joints, this book can be recommended. It bears upon every page indications of careful, deliberate preparation. All that could make one master of his subject has been brought under tribute, and the reader becomes more and more impressed with the real value of the work the farther he proceeds in it. It is a book, however, that must be studied,—and studied carefully: it cannot be simply read. Neither can it be snatched up for examination upon a particular point with the view of getting the author's views. The author treats the subject as a whole, and he who would understand him on any one subdivision must pass in careful review all the preceding chapters. It is, therefore, not only unfair, but in this instance especially unjust, to criticise the views expressed at particular points,—since to be full at all points would require endless and tiresome repetition.

The work is abreast of the most modern pathology and therapeutics, and if lacking anywhere it is in surgical details. As these, however, may be found in any general work on surgery, the author has not felt it necessary to be more explicit.

We regret that so valuable a work should reveal its chief defects in the style of its author. After qualifying himself so nobly for his task, it is inexcusable that one so abundantly competent to write good—and by this we mean simple—English should mar a life-work by original word-building and by sentences rendered the more obscure by violation of the first principles of composition.

This, however, is the worst that can be said of the book. The kernel is in the nut, and will richly repay the labor to come at it. A.

A Manual of the Practice of Medicine. By H. C. Moir, M.D.

This work is a compilation, and is a good work of its class, but, in our opinion, it will be a bright day for the medical world when the class for which it is written is extinct. If monographs and treatises on medicine come to be entitled studies or treatises on morbid physiology, original thought will be stimulated, principles will be established of value to direct in special exigencies, and routine methods of work branded as distinctly inferior. The idea prevalent among the laity is fostered by such works as this, viz., that the medical man is near akin to the barbers and alchemists of olden times, that he has a definite recipe for every demand, and the idea is covered up that he is practising on the basis of scientific investigation combined with shrewd observation. But if the lame and the halt must abide, the crutch provided by this book is trustworthy and reliable. The book is a catalogue or dictionary of medicine, etiology, symptomatology, and treatment being each considered in a representative style; and it is worthy of especial mention that the therapeutics advised are in accord with most standard authority. But we cannot but think a book incomplete even as a dictionary when we can read, as on page 376, that digitalis is advised in chronic Bright's disease as a diuretic, and yet its properties as a stimulant to the heart and circulation are not dwelt on sufficiently to guide the venturesome practitioner in his watch for the dreaded symptoms of its toxic action; and this instance is cited as typical, in our opinion, of a defect in method of teaching.

Clinical Lectures on the Physiological Pathology and Treatment of Syphilis. By Fessenden N. Otis, M.D., Clinical Professor of Genito-Urinary Diseases in the College of Physicians and Surgeons, New York, etc. New York, G. P. Putnam's Sons, 1881. Octavo, pp. xvi, 116.

These lectures originally appeared in the columns of the *Boston Medical and Surgical Journal*. They are the expansion and amplification of the views of the author published ten years ago, with such modifications as experience has suggested. We can best characterize their scope by quoting a passage from a review (in the *Lancet*) of Dr. Otis's earlier papers, which he himself adopts: "His views are not based upon the results of any experiments, or new facts, or on the unravelling of observations. They consist mainly of deductions drawn from a close and elaborate reasoning on the acknowledged features of syphilis, in connection with the latest doctrines and hypotheses of certain pathological teachers." Want of space forbids our entering into the details of Dr. Otis's speculations, which must have an interest, however, for every student of—what we may term, in contradistinction to the more routine pickling of diseased organs and cutting and mounting of microscopic specimens—"transcendental pathology." We could wish, however, for a more lucid style, and for the omission of clinical detail, which, though very interesting in itself, distracts the attention from the main course of the argument. A. V. H.

De la Phthisie Pulmonaire et de sa Curabilité. Par Jean-Louis-Simon Joly, Docteur en Médecine. Paris, J. B. Baillière et Fils.

"As our medical practice dates twelve years, and the cases of cure we have obtained are quite numerous, we will only quote the most important observations." These words, on page 70 of this pamphlet, inspire us with enthusiasm, and our fancy depicts emoluments paling the fortunes of the venders of Schenck's Pulmonic Syrup or Jayne's Expectorant; but as we read of the curative influences of powders evolved from "la calcination de petits os de volailles," and of cod-liver oil, we recall that in the shadowy past, in our own land, these measures have been cautiously tried by some bold spirits. For cough our instructor would advise opium, codeia, pills of iodoform; for fever, aconite; for diarrhœa, liquid diet; as tonics, arsenic and strychnia. The *coup de main* is diet. This must be vegetable food strictly, since it is more acceptable to the stomach than animal food, and also vastly superior, because it contains the salts most desirable to secure and encapsulate the tubercle. As examples, French beans and wheat are cited, eggs and milk are approved, and an analysis of these unique foods is appended. Our author's belief is firm that phthisis is tubercular and develops from diathetic predisposition, scrofula playing a foremost part; excessive lactation in women, the fevers, diabetes, and exhausting conditions have a share as predisposing conditions. He disbelieves in the inflammatory origin of phthisis, although he admits a pleurisy is the antecedent of many cases of tubercular phthisis. In climate, the extreme cold of Lapland or an African sun seem to be his Utopia for the phthisical, large, airy, sunny rooms for those who cannot leave home. The thought will intrude itself, "Is there nothing new under the sun?"

DRUGS THAT ENSLAVE. THE OPIUM, MORPHINE, CHLORAL, AND HASCHISCH HABITS. By H. H. KANE, M.D. Philadelphia, Presley Blakiston, 1881.

This is a small octavo book of about two hundred pages, in which are discussed with much detail the various questions connected with the habitual use of the narcotics named in the title-page. The most novel and by far the most interesting portion of the work is that in which chloral is dealt with, the conclusion being reached that it is the most dangerous agent of the class. We notice a rather remarkable statement in regard to the influence of opium. It is stated, "A *lady* who had used morphine by the mouth for sixteen years found her *virile power* during and at the end of that time in no way impaired; if anything, it was increased." We suppose the virile power of a lady must be her husband, either in general or in a particular part. Now, that the husband, either as a whole or in a member, should be increased by the use of opium by the wife, strikes us as worthy of attention.

Usually the English of Dr. Kane is good, and the book not only covers very well its allotted territory, but is more of a contribution to medical literature than are many more pretentious rivals.

APHORISMS IN FRACTURE. By R. O. COWLING, A.M., M.D., Professor of Principles and Practice of Medicine.

In the form of aphorism—*i.e.*, in pithy, clear, but comprehensive sentences—the author has said scores of useful things. Had he been content to employ his skill on the general truisms of the subject, his little pamphlet would have been incapable of harm. As it is, he has essayed the *treatment of the whole domain of fractures in ten pages*, and in this not only renders his work valueless, but even worse,—harmful.

We have nothing to say when men offer to teach music, painting, or a modern language in ten lessons; but when primers step forward and speak authoritatively upon a subject that on the one hand may cripple a patient for life, and on the other filch two thousand four hundred and fifty dollars from the treasury of the doctor (as lately occurred in Erie, Pennsylvania), we cannot regard the matter as a harmless joke, but must urge a protest against all such pretensions to medical teaching. A.

THE DIAGNOSIS OF DISEASES OF THE SPINAL CORD. By W. R. GOWERS, M.D. Second Edition. Philadelphia, Presley Blakiston, 1881.

Most of our readers are no doubt familiar enough with the first edition of this book to know that in its eighty-four pages is contained an excellent epitome of our knowledge concerning spinal cord diseases. Carefully and clearly written, it constitutes, in its original form, a valuable brochure for the practitioner's library; in its present revised shape it is certainly no less satisfactory, and in some parts, especially in the discussion of clonic and tendon reflex, decidedly more satisfactory, than it was as first penned.

A GUIDE TO THE CLINICAL EXAMINATION OF PATIENTS AND THE DIAGNOSIS OF DISEASE. By RICHARD HAGAN, Privat-Docent to the University of Leipsic. Translated by G. E. GRAMM, M.D. New York and Philadelphia, Boericke & Tafel.

This work represents the need of the younger portion of the profession and the students of medicine, but it gives them but a stone. It is too much condensed: in the effort to embrace all the field, it is practically but a slightly enlarged medical dictionary. Fifteen lines are devoted to aneurism, and no mention of symptoms save murmur and dulness over the course of the aorta. In diseases of the brain and its membranes it is much too laconic. The section on the examination of the urine is, relatively, the most comprehensive in the book, thirty pages being devoted to it; while but thirty lines are given to typhoid fever. The physical diagnosis is open to the same criticism: it is good so far as it goes, but the work does not compare favorably with books of its class, such as "Elements of Practical Medicine," by Alfred Carter, M.D., lately published by Presley Blakiston, of this city. E. T. B.

THE HEART AND ITS FUNCTION. (A "Health Primer.") New York, D. Appleton & Co., 1881.

> "A faint cold fear thrills through my veins
> That almost freezes up the heat of life.
> * * * * * * *
> This horrid image doth unfix my hair
> And make my seated heart knock at my ribs
> Against the law of nature."

Fancy calls to mind similar, though less poetic, laments from students after concluding their first course in physiology, and fancy pictures a similar state of mind in the dabbler in medicine who is buried in primers. A study of physiology affords a basis upon which a physician can advantageously advise his patient, but a primer renders a patient self-opinionated. E. T. B.

WHAT TO DO FIRST. By CHARLES W. DULLES, M.D. Philadelphia, Presley Blakiston.

A household proverb, "Necessity is the mother of invention," is set at naught by this work. She is a matron of essentially American stock, and the brains of her offspring are being whittled into imbecility by popular adaptations of medical science, of which this work is a type; or else they become paralyzed into inaction because individuals become unable to dissect "what to do first" from the accumulation of technical knowledge at their disposal.

GLEANINGS FROM EXCHANGES.

Impacted Foreign Bodies in the External Auditory Meatus.—Dr. Francis H. Brown (*American Journal of Otology*, vol. iii., 1881, p. 29) says that, judging from the remarks of some authors, the meatus auditorius is looked upon as a *terra incognita*, much as the colon or the pleural cavity would be, and its investigation to be entered on as we should that of any of the inner organs of the body. Every practitioner should, on the contrary, recognize the fact that the entire passage of the outer ear is within his sight, and that the treatment of its diseases should be governed by the same rules which would dictate his care of any other portion of the body's surface.

After speaking of the various instruments in common use for the removal of foreign bodies from the external auditory meatus, Dr. Brown says the point he wishes to make is that tightly-impacted bodies in the ear *must* be removed; that the practice of allowing them to rest even in cases where no apparent and immediate irritation and inflammatory action are present does not offer assurance that subsequent trouble will not arise, and, in fact, at some time or other, with the accumulation of cerumen in the ear, with the access of cold, or by some other means, the meatus is very likely to take on inflammatory action, in which case the integrity of the middle ear may be jeopardized. If the body is firmly impacted in the ear from the first, its very presence and pressure induce œdema of the meatus, and the longer it remains, the more unsatisfactory will be the attempt to remove it. A sort of burr is often formed, both before and behind the body, caused by the œdema to which the stoppage of circulation gives rise, and this may obscure the body from view. As an example of what may be expected when such foreign bodies are allowed to remain, Mr. Hutchinson speaks of a child with a locust-bean in its ear which could not be removed. The bean soon swelled, and filled the cavity. A week later the child was feverish, had pains in the head, then paralysis of the portio dura came on. Dr. Brown considers the Tiemann bullet forceps the best instrument for extracting, and he gives a note of a case in which an impacted kernel of corn was removed by this instrument, the patient being placed under ether rather than allow the seed to remain and swell within the meatus.

The Influence of Temperature on Absorption.—Sassesky (*Lancet*, vol. i., 1881, p. 637; from *St. Petersburg. Med. Wochens.*) has published the results of some observations on the influence of temperature on the absorption of drugs. These were introduced by the mouth, the rectum, or by hypodermic injection, in the case of persons in good health, and of others suffering from various diseases. Iodide of potassium, salicylic acid, ferrocyanide of potassium, and hydrochlorate of quinine were given in solution by the mouth and rectum, care being taken that each viscus was previously empty. The period after administration at which the drug could be detected in the urine was taken as the indication of the rapidity of absorption. For hypodermic injection, solutions of iodide of potassium and ferrocyanide of potassium were employed. It was uniformly found that, when given by the mouth or rectum, the higher the temperature of the solution the more rapidly it was eliminated, the results varying from two to forty minutes, and depending somewhat on the individual conditions of the patients. The results in hypodermic injection were doubtful. Manassein has suggested that warm liquids cause a more intense hyperæmia of the mucous membrane, and hence are absorbed more quickly. On the other hand, cold liquids cause an initial contraction of the vessels, which has the effect of delaying absorption.

Dangers of Chlorate of Potassium Exaggerated.—Dr. Harkin, in a letter to the *Medical Times and Gazette* (vol. i., 1881, p. 413) challenges the correctness of Dr. Jacobi's statements regarding the dangers of using chlorate of potassium. He says he has prescribed the chlorate through the medium of the maternal circulation, to the languishing fœtus in utero, with the greatest advantage; to the baby and the nursing mother (to the former directly as well as through the instrumentality of the mammary secretion); to the child in marasmus and struma; to the anæmic and menorrhagic female, and to sufferers from every phase of the hemorrhagic diathesis; in skin ailments from acne punctata to the boil and carbuncle,—in fact, to patients suffering from every class of disease depending upon debility or subaëration, from the time of childhood to the climacteric period of existence,—and he has never witnessed a single instance of permanent injury to health, much less to life. It may disagree, perhaps, in one case in a thousand, but here gives warning by a feeling of approaching dysuria, and the remedy can be at once discontinued before any real injury accrues. As to nephritis, Dr. Harkin remembers only a single case that at all approached this condition. Here a young lady suffering from phthisis had an attack of painful strangury, lasting some hours, but easily relieved by the ordinary means of stupes, hot baths, etc. Dr. Cutter, of New York, told Dr. Harkin of a case which recovered with difficulty after taking ten grains of the salt. As a contrast, Dr. Harkin mentions the case of a young man who, having been supplied with a gargle containing an ounce of the salt, through mistake drank the whole at a draught, and did not experience the least inconvenience as a consequence. Whilst therefore Dr.

Harkin does not give any credence to the exaggerated statements which have lately appeared in the medical journals, he does not think that the prescription of this remedy should pass out of the control of the profession and become a merely popular medicine, but that it should be given with caution, though without reserve under medical supervision.

WHAT IS RESORCINE?—Resorcine, says the *Journal of Chemistry* (1881, p. 52), belongs to a class of bodies called *phenols*, to which carbolic acid also belongs. In chemical composition they resemble alcohols. Pyrogallic acid is a triatomic phenol.

Resorcine was originally obtained by fusing certain resins, as gum ammoniacum or galbanum, with caustic potash, extracting it from the fused mass by acidifying with sulphuric acid and shaking with ether, and then purifying it by distillation.

Resorcine crystallizes in colorless plates or columns, and dissolves readily in water, alcohol, and ether. It melts at 104° Cent. (219° F.), and boils at 271° Cent. (520° F.), and can be obtained perfectly pure by distillation. It is claimed that it can be made in Switzerland for four dollars per kilometre (about one dollar and eighty cents per pound), but we find it quoted in German price-lists at from seven dollars and fifty cents to ten dollars per kilometre, or about twice the price of salicylic acid. To some extent the price will depend upon the demand.

Resorcine is not poisonous in moderate doses. From twenty-five to thirty grains is required to produce any marked effects. It has been found to reduce the temperature in febrile complaints, but its effect is of short duration, and unpleasant after-effects have been noticed. One of its isomers—hydrochinone—is preferred for use in fevers, the dose being smaller. The third isomer, pyrocatechine, has powerful toxic properties.

Andeer has recently investigated the properties of resorcine, and finds that it possesses the power of stopping decay. A one-per-cent. solution of chemically-pure resorcine will stop the development of fungi and mould. In every degree of concentration it coagulates albumen and precipitates it from solution, on which account it may be used as a caustic to remove unhealthy tissue. In crystals it cauterizes as powerfully as lunar caustic. In homœopathic doses resorcine will preserve ink and colors, which would otherwise mould quickly, and does not injure the color. To stop fermentation completely requires a rather strong solution of one and a half to two per cent.

Dr. Koller prophesies a great future for resorcine, which, he says, will be the disinfectant and antiseptic of the physician, the druggist, and the chemist. It must not be forgotten, however, that resorcine is too powerful a reagent to be taken internally in unlimited amount.

TREATMENT OF LABIAL OR MALIGNANT CARBUNCLE.—At the recent meeting of the American Medical Association (*New York Med. Record*, vol. i., 1881, p. 542), Dr. Charles A. Leale read a paper on this subject, in which, after giving an account of the etiology and pathology of facial carbuncle, he recommended the following treatment. Bearing in mind the arteria septi nasi, a free incision is made outward and downward along the course of the fibres of the orbicularis oris muscle, extending the cut each way until all the diseased tissue has been passed, taking care not to go through the mucous membrane lining the lip, to which the disease rarely extends; then, with a fine piece of ivory or wood covered with cotton, chemically pure nitric acid is thoroughly applied to the cut surface. This is to be pressed in with such force that every little pocket of pus is reached and the intervening membranes destroyed, which would otherwise be left to slough and to continue the septic or purulent infection. Morphia p. r. n. should be given, and whisky largely diluted with water. In some cases Dr. Leale has found it necessary to reapply the acid on the second or third day. The subsequent treatment is that of an open wound, an ointment of balsam of Peru being applied upon lint.

Dr. Leale claims that by this treatment all the little canals making the cut surface appear like a sieve are reached and the entire poisonous mass rendered inert and kept within circumscribed boundaries, and the absorbed poisons, by sustaining the system, are eliminated. In the early part of the treatment a full dose of sulphate of magnesia, largely diluted with water, is given. Generally all danger is past by the third or fourth day. The scar left is usually small. Acute mania sometimes supervenes from erysipelas or cerebral meningitis. The latter is to be treated with hypodermic injections of morphia, the former by the usual lotions, etc. The cause of failure in carbuncle and malignant pustule treated by the ordinary method is that only a portion of the diseased mass is reached, the *materies morbi* imprisoned in the minute pustules being left.

CONSTITUTIONAL EFFECT OF CHRYSOPHANIC ACID.—Prof. Charteris (*Lancet*, vol. i., 1881, p. 651) relates the case of a boy nine years of age, admitted to his wards suffering with psoriasis. He was ordered to be rubbed with the chrysophanic acid ointment (one drachm to one ounce of vaseline), and four days later the nurse informed the doctor that the boy had been sick and vomited. Circumstances pointing to the absorption of the acid as a cause of this mishap, the strength of the ointment was reduced one-half, and the little patient recovered from his psoriasis without further untoward symptoms. But the idea was suggested to Prof. Charteris's mind that the acid might have acted constitutionally, and

in several cases of psoriasis coming under his care subsequently a portion of the body affected, as an arm or leg, was wrapped up and protected from the action of the ointment which was applied elsewhere. The effect was somewhat surprising, for although the disease did not disappear so rapidly upon the protected portion of the skin, yet it did disappear during the employment of chrysophanic acid inunctions upon an entirely different part of the body.

Iodide of Ethyl in Asthma.—The *New York Medical Journal* for June, 1881, publishes three cases of asthma treated with inhalations of iodide of ethyl, with remarkable benefit. They occurred in Dr. R. M. Lawrence's service at the Boston Dispensary. Following the cases are some remarks by Dr. Lawrence, in which he says of the iodide of ethyl, "Its speedy absorption into the blood, its antispasmodic quality, and prompt reflex stimulation of the respiratory muscles, may reasonably account for its beneficial action in the asthmatic paroxysm, while its power of liquefying and detaching accumulations of mucus sufficiently explains its curative influence in chronic bronchitis. . . . Experience has confirmed my faith in its remedial worth in a large majority of cases of labored respiration (whether due to bronchial spasm or to increased mucous secretion), and also in certain obstinate cases of dyspnœa, not due to organic pulmonary or cardiac lesions, where other remedies may have proved inefficient. In a small minority of cases it has failed to afford relief." He does not recommend it as a substitute for internal medication, but rather as an adjunct thereto.

Treatment of Carbuncle by the Ether Spray.—Zimberlin (*N. Y. Med. Rec.*; from *Schmidt's Jahrb.*, No. 1, 1881) has obtained favorable results in two cases by this method. The first was a malignant pustule, which, on the fifth day, was as large as a fifty-cent piece, and surrounded by an intensely red areola. Ether spray from a Richardson's atomizer was directed upon it and its temperature reduced. On the following day the pustule was found covered with a dry scab and surrounded by a large inflammatory areola. Five days later the inflammation had subsided, the scab came away, leaving only a sensitive skin behind it. The same treatment was successful in a case of carbuncular œdema in an arm which it had already been decided to amputate.

Fluoric Acid in Bronchocele or Goitre.—Dr. Woakes (*Lancet*, vol. i., 1881, p. 497) has used fluoric acid in twenty cases of goitre, with seventeen cures and three failures resultant. The acid was given in the dose of fifteen minims to one drachm thrice daily, largely (two hundred parts) diluted with water. Injections of iodine and the coincident administration of iron and tonics aid the effect of the fluoric acid, which in some cases produces its effect with surprising rapidity.

MISCELLANY.

A New Departure in the Regulation of Prostitution.—As the question of the legal regulation of prostitution is now coming in different ways before the medical profession, the recent action of the Municipal Council of Paris in reference to it may be of interest.

In all countries where government regulation exists it has been found necessary to establish a special police for the enforcement of its regulations, and tribunals, consisting of magistrates, or officials specially designated, before whom women arrested under them are brought for the more speedy and private settlement of points growing out of the regulations, so as to avoid the slow proceedings and public scandal of such proceedings in ordinary court-rooms. This private and arbitrary mode of dealing with these women has always been one of the points most strongly objected to by the opponents of the system, and has been equally warmly upheld by its supporters, and has been adopted even in England.

At a meeting of the Municipal Council of Paris, held December 28, 1880, it was resolved, by a majority of 33 to 12, to abolish this police and their private tribunals.

The following are the resolutions, as given by the *Bulletin Continental* of January 15:

"The Council considering that the existing institution of the 'Police of Morals' violates individual liberty without accomplishing the results expected from it in its two objects, —the diminution of syphilis and the repression of offences against public order and morals, —*Resolved*,

"*First.*—That the municipal administration is requested to prepare, as speedily as possible, a plan for the establishment of gratuitous medical and pharmaceutical service for the treatment of syphilitic disease.

"*Second.*—The municipal administration is requested to prepare a system of organization which will substitute the ordinary police for the present agents of the police of morals, in everything concerning the preserving of public order in reference to prostitutes.

"*Third.*—Violations of public order and morals shall no longer be referred to arbitrary, special administration, but to the regular course of justice.

"*Fourth.*—The result of this reorganization shall be the suppression of the police of morals, to take effect on January 1, 1882."

The same change has been made, it is said, at Brussels. The fact is of especial interest, because Ricord, in a recent editorial on the subject of regulating prostitution, declares that the Bureau des Mœurs is an essential part of it. If one goes, so must the other. This remains to be seen, however.

An Æsthetic Hospital Ward.—One of the wards in the Louth County Infirmary at Dundalk has just been reopened, having been

refitted at considerable expense by Lord Clermont. The ward, which has been named after the noble lord, in recognition of his generosity on previous occasions to the institution, is thirty-seven feet long by eighteen. The ceiling is vaulted, having an opening in the centre to carry off the foul air. The walls are formed by a deep-brown skirting tile, surmounted by turquoise-blue hexagonal tiles and a moulded cutting-tile of brown and lemon color. The entire forms a dado five feet one inch in height, reaching to the window-sills. The plastering above is finished in Keen's Parian cement, of a delicate salmon color. An extremely-handsome stone chimney-piece, five feet eight inches in height, elaborately carved in the upper cross-piece, and having the words "I was sick and ye visited me" carved across the front, stands at the end of the ward. The fender is also Portland stone, the fireplace being tiled and containing a handsome dog-grate.

The Manufacture of Vinegar.—A German with the suggestive name of *Wurm* has established a factory at Breslau for the manufacture of vinegar from alcohol and water by the aid of *Mycoderma aceti*. The operation is performed in large wooden vats, provided with covers pierced with minute holes, and pipes for the renewal of the acetified alcohol and the withdrawal of the vinegar when it has reached the proper strength. The operation is begun by adding to the vat of water 2 per cent. of alcohol, 2 of ordinary vinegar, and 0.01 per cent. each of potassium, calcium, and magnesium phosphates, and 0.02 per cent. of ammonium phosphate. The temperature is kept at about 80° Fahr. The surface is then sown with a layer of *Mycoderma aceti*, and the lid fastened down. The acetification is said to proceed at more than double the usual rate. The phosphates form the natural food of the mycodermæ, and keep them in good health and condition.—*Boston Journal of Chemistry.*

Polypodium Incanum.—We have received from Dr. C. H. Mastin, of Mobile, a specimen of the above plant, with the following statement:

"It has been brought to my notice by a very intelligent lady from the interior of this State, who informs me that it is largely used by the negroes and others in the country as an emmenagogue, and that, in her observation, it is vastly more reliable than anything she has known used.

"She tells me that she knows of one plantation upon which there are a very large number of negroes residing, and that she is positive there has not been a child born there for years past, and it is well known that the females are in the habit of anticipating every menstrual period by a cup of the decoction of this plant.

"I have under my care at this time a lady from the country who has been suffering from uterine trouble and difficult menstruation, who tells me she is always quickly relieved by a teacup of the decoction of the plant which I send you."

American Medical College Association.—The late meeting of this association at Richmond was a pronounced failure, and the indications are that it was the beginning of the end of the organization. Although there were present in the city a goodly number of representatives of the medical colleges of the country, it was only after several attempts that a quorum was drummed up. The spasm of virtue which resulted in the fixing of the three courses of lectures, a year ago, has relaxed, and there seems to be a disposition to prepare for a very general collapse next year, when the three-session plan is to be enforced. The withdrawal of leading Eastern schools, and the expressed determination of others (Jefferson, for instance) to withdraw when the time arrives when the three courses are to be made a condition of membership, has had a very disheartening effect on the small Western schools. Jefferson, in spite of the demi-gods in its faculty, is, like most of the other medical schools, run for lucre; and since it has transpired that in spite of its immense facilities for clinical instruction it does not make a utilization of them a condition of graduation, lest perchance such condition might keep away students, the stand taken by its representative, Dr. Gross, at the late meeting, was not a surprise. Self-interest controls them all, and that, too, in spite of claims of devotion to the "good of the profession," "a higher medical education," and all such cant.

What will the West do under the circumstances? Remain steadfast and thus sacrifice her schools, or return to the two-course plan?

The College Association, it is to be feared, is powerless for reform, and the profession cannot compel it. Then how is it to be effected? The only bodies having the means in their hands to compel it are the State legislatures, who can divorce the teaching from the examining and licensing body; but they will require much educating before they move in the matter.—*Michigan Medical News.*

The Apothecary's Prayer.—One of the objects of interest at the recent meeting in Richmond, and which was a source of considerable amusement and banter, was a reprint of an old engraving representing a cadaverous pharmacist kneeling before a chair and offering up the following supplication:

"O mighty Æsculapius! hear a poor little man overwhelmed with misfortunes; grant, I beseech thee, to send a few small *fevers* and some obstinate *catarrhs* amongst us, or thy humble supplicant must shut up shop. And if it should please thee to throw in a few *cramps* and *agues* it would greatly help thy miserable servant; for, on the word of an

Apothecary, I have scarcely heard the music of a *mortar* this two months.

"Take notice also, I beseech thee, of the mournful condition of my neighbor CRAPE, the Undertaker, who suffers considerably by my want of practice, and loses many a job of my cutting out: enable him to bear his misfortunes with philosophy, and to look forward with new hope for the tolling of the bell.

"*Physic* those, I beseech thee, that will not encourage our profession, and *blister* their evil intentions, viz., such as their cursed newly-invented water-proof; and may all the coats be eaten by the rats that are so made. But pour down the *Balm of Gilead* on the Overseers of the village, and all the friends of *Galen*.

"May it please thee to look over my book of bad debts with an eye of compassion, and increase my neighbors' infirmities; give additional twinges to the Rector's *gout* and our worthy Curate's *rheumatism;* but above all I beseech thee to take under thy especial care the Lady of Squire HANDY, for should the child prove an heir, and thy humble servant so fortunate as to bring the young gentleman handsomely into the world, it may be the means of raising me to the highest pinnacle of fortune."

PROFESSOR PIROGOFF.—The fiftieth anniversary of the professorship of this eminent surgeon was celebrated on June 5. From the Russian journals we learn that he commenced his studies in the University of Moscow in 1824, and left in 1828, being then only seventeen years of age. After this he attended lectures in Dorpat and Heidelberg, and when only twenty years old was appointed to the chair of surgery in Dorpat, where he taught anatomy from 1836 to 1840. In the latter year he was invited to the professorship of surgery in St. Petersburg. In 1848 he served with the army in the Caucasus, and in 1853 in the Crimea. At the recent meeting of the German Surgical Congress it was resolved to send him an address on the occasion of the anniversary.

THE cable announces the death of Dr. Josef Skoda. Born in Bohemia in 1805, he graduated at the Vienna medical schools in 1831, in 1834 became second physician to the general hospital at Vienna, and became successively physician for the division of lung diseases, chief physician of the hospital, Professor of Clinics, and a member of the Vienna Academy of Sciences. Professor Skoda was one of the first to popularize the use of the stethoscope of Laennec, was a great authority on pathological anatomy and on the new methods of auscultation and percussion, and was considered the head of the new German school of diagnostics.

WHOLESALE DISTRIBUTION OF COFFINS.—In the report of the Municipal Special Committee of Hygiene of Rome, says the *Lancet*, we are told, with some unction, that, although there were only 722 deaths in the month of February, no less than 525 coffins have been distributed gratuitously to the poor.

NOTES AND QUERIES.

OBITUARY.

DR. H. LENOX HODGE, Demonstrator of Anatomy in the Medical Department of the University of Pennsylvania, died in this city, on June 9, in the forty-fifth year of his age. He was a son of the late Hugh L. Hodge, the distinguished obstetrician. Graduating in medicine from the University of Pennsylvania in 1858, he served in the army during the late war, taking part in various campaigns, and also serving in the Satterlee Hospital in West Philadelphia. In 1870 Dr. Hodge received the appointment of Demonstrator of Anatomy in the University, an office which he held until his death. Dr. Hodge was somewhat reserved in manner, and was in consequence less widely known perhaps than his abilities would have justified; but within the circle of his acquaintance he was much beloved, and his lofty personal character, public-spirited philanthropy, and devotion to the best interests of the medical school gained him the unfeigned esteem of the profession. He was the author of a number of papers on surgical subjects, an active member of the Pathological Society (of which he was at one time president), and a zealous promoter of the cause of charity organization.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM MAY 29 TO JUNE 11, 1881.

BAILY, E. I., LIEUTENANT-COLONEL AND SURGEON.—So much of Par. 1, S. O. 112, c. s., from A. G. O., as directs him to report in person to the Commanding General, Division of the Pacific, for duty as Medical Director of the Department of California, is revoked. S. O. 121, A. G. O., May 27, 1881.

Having reported at Division Headquarters, in compliance with S. O. 112, Par. 1, c. s., A. G. O., is assigned to duty as Attending Surgeon in San Francisco, relieving Surgeon C. C. Keeney. G. O. 10, Division of the Pacific and Department of California, May 31, 1881.

COUES, E., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to temporary duty as Post-Surgeon at Fort Verde, A.T. S. O. 56, Department of Arizona, May 20, 1881.

CORSON, J. K., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for one month, with permission to apply for an extension of two months. S. O. 61, Department of Arizona, May 31, 1881.

HEIZMANN, C. L., CAPTAIN AND ASSISTANT-SURGEON.—The telegraphic instructions of 22d instant to Commanding Officer, Fort Townsend, W.T., directing Assistant-Surgeon Heizmann to report at these Headquarters, confirmed. S. O. 71, Department of the Columbia, May 23, 1881.

AINSWORTH, F. C., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from temporary duty at Post of San Antonio, Texas, and assigned to duty at Fort Clark, Texas. S. O. 76, Department of Texas, May 31, 1881.

SHUFELDT, R. W., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Assigned to temporary duty in the Surgeon-General's office. S. O. 129, A. G. O., June 7, 1881.

PERLEY, H. O., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Relieved from duty in Department of Dakota, and to comply with S. O. 104, c. s., A. G. O. S. O. 97, Department of Dakota, June 6, 1881.

POWELL, J. L., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Relieved from duty with Co. "A" Twenty-Second Infantry on arrival at Fort Concho, then to proceed to Fort Stockton, Texas, and report to Post-Commander for duty as Post-Surgeon. S. O. 76, c. s., Department of Texas.

BENHAM, R. B., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Relieved from duty at Fort Abraham Lincoln, D.T., and assigned to duty at Fort Assiniboine, M.T. S. O. 97, Department of Dakota, June 6, 1881.

PHILADELPHIA, JULY 2, 1881.

ORIGINAL COMMUNICATIONS.

REMARKABLE CHANGE OF COLOR OF THE HAIR FROM LIGHT BLONDE TO NEARLY JET-BLACK IN A PATIENT WHILE UNDER TREATMENT BY PILOCARPIN—REPORT OF A CASE OF PYELO-NEPHRITIS, WITH UNUSUALLY PROLONGED ANURIA.

BY D. W. PRENTISS, A.M., M.D.,

Professor of Materia Medica and Therapeutics in the National Medical College of Washington, D.C.

MISS C., aged 25 years; a blonde, with light-blue eyes; petite figure; weight, about 100 pounds; previous health, good; occupation, school-teacher.

October, 1879.—Missed menstrual periods from this date to January, 1880, when she menstruated, and again missed until August, 1880. From October, 1879, to January, 1880, she suffered from obstinate constipation, but continued her labors at school.

Came under my care in January, 1880, for the constipation. This was very obstinate, the usual succession of purgatives failing to produce any result for a week or ten days, when the bowels would move, and immediately there would set in a profuse diarrhœa, thirty or forty watery stools in two or three days, continuing until checked by opium. For three months these alternating attacks of constipation and diarrhœa recurred, in spite of all endeavors to regulate the bowels. On several occasions there occurred large evacuations of pure jelly, from a pint to a quart at a time,—passages such as are described as sometimes being seen in membranous enteritis. This condition was finally relieved by general galvanization, applied three times a week, from thirty-six gravity battery cells. In June, 1880, there was retention of urine for thirty-six hours on two occasions, the patient from delicacy not mentioning the fact until afterwards. This was followed by an attack of acute cystitis, attended with fever, great pain in the bladder, and abundance of pus in the urine. Under appropriate treatment the acute symptoms subsided, but left behind them a chronic inflammation of the bladder. From the beginning of the cystitis until the following winter the patient was unable to pass water voluntarily, and the catheter was used regularly.

The principal treatment of the chronic cystitis was repeated daily, washing out of the bladder with a one-per-cent. solution of carbolic acid. Her condition steadily improved; but in July, 1880, there occurred an extension of the diseased process to the pelvis of the left kidney, accompanied by diminution of urine, and great pain and tenderness over the region of the kidney.

The following is the result of an examination of the urine by Dr. E. M. Schaeffer, microscopist: "July 21, 1880.—Color, pale; turbid; reaction acid; specific gravity, 1.014; no albumen (except in pus). Microscopically examined: copious deposit of muco-pus; bladder-epithelium in small amount; no triple phosphates; one pale cast seen after careful search. I do not think the pus is from the bladder in this case."

Dr. S. C. Busey saw the patient several times in consultation, and coincided in the diagnosis.

Other symptoms than those arising from the bladder and kidney, already mentioned, were alternating constipation and diarrhœa,—now easily controlled, however,—obstinate vomiting, violent headache, and sleeplessness.

Hypodermic injections of morphia relieved the headache, after many other remedies had been tried, but the morphia seemed to increase the vomiting and intensify the insomnia. After the failure of bromides to cause sleep, a trial was made of the fluid extract of Jamaica dogwood (*Piscidia erythrina*), which, when given in teaspoonful dose at bedtime, usually secured a good night's rest. The piscidia, however, was frequently rejected by the stomach, and it was further observed that it had no effect in relieving pain. When pain accompanied the insomnia the Jamaica dogwood did not cause sleep. It was further noticed that it did not cause constipation, but, on the contrary, the bowels were usually moved spontaneously the day following its administration. At one time—latter part of August, 1880—the vomiting was so constant that nothing was retained,—neither medicine nor nourishment. During this period nourishment was given by the rectum, and medicines hypodermically.

The above condition continued, with very little change, the patient being confined to bed, until November 15, when symptoms of pyelitis of the other (the right) kidney developed: great pain and tenderness in the region of the right kidney, with very marked diminution in the quantity of urine, so that for ten weeks it did not average above two ounces daily. This contained a large amount of pus, and at times had a putrid odor. At one time, for seven days (from December 16 to 23) not a drop of urine was excreted, although the catheter was introduced twice daily. Extreme uræmic symptoms developed. Dry skin, but no itching; incessant vomiting; nervous restlessness and twitchings of the limbs, flushed face, severe headache, confusion of vision, and delirium at times. This attack was tided over by the free use

of pilocarpin, and the secretion of the kidneys returned.

A record was kept of the amount of urine excreted, and this shows that from January 22, 1881, to February 2 (eleven days), not a drop of urine was passed from the bladder, the catheter still being used twice daily, and from January 22 to February 12 (twenty-one days) but thirty-six grains, or a little over two ounces of urine, were passed. Previous to December 16 the hot bath and hot pack were resorted to several times for the purpose of producing sweating, but unsuccessfully. An attempt was made to give infusion of jaborandi, both by stomach and rectum; neither was retained. Then the solid extract in gelatin-coated pills was tried by stomach, but rejected. Finally, on the 16th of December, I commenced giving hydrochlorate of pilocarpin hypodermically, in dose of one centigram (gr. ⅙). The patient was wrapped in a warm blanket, with bottles of hot water around her, previous to the administration of the hypodermic. It is to be observed that the hot bath and hot-bottle packing had been used previously without causing diaphoresis, and on two or three occasions where the hot packing was omitted the sweating from the pilocarpin was not nearly so profuse. Between the dates of December 16, 1880, and February 22, 1881, twenty-two "sweats" were administered, requiring the use of thirty-five or forty centigrams of pilocarpin. As the patient became accustomed to the medicine, it was found necessary to give two powders (two centigrams) of the pilocarpin to obtain the desired effect.

The action of the drug was carefully noted, and was as follows. Immediately, almost before the needle was withdrawn, the face and neck would flush up bright red, and dimness of vision be noticed. This was shortly followed by palpitation. In three minutes, slight nausea; eyes, nose, and mouth beginning to water, and skin showing moisture. In seven minutes, free vomiting, profuse sweating, and salivation. The action of the drug lasted from four to six hours.

An analysis of the phenomena produced results as follows:

Vomiting.—The vomiting continued throughout the "sweat" almost without intermission, and was the most distressing symptom of the ordeal. After a spell of vomiting, the patient would lie back on the pillow, hoping for a rest, when it would again return. The odor of the ejecta during February was very offensive, like decayed vegetable matter. The amount discharged in this way, which, of course, includes the saliva, was never less than two quarts, and often as much as a gallon. The patient states that she did not swallow the saliva, and insists that a large portion thus brought up came directly from the stomach. This would indicate that the pilocarpin also causes a fluid discharge from the stomach. Nausea and vomiting ceased as soon as the effect of the medicine passed off, and food was taken and retained, although previous to the "sweat" the stomach would reject everything.

Salivary glands.—In the beginning of the "sweat," water flowed freely from the eyes and nose, as well as from the mouth, but when salivation was fully established the eyes and nose ceased to discharge. The saliva was viscid and tenacious, so that to clear the mouth it was necessary to use a handkerchief. Its flow was so profuse that after thus clearing the mouth she would not have time to get a drink to quench thirst before the mouth would again be filled; so also talking connectedly was altogether prevented. Water drunk during the sweat at no time exceeded a gobletful.

Perspiration.—First noticed on forehead and neck; then the skin of the whole body, which had previously been dry and harsh, became moist. When sweating was fully established, the water ran in little streams over all parts of the body; in the face it was with difficulty kept out of the eyes. In five minutes the hair would be saturated, and, though wiped dry, it would be again soaked in a very short time. In odor the perspiration was offensive, and on several occasions had a distinctly urinous smell.

Action on heart.—Pulse became rapid in a few minutes, and when the action of the drug was fully established a thumping palpitation added to the distress, aggravated by the vomiting. This "thumping" could be heard at a distance of six feet, and continued with decreasing violence until the close of the paroxysm. The pulse ranged from 120 to 136, and was weak and compressible.

Bowels.—Just as soon as the perspiration was freely established, the bowels moved, always a large action, and on several occasions were moved more than once.

Eyes.—Pupils contracted to a small point. Sight became impaired at the first rush of blood to the face, and the dimness continued to increase, until it was impossible to distinguish objects beyond the foot of the bed. As the effects wore off, the exhaustion was extreme; pulse 130 and feeble; but there was a grateful sense of relief, and a disposition to sleep even before the sweating ceased. The head was no longer dizzy; pain in the kidneys less; stomach free from sickness, and the tongue free from coating. A quiet sleep followed, lasting several hours, from which the patient awaked refreshed and hungry.

Amount of fluid discharged during a "sweat."—This, of course, could only be estimated. Fluid from the acts of vomiting was caught in a basin, which was emptied when one-half or two-thirds full three or four times, and each time contained not less than a quart.

The blanket in which the patient was wrapped was saturated, as was also a folded sheet under the blanket. The pillow was saturated through, and the bolster beneath wet.

An experiment was made of saturating the blanket to as near as possible the same degree as when used in the sweat, and five pints of water were required. We have, then, this calculation:

By vomiting and saliva . .	7 pints.
" saturated blanket . .	5 "
" sheet, pillow, and body-clothes	2 "
	14 pints.

This seems almost incredible, but I believe the amount stated is strictly within the truth. The patient and her attendants think that the amount is understated, rather than exaggerated.

Since February 22 no pilocarpin has been administered, the symptoms having so much improved that it did not appear to be demanded. The symptoms of congestion and inflammation in the right kidney gradually disappeared, and the excretion of urine returned.

The amount of urine from that date up to the present time (June 1) has varied from a few ounces up to one and a half pints (March 3, 1881). In February the use of chloroform by inhalation was resorted to for the purpose of warding off impending convulsions. It had a very happy influence over the nervous symptoms, and appeared also to increase the amount of urine. Several times was its use followed by an increased flow of urine.

It is unnecessary, and would be tiresome, to record in detail the treatment employed to meet individual symptoms in this case. Her present condition, while it cannot be termed convalescent, is, under the circumstances, eminently satisfactory. The right kidney seems to be well; there is still pain in the left kidney, and occasionally muco-pus in small quantity in the urine. She is now able to sit up a portion of each day, and has been out to ride several times. Dr. S. C. Busey saw the patient frequently in consultation.

CHANGE IN THE COLOR OF THE HAIR.

I send four specimens of the hair.* The first, taken November, 1879, and the second, November, 1880, are as nearly as possible the same color, *a light blonde with a yellow tinge*. The third specimen, January 12, 1881, is a *chestnut-brown*, and the fourth, May 1, 1881, *almost a pure black*. The growth of the hair has also been more vigorous and is thicker than formerly. It is also much coarser, as is readily seen by a comparison of the specimens.

* These specimens received: they correspond with description.—Ed. *P. M. T.*

Dr. Emil Bessels, of the Smithsonian Institution, has made a microscopical examination of the hair, and reports that it is in every respect normal, that the change in color is due to an increase of the normal pigment, and not to a dye. The dark hair is shown to be much coarser than the light. Accompanying the change in the hair of the head there has been a corresponding change of color of hair upon other portions of the body,—not, however, to so marked a degree. In the axilla the color is about that of the specimen of January 12, 1881. There has been also a change in the color of the eyes, from a light blue to a dark blue. The use of the pilocarpin was commenced on the 16th of December, 1880. The hair was first noticed to be changing color December 28, 1880. As to subsequent changes the specimens speak for themselves.

The important question here presenting itself is, Was this change of color due to the pilocarpin or to some other cause? I have not seen such an effect noted as the result of jaborandi, yet there seems to be in this case no other reasonable explanation. The disease can hardly be charged with it, for uræmia is of too common occurrence for such an effect to have escaped observation, even though it were only occasional. Nor have we any reason to suppose that the change was due to the combined effect of uræmia and the jaborandi.

The change had not commenced in the latter part of November, 1880, when specimen No. 2 was taken. The pilocarpin treatment was begun on the 16th of December, 1880. Twelve days later it was first noticed that the hair was of a darker color, and from that date the alteration was rapidly progressive.

It is well established that jaborandi increases the nutrition of the hair, stimulates its growth, and renders it thicker. Changes in the color of the hair are of frequent occurrence as a result of sudden violent emotions, such as fright, great grief, or even sudden joy: the change, however, is always from dark to white. But a rapid change from light to black I have seen nowhere recorded. The flaxen hair of childhood becomes gradually darker during adolescence; but usually no further change takes place after adult life is reached.

After protracted illness, such as typhoid fever, it frequently happens that the old

hair falls out and the new growth as it appears is of a darker color. The change, however, does not take place in the old hair. In mammals and birds, however, we have numerous instances of changes of color in both directions,—from dark to light, and the opposite, this change being due not merely to new growth, but to an actual alteration of the color of existing hairs or feathers.

Dr. Weinland investigated this subject from museum specimens, and was led to the conclusion that change of color was due to increase or diminution of oily matter. The fresh feathers were examined from the breast of a merganser, and the red color found to be due to numerous lacunæ filled with a reddish oil-like fluid. When dried, the feathers bleached, and it was then found that the lacunæ were filled with air only.

According to this theory, an increase of nutrition would have a tendency to darken the hair, and *vice versâ*. This is borne out by the fact that dark or black hair is almost always thicker and coarser than light hair, and also by the change in hair to gray and white as age advances and the processes of nutrition become enfeebled. So also when the hair is thin, shaving the scalp will generally cause it to become thicker, firmer, and darker. This can only be through the influence of nutrition.

It gives us a clue also to the *modus operandi* of the change in the case here reported, for we know by clinical experience that pilocarpin increases the nutrition of hair, as shown by its augmented growth.

We have therefore in this case both positive and negative evidence in support of the view that the change in the color of this patient's hair was due to the pilocarpin.

This case has been one of unusual interest, and in closing the report it will be profitable to recapitulate briefly the points worthy of note.

1. The prolonged period of total suppression of urine. In one instance this extended over eleven days, and for twenty-one days the anuria might have been almost considered total, the daily average being less than one teaspoonful.

2. The value of the pilocarpin in eliminating urea from the system and averting the consequences of uræmic poisoning. The usefulness of this drug in uræmia and in the various forms of dropsy is coming to be well known, but it seldom happens that its beneficial effects are so strongly marked as in this case. The uræmia was extreme, and the case at one time so apparently hopeless that it became a serious question whether we were justified in pursuing a course of treatment so distressing to the patient. Dr. Bartholow says of pyelo-nephritis, "When uræmic symptoms occur, the duration is measured by weeks, and but one termination is possible." (Pract. Med., p. 469.)

In this case much of the success of the treatment was undoubtedly due to the patient herself. She is of a bright, sunny disposition, and has been upheld throughout her illness by a positive determination *not to die*, and she seconded most faithfully the efforts of her physician in her behalf.

3. The amount of fluid eliminated during a "sweat." I have hesitated to state the amount (fourteen pounds), which is about one-seventh of the body-weight, because it seems almost incredible; but a careful reconsideration satisfies me that the statement is not exaggerated. I think it probable that the amount was increased by the hot-bottle pack.

4. The effects produced in this case by the pilocarpin upon the stomach and bowels would indicate that it excites a watery discharge from their mucous membranes as well as from the skin and salivary glands.

5. The hypodermic use of pilocarpin. The hydrochlorate is perfectly soluble, and its use under the skin is unattended with pain or irritation. Its action hypodermically is more prompt and the effects are sooner over than when it is administered by the stomach. It has been recently stated that the jaborandi contains another alkaloid, jaborin, which is antagonistic to pilocarpin. If this be true, it is decidedly preferable to use the pilocarpin rather than the leaves.

6. The change in the color of the hair. If I have properly attributed this to the action of the medicine, it would seem to add another to the marvellous effects of this agent upon the human system.

7. There was no dropsy in this case. In two other cases of pyelo-nephritis occurring in my practice which resulted fatally there was no dropsy. Uræmia, or rather anuria, is not sufficient to cause dropsy, but combined with a drain of albumen (albuminuria) dropsy soon results.

AIDS TO DIAGNOSIS IN NASAL DISEASE.

Read before the Philadelphia County Medical Society, April 13, 1881,

BY HARRISON ALLEN, M.D.

IN making a diagnosis of nasal disease considerable difficulty is acknowledged. The nasal chambers are intricate in their outlines, the apertures permitting inspection are small, and the various structures seen therethrough are foreshortened to the eye.

TO EXAMINE THE NASAL CHAMBERS.

The following rules have been framed with the object in view of simplifying the examination and to properly interpret what is seen.

1st. Bring the shoulders forward and throw the head far back. Insert the speculum. The under surface of the middle turbinated bone will be seen at its anterior part, provided no undue narrowing of the chamber exists. In the same position, inspect the chink between the anterior end of the middle turbinated bone and the outer wall of the vestibule.* Make such use of the probe as may be indicated to ascertain the condition of the mucous membrane, and the nature of the points of contact (if such should exist) between the median and lateral walls.

2d. The shoulders to be in the same position as in the preceding. The speculum being in place, bring the head slightly forward. The middle turbinated bone now passes from the field, and the ethmo-vomerine sutural projection, if such exists, becomes visible. When it is present, the posterior portion of the middle turbinated bone, the ethmo-vomerine projection, and the superior curved portion of the inferior turbinated bone are occasionally seen to be in contact with one another. No obstruction to breathing need follow upon this arrangement, provided the inferior portion of the chamber remains open. In other examples, the parts just mentioned are separated from one another when a black curvilinear chink exists between the inferior turbinated bone and the septum. If this chink does not exist, by reason of the pressure of the sides against one another, distress is very apt to be acknowledged. During treatment the chink can be defined at the time the patient reports improvement. In yet another group of nasal chambers the parts in question are remote from one another, and the lower portion of the wall of the sphenoid sinus is seen, together with the upper portion of the choana.

3d. The shoulders still being forward, the head is brought in a horizontal position. The space between the sides of the inferior turbinated bone and the septum is now seen through the speculum. If the chamber is capacious, and the anterior osseous aperture large, the plane of the opening of the inferior meatus is visible and situate about half-way up the outer side of the field. If, however, the parts are everywhere contracted, the plane of the inferior meatus-orifice is not seen, or, if it is seen, its upper portion only is discernible.

Such inspection as is practicable of the middle meatus can be made either in the second or third positions.

4th. Preserving the forward position of the shoulders, as before, bring the head well down on the chest. Insert a small-calibred speculum and push it as far inward to the lower portion of the anterior osseous aperture as is possible. The floor of the nasal chamber is now seen at its anterior part. The chink between the anterior end of the inferior turbinated bone and the floor, and the floor of the vestibule itself, are all visible. This field is frequently obstructed by an outgrowth from the septum, either maxillary or vomerine in nature. Should hypertrophy of the inferior turbinated bone exist, the chink between the bone and the floor of the nose is obliterated.

TO DETECT THE SIGNIFICANCE OF TRACTION-BANDS.

The history of recurrent obstruction from angiose turgescence can be confirmed by the presence of cobweb-like threads of mucus stretching across the chamber from the lateral to the median wall. The following explanation is ventured upon: the surfaces once in contact have separated, but give evidence of their former position by these traction-bands.

TO DETECT OBSTRUCTION.

Close the mouth and the nose of the opposite side; then bring the shoulders forward and throw the head back. Request the patient to breathe. If the sound is sniffling, especially if the act be associated with adduction of the lateral wall of the external nose above the wing, obstruction exists. Then insert Zaufal's speculum in the premaxillary portion of the nose. Re-

* By vestibule is meant the interior of the external nose.

peat the breathing-test. If the sniffling is now relieved, obstruction of the vestibule or the premaxillary region may be diagnosed. Should the sniffling persist, push the speculum into the maxillary portion, and in succession to the palatal, renewing the test of breathing in each instance; or, the small rubber speculum being in position, raise suspicious folds of mucous membrane with a probe and request the patient to breathe. Such improvement of breathing after thus pressing aside the turgescent folds furnishes a clue to the nature and location of the obstruction. The presence of mucus in the nasal chamber can be detected by its motion forward and backward during respiration, when conducted in the manner above described.

TO PREPARE A NASAL CHAMBER FOR EXAMINATION WHERE GREAT NARROWING EXISTS FROM CONGESTION OF THE MEMBRANES.

Apply a primary current of electricity from two to six cells. The cathode should be placed over the cheek below the infra-orbital foramen, and the anode on the nape of the neck or at the mastoid fossa. After the current has passed for five minutes the patient will announce the fact that the obstruction is relieved. Inspection can now be made of the deeper parts with ease. Should the obstruction not yield to this test, a diagnosis of infiltration of the tissues may be made. An excessively angiose condition of the membranes accompanied with hyperæsthesia is rarely seen, which will not yield to the current. These applications are not only aids to diagnosis, but are often in themselves curative. Obstruction not due to turgescence or infiltration may be proved to be osseous by the probe.

TO DETERMINE THE CONDITION OF THE MEMBRANES BY THE REFLECTION OF LIGHT THEREFROM.

A moist surface yields a broad, brilliant reflection. A dry one yields a diffused, dull reflection, which at the same time that it is diffused is broken up into minute points of light.

A mammillated moist surface will throw off multiple reflections, but a uniformly convex surface will throw a single large pencil of light.

TO EXAMINE THE CELLS OF THE NASAL MUCOUS MEMBRANE.

A double angulated probe passed into the normally constituted space between the lower turbinated bone and the septum, and drawn forward at the same time that it is pressed firmly against one of the sides, can be withdrawn, bringing with it a drop of the mucus of the region through which it has passed. This drop, when examined with the microscope, will show characteristic epithelial cells, with active cilia. The cells are deformed in outline, without cilia, and otherwise changed, in mild forms of atrophic degeneration of the turbinated bones,—deformed, without cilia, and excessively granulated in the infiltration of syphilis,—or absent in angiose turgescence and in advanced forms of atrophic degeneration. Angiose turgescence exists in hay fever and some forms of catarrh, associated with hyperæsthesia, simulating hay fever. In such diseases the cells are not easily detached, and cannot be found in the mucus.

For clinical purposes the nasal region may be divided into the premaxillary, the maxillary, and the palatal portion. If sections be made by sawing the skull in frontal (transverse vertical) planes at the lines of sutural union on the hard palate, viz., between the premaxillæ and the maxillæ, and between the maxillæ and the palatal bones, subdivisions of the nasal chamber are secured which embrace more or less natural regions. The premaxillary portion includes the vestibule and the nasal chambers proper, so far as to embrace the anterior ends of the turbinated bones. The upward extension of the section would answer to the anterior border of the anterior cerebral fossa. The maxillary portion includes the turbinated bones within the point last mentioned and the hinder ends. The palatal portion includes the hinder ends of the turbinated bones and the region extending thence to the posterior nares.

SEQUEL TO THE CASE OF ARSENICAL PARALYSIS

DETAILED IN A CLINICAL LECTURE ON ARSENICAL PARALYSIS PUBLISHED IN THE PHILADELPHIA MEDICAL TIMES, MARCH 26, 1881,

BY J. M. DA COSTA, M.D.

JUDGING from the communications that have reached me, the lecture on arsenical paralysis and the case therein reported have proved of interest to many physicians. I believe, therefore, that it may not be unacceptable to record the sequel to the case. It is easily told. It was one of steady improvement, suspended

for a time by the ulceration around the toes, particularly the great toes, which proved to be due to ingrowing toe-nails. When these were remedied, the patient began to walk around again, though the enforced confinement which the discomfort in his locomotion had entailed put him back for three weeks, and on getting up his walking was less easy than formerly, owing to a contraction of the tendo Achillis of both legs; but this yielded to massage, and the favorable progress of his symptoms was unchecked by further mishaps. The erythematous rash on the soles of the feet lasted but a few days, and passed off when the acetate of potassium was substituted for the iodide, and under an ointment of oxide of zinc. With but slight variations, his treatment consisted, during the last months in the hospital, of iodide of potassium and cod-liver oil; faradization and massage were also used. There never was a drawback in the amelioration of his mental condition after it had once fairly set in; the state of his legs improved up to the point that he could walk around with a cane, but there was still considerable palsy, especially in the muscles of the anterior tibio-fibular region, and their electro-muscular contractility remained much impaired. It was in this condition, but in very good general health, that he left the hospital on the 6th of May. I will add that during the period in which I had charge of him, and subsequently while under the care of my colleagues, he never had the least sign that pointed to a syphilitic infection; indeed, neither sore throat, nor enlargement of the post-cervical or inguinal glands, nor falling of the hair, nor node, nor bone-pain, nor substernal tenderness, nor specific eruption, was at any time to be found; enabling the repetition of the statement made in the lecture-room, that he had never had secondary symptoms.

In this connection, too, it may be proper to add that a fuller knowledge of the case makes me question whether he ever had syphilis at all, even of a non-infecting kind. The history of syphilis was obtained on his admission to the hospital, but, owing to his wretched mental condition, would not have been accepted at all if it had not been corroborated by his friends. Yet, as he regained his mental health, he repeatedly said that he had been told, while under care outside, that he would not have syphilitic symptoms; and on inquiry from Dr. Walter F. Altee, who had attended him, the fact was elicited that it was in May, 1880, and not in September of the preceding year, that the patient had had a violent gonorrhœa, followed by balanitis and a few superficial ulcers on the glans, and by a suppurating bubo in the left groin. This distinguished surgeon did not believe the phenomena to be syphilitic, and not under any circumstances those of an infecting chancre: hence his remark to him that constitutional symptoms would not ensue. It may not be without interest to state that Dr. Atlee has seen him repeatedly take large pinches of arsenic—probably from five to ten grains—out of a paper carried in his vest-pocket.

On another point, too, of the early part of the case, I now possess additional information. While still under the influence of the acute poisoning, and before I saw him, an erythematous eruption was perceived on the chest and abdomen, as mentioned in the published lecture-notes. I had supposed it to be one of the forms of eruption which we all know occur at times in arsenical poisoning; and this it evidently was. I have acertained it from those who saw it to have been an erythematous flush chiefly occupying the front of the chest, here and there slightly raised, as if the skin were swollen, having on the outskirts of the large patches smaller spots like roseola, but all of vividly red color, and occurring in three successive outbreaks, the skin becoming of normal appearance between them. The longest of these outbreaks was the first; it lasted six days, was attended with considerable itching, or, rather, burning, and followed by slight desquamation. The other outbreaks were from three to four days, and presented the same phenomena, although not quite so marked. The patient was not at the time taking iodide of potassium, or, indeed, any specific treatment. The character of the eruption impresses me very much like the disseminated patches in connection with a papular eruption described by Imbert-Gourbeyre as due to arsenic.

Re-examinations of the urine never showed anything abnormal. I regret that it was not examined for arsenic. But I do not think that, except early in the case, arsenic would have been found in the urine. I learn from a quite recently published instance of arsenic-poisoning followed by paralysis, by Seeligmüller, in the

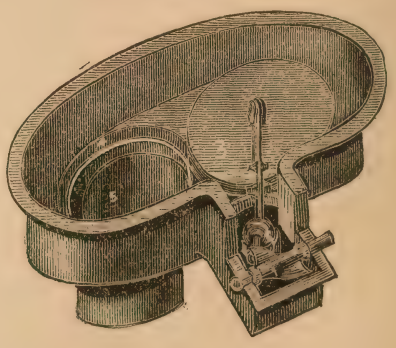
Deutsche Medicinische Wochenschrift, April 16, 1881, that even in a very pronounced instance it may not be detected. The gums always showed the same appearance; they never presented any metallic line, but always a burnished, porcelain-like look, similar to the gums of false teeth.

Since the patient has left the hospital, I have seen him several times, once within a few days. He has stopped the iodide for over a month, and is taking tonics, chiefly of pyrophosphate of iron and of strychnia. He is constantly improving in strength, and walks a couple of miles daily. He has pain in his feet after walking, and for a time in his limbs, but only then if the exercise has been too severe for him. He walks aided by his cane, although not dependent on it, and with the shuffling gait of a paraplegic. He can stand and walk with his eyes shut, although with greater difficulty than when they are open. It is not likely that he will improve very much more: he has probably almost reached the highest point of his recovery.

A NEW HYGIENIC APPLIANCE.

Remarks before the Philadelphia County Medical Society, Wednesday, March 23, 1881,

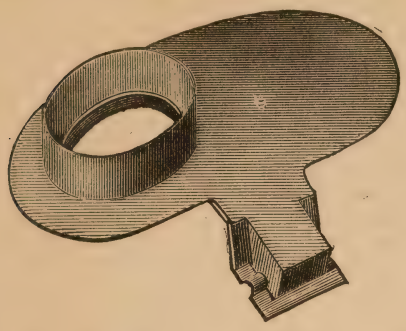
BY BENJAMIN LEE, A.M., M.D.



AFTER the eloquent lecture from Dr. Wood to which we have been listening, and the extremely interesting discussion which has followed it, I fear that to many of you the descent to the consideration of a water-closet will seem the step from the sublime to the ridiculous. With the Roman philosopher, however, I say, "*Humani nihil a me alienum puto.*" I hold nothing which concerns the comfort and welfare of the human being foreign to the province of the physician.

Independently of leakage, sewer-gas enters our homes in three ways. The water-seal of the trap of the water-closet, stationary wash-stand or wash-tub, or bath, as the case may be, may become inefficient, 1st, in consequence of the water falling below the protective level from evaporation, when the appliance is for some time unused; 2d, from what is called siphoning,—that is, the production of a vacuum in the soil-pipe by the sudden rush of water from a closet on a higher level, which sucks out the water from the trap; and finally, in consequence of saturation,—that is to say, the water slowly absorbs the gas in contact with its sewer surface until it becomes entirely saturated: as soon as this has taken place it begins to give it off at its closet or basin surface as rapidly as it receives it at the other.

This last is perhaps the most dangerous, because the most insidious, form in which the poison finds access to our homes. It is that which takes place all through the night from the wash-stand which is by our bedside, or the bath-tub in the adjoining dressing-room, while the water-closet is more apt to be in a distant part of the house and quite distinct from sleeping-apartments. The appliance to which I now call your attention affords a complete remedy for this evil as long as it is in position. During the brief time in which the closet is in use it is not operative; our protection then must be in the water-trap, which still exists below this, and in ventilation. And I would here briefly say, in passing, that thorough ventilation is a *sine quâ non* in sanitary plumbing. No system of plumbing should now be introduced into any house which does not include a ventilating shaft as large as the soil-pipe, having its top above the roof of the house, and running, if possible, along the smoke-stack, so that the heat thus communicated may create an upward draft.



With the aid of this model I think you will have no difficulty in understanding the contrivance, which is simple and not easily disarranged, although, at the same time, a very beautiful piece of mechanism.

The hole which you observe in this metal casting is just the size of the top of

the soil-pipe, and is continuous with it, being below the hopper and above the water-trap. Around the edge of this hole and on the upper surface of the casting is a trough about three-fourths of an inch deep. This movable cap which I now

show you is provided with a flange on its under surface exactly corresponding to the

trough. Now, it will readily be understood that so long as this flanged cap sits in a fluid in the trough, provided this fluid is impervious to gases, so long is the passage of gas beyond it a physical impossibility. Such a fluid we find in mercury. It cannot evaporate; it is too heavy to be siphoned out; and it does not absorb gases. Its loss from oxidation is so slight as to be almost imperceptible. This cap is moved on and off from the opening of the soil-pipe by means of an ingenious contrivance known as "Spratt's Movement," in which the opposite end of the lever which is attached to its upper surface articulates, as you see, by means of this spherical head with a deep spiral groove on a horizontal shaft. This shaft is attached by a sort of crank-rod to the cover of the seat. Now, as I lift the cover I also lift the cap and throw it to one side in a chamber provided for the purpose; as I shut down the cover I replace the cap, and the seal is perfect. This appliance can be adjusted to any water-closet of whatever description. In case of there not being sufficient thickness of joist to allow of its being set under the floor, the seat must be proportionately raised,—say about three inches. This slight inconvenience can be met by placing a low step in front of the seat.

So much for the water-closet. I now show you the seal for the wash-stand and similar arrangements. It is made of glass, so that if out of order the fact can be detected in a moment. It consists of a cylindrical glass reservoir closed at the top and admitting the waste-pipe through its bottom. The waste-pipe ascends to within about two-fifths of the distance from the top, terminating in a free extremity; over this free extremity sits quite loosely a glass cup like a small tumbler turned upside-down. At about the level of the free extremity of the waste-pipe there is a hole in the side of the reservoir for the escape of the water.

As in the case of the water-closet seal, mercury is again used as the sealing fluid. Here it covers the bottom of the reservoir to a depth of half an inch or more. The working of the appliance is as follows. When a stream of water enters from below, it lifts the inverted glass cup out of the mercury, as I now lift it with this penholder. Flowing out under the rim of the cup and over the surface of the mercury, it fills the reservoir and escapes at the opening in its side. The moment the current ceases, the cup falls back into its place, and should there be any reflux of gas it exerts its pressure on the top of the cup, thus firmly holding it in the mercury and adding to the security of the seal.*

STRANGULATED FEMORAL HERNIA—OPERATION—BOWEL RUPTURED—DEATH.

BY CHARLES W. DULLES, M.D.,

Surgical Registrar to the Hospital of the University of Pennsylvania.

ON May 14, 1880, I was called to see Mrs. A., aged 87 years, an inmate of the Philadelphia Home for Incurables. She had been admitted to the Home more than two years before with an incurable chronic rheumatism and chronic bronchitis. Her hands presented a remarkable and extreme picture of the effects of arthritis deformans, the fingers being abducted and flexed until they overlapped each other like the claws of a fowl, and it was necessary for her to have a piece of linen pushed under them to prevent excoriation of their skin and that of the palms.

When called to see her, her case had not been deemed very urgent by her care-takers at the Home. She had, however, had persistent constipation and vomiting for about thirty-six hours, and complained of colicky pains in the abdomen. On examining her, I found that she had a strangulated left femoral hernia. The account I obtained of the condition of the parts previous to this attack was uncertain, but left no doubt in my mind that the hernia was comparatively recent. The tumor was red, inflamed, œdematous, and very pain-

* These appliances are designated as the "Evans Sewer-Gas Mercury Seal," and may be inspected at 239 South Sixth Street.

ful, half spindle-shaped, about three inches long and half an inch in elevation, and lying just below and parallel with Poupart's ligament. The persistent vomiting, the pains, and my inability to reduce the tumor by moderate taxis, brought me to the conclusion that the case demanded operation. I then secured the advice and co-operation of Drs. Keen and Judd, and Messrs. Griffith and Jayne,—office students of the former,—and, ether having been administered, made another effort to reduce the bowel, seconded by Dr. Keen, and, this failing, proceeded to operate, under the carbolic acid spray, in the method of Lister. The tissues were divided down to the sac, and an attempt made to reduce *en masse*. In doing this the sac was burst, and a very small quantity of fluid with a fecal odor escaped. Very soon, however, the bowel receded within the abdomen, and the wound was cleaned, sponged out, and closed. A few strands of carbolized silk were laid below the sutures, so as to depend from the lower angle and effect drainage. Over all were placed the antiseptic layers recommended by Lister. The ether was suspended, and brandy, milk, and lime-water ordered to be given by the mouth at short intervals.

The vomiting did not return after the operation, but the patient never rallied. She recovered consciousness, and had little suffering, but steadily sank, until she died the next afternoon, twenty hours after the operation.

The next day a post-mortem examination was made. On opening the abdomen, no evidence whatever of recent peritonitis was found, except about the internal opening of the femoral canal, to which a transverse coil of the ileum and a fold of the omentum were slightly adherent. On pulling the intestine away, it was seen that a knuckle about an inch and a half long had lain across the opening of the femoral canal, into which a part of one side only had been pushed and tightly strangulated in such a manner as almost entirely to occlude its lumen previous to the operation. The hernial portion was discolored and gangrenous-looking, and in it there was a small opening, which Dr. Keen thought to have been made in separating it from its adhesions at the autopsy.

I removed a portion of the intestine about three inches long, and took it away for subsequent and more detailed examination.

On making this, I found the bulging portion that had descended and been strangulated was in parts thick and congested; at its lower curve, however, it was very much thinned in several places, and had two small openings. One of these may well have occurred at the autopsy in breaking up the recent peritonitic adhesions; but the other, I am inclined to think, had occurred before the operation, because its edges were too abrupt and too well defined to seem to me like tears. The impression that suggested itself to me when operating, on account of the odor that was emitted when the sac gave way,—namely, that the bowel had been loaded and burst by the effort to reduce it,—remains with me. Yet, as already stated, there were found at the autopsy no evidences of the escape of any fecal matter into the abdominal cavity, nor any inflammation,—only a little lymph, causing the bowel to adhere to the edges of the femoral ring. The patient's death seems to have been due to the fact that her great age and her chronic invalidism made it impossible for her to survive the depression due to thirty-six hours' strangulation of the intestine, with the added strain of a grave surgical operation.

April, 1881.—The specimen showing the rents in the intestine I gave to Dr. Formad, who made sections of them and examined them microscopically. He informs me that the openings presented no evidence of ulceration, but were undoubtedly traumatic, being simple ragged solutions of continuity.

I am therefore convinced that I was right in believing that the bowel was burst during the operation, in the effort to reduce it after the sac had been opened. No very great force was used, but certainly too much for the resistance of the thin, old intestine.

Some years ago I assisted at the first operation for strangulated hernia that I ever saw, and I well remember the solicitude with which I watched the force used by the operator in reducing the gut. At a later period I was called, in the ambulance service of the Philadelphia Hospital, to a man who had been stabbed in the abdomen, and from whose belly a few inches of intestine had protruded. What I considered reasonable efforts to reduce it being unsuccessful at the place where I found him, I kept the bowel wet and transported him to the hospital. Here he fell into the hands of another resident surgeon, whose violent efforts I thought would surely burst the bowel; but, to my surprise and relief, they only sent it back to its proper place, and the patient made a good recovery.

These cases gave me an idea of the toughness of the bowel which I could not otherwise have entertained. They did not lead me to employ any unusual force in the operation I have just narrated, but they heightened my surprise at its result. The moral, it appears to me, is that in an old person scarcely any force can be called safe, and that the freest possible opening should be made before any attempt to reduce a hernia that has been strangulated.

NOTES OF HOSPITAL PRACTICE.

LOUISVILLE CITY HOSPITAL.

CLINICAL LECTURE BY WM. H. WATHEN, M.D., OF THE KENTUCKY SCHOOL OF MEDICINE.

Reported by A. H. Kelch, M.D.

LACERATION OF THE CERVIX UTERI.

GENTLEMEN,—This woman says she is 28 years old, the mother of four children, and that she has had good health until the birth of her last child, four years ago. Since then she has never been well. Her bowels are constipated, her appetite poor, her digestion and assimilation much impaired. She is pale, anæmic, and extremely nervous; her menses have not returned since parturition, but were always regular and normal before. She has been confined to bed most of the time, and has seldom been able to take active exercise. She has had pain and soreness in the iliac regions (worse in the left), a sense of weight and pressure in the pelvis, and a constant, profuse, and tenacious leucorrhœal discharge. She has sympathetic disturbance of the heart, and complains of pains in her head, back, and limbs.

These subjective symptoms are diagnostic of some uterine trouble, but are common to many uterine diseases, and are pathognomonic of none. They do not enable us to arrive at any positive diagnosis, but indicate the necessity for a physical examination by which we may avail ourselves of the more reliable objective symptoms. In a digital examination I find the uterus prolapsed and apparently retroverted, and the cervix lacerated on the left side up to the vaginal junction. . . . Having exposed the cervix with a bivalve speculum, we see that both lips, particularly the posterior, are enlarged, and that the mucous membrane in and around the os is inflamed. The laceration is seen to be nearly healed over. The sound shows that the uterus is completely retroverted, and it causes pain when I press the point against its walls. The cavity measures three and a half inches, and since withdrawing the sound there is some bleeding from the os. There are no adhesions binding the uterus down, and it can be placed in its normal position by rotating the sound. We now recognize laceration of the cervix, retroversion, and chronic endometritis; but we must know more about the cause and results of these troubles and the relation one bears to another before we are prepared to adopt a plan of treatment. From our own experience and the researches of Emmett, Goodell, and other authorities on this subject, we conclude that the cervix was lacerated at the last labor, and failure to unite prevented healthy involution, causing permanent enlargement of the uterus, with its natural consequences, inflammation and displacement. This laceration is easily recognized by the finger and by sight; but there are cases where the diagnosis is made with difficulty even by experienced gynæcologists and not at all by the general practitioner, who often knows very little about this subject and treats such patients with strong caustic applications for simple cancroid or cancerous ulceration of the cervix. That laceration does frequently occur in labor, and often remains as a permanent lesion, is now pretty generally recognized and understood in gynæcological circles. Emmett discovered the character and the treatment of this lesion in 1862, and published his first paper on the subject in 1869. Since then, in his papers and in his work on gynæcology, he has told us about all that is known on the subject. Dr. William Goodell and many other writers have added valuable papers.

This injury is caused by labor, and may occur in any part of the rim of the os uteri, but is generally on the left side, which is explained by the fact that the occiput is usually in that position. The lesion may extend only partly through the walls of the cervix, or through its entire thickness, and sometimes from the os to and above the vaginal attachment. It may be lateral or bilateral, in either lip or through the conjugate diameter. The lacerations may also be numerous and give the cervix a stellate appearance. There is, perhaps, some laceration in nearly all cases of labor, particularly in the primipara, but it is usually so insignificant that it causes no inconvenience, and disappears in the course of a few weeks. In those cases where the laceration is extensive it is generally the result of rapid labor, early rupture of the membranes, the administration of ergot, and the use of forceps before the cervix is fully dilated. It may also be caused by a tedious and protracted labor, or by an attempt to push the anterior rim of the cervix over the presenting parts.

Rigidity of the os from any cause would predispose to this danger. Hemorrhage is the only immediate symptom that attends the lesion. The cervix is so bruised and swollen that the rent cannot easily be discovered soon after labor: however, if there is constant bleeding after the uterus is well contracted, such an injury may be suspected. Although the rent may extend above the vaginal attachment, the bleeding is seldom alarming, for the utero-cervical artery is so elastic and tortuous and so loosely connected with the parts that it will stretch and thus escape being ruptured. If the laceration is in such a position that the edges are kept in apposition, there will often be union by first intention or adhesion. If the rent is in either lip, or through both, it will generally unite, as the line of division is within the axis of the greatest uterine mobility, and the lateral walls of the vagina will press the edges together. But if the laceration is lateral or bilateral, the division is transverse to the axis of motion, and the vaginal walls give no support. Besides, when the woman gets out of bed the uterus is larger, and its downward pressure causes the vaginal walls to separate the lips and keep them permanently everted so that union is impossible. Even if union does occur while the woman is in bed, the edges will be likely to separate when she assumes the erect posture. If the rent extends above the vaginal attachment or fails to unite by adhesion, there is frequently some pelvic cellulitis or peritonitis developed from the third to the fifth day, the symptoms of which are generally well marked, but may be so masked that the complication would not be detected without a careful physical examination. In such cases convalescence is slow, and the uterus is often permanently displaced and bound down by adhesions. In any event, it requires a long time for absorption of the inflammatory products, and the woman may be a cripple for life.

The triple process of involution—contraction, conversion of superfluous tissue into granular fat, and absorption—is interrupted, and the uterus remains permanently enlarged, causing displacement and inflammation, with a profuse leucorrhœal discharge, and the various local and reflex disturbances that accompany these disorders. The injury may cause but little annoyance until menstruation reappears, for during lactation the blood is attracted to the mammary glands and there is no periodic congestion of the uterus and pelvic organs.

When the laceration has healed over, there may be no symptom that attracts attention unless a nerve be imprisoned and pinched in dense cicatricial tissue and serves as a constant source of irritation, keeping the patient fretful and nervous; failing to heal, the lips become everted, exposing the intra-cervical mucous membrane, which by constant attrition against the vaginal walls and by direct exposure to violence in coition gradually loses its epithelium and is eroded or ulcerated. There may also be follicular, villous, or coxcomb ulceration, and the cervix occasionally has the appearance of the cauliflower excrescence of epithelioma. Subinvolution causes retroversion and prolapsus, puts the uterus within the axis of the vagina, and subjects the cervix to direct injury in coition. The woman becomes a confirmed invalid, and is generally sterile, but may conceive in the worst forms: if so, there is a tendency to abortion, on account of the constant irritation of the cervix and its weak retentive powers. The laceration may be so extensive and the mucous membrane so everted that the canal is exposed to the internal os.

Writers variously estimate the frequency of this injury in all uterine diseases at from five to forty per cent. I have met with a great many of these cases in private and hospital practice, and would put the estimate at fifteen per cent. There is no difficulty in making the diagnosis by the finger or by sight when the laceration has healed over. If the rent is bilateral the finger will detect a transverse fissure, and if lateral a notch in the side. With the cervix exposed the transverse fissure or the notch may be seen. But when the cervical mucous membrane is eroded or ulcerated the diagnosis may be difficult, and the true nature of the malady be entirely overlooked. This condition, or follicular enlargement, frequently causes an ectropium like that of the conjunctiva, and conceals the rent so perfectly that it cannot be felt or seen. But if the woman's bad health dates from the time of her last labor, and she has a profuse and tough leucorrhœal discharge with the cervix apparently eroded or inflamed around the os, which fails to improve under treatment or heals

over and seems to be well but again loses its epithelium when she begins taking exercise or having connection, you may suspect laceration. Though the everted mucous membrane often fills up the cavity between the curled-over lips, making it impossible to detect the rent by the finger or by the sight alone, still with proper care the diagnosis can be accurately made.

Place the woman in any of the recognized positions, but preferably on the knees and elbows, and dilate the vagina with a duck-bill or bivalve speculum. Then with a tenaculum introduced in the vaginal surface of each lip, attempt to bring them together, and the everted mucous membrane will gradually roll into the cervical canal, and finally nearly or entirely disappear, and what was supposed to be the external os is now found to be the opening into the cervical canal upon a level with the fork of the laceration, and is from one-quarter of an inch to an inch above the real os tincæ. I prefer the knee-elbow position because it removes abdominal pressure from off the pelvic viscera, and allows the uterus by gravitation to ascend higher into the cavity, thus enabling us to force more easily the everted membrane into the canal. The rent can now be plainly seen, and what appeared to be an ulceration around the os was the exposed and abraded mucous membrane of the cervical canal.

While many women complain of the symptoms I have mentioned, there are others who suffer very little inconvenience. Just as in some other forms of uterine diseases, what makes one woman a confirmed invalid causes another hardly any annoyance. The peculiar constitution and habits of the woman have a great deal to do with the impression the injury makes upon her system.

The treatment of laceration of the cervix uteri may be divided into the immediate and subsequent treatment; that is, the treatment indicated if the injury be discovered soon after it occurred, and when the woman applies for relief from the symptoms that secondarily result from this lesion. If the laceration is detected immediately after labor, and there is much bleeding, it should be controlled by ice, hot-water injections, injection of a saturated solution of alum, or any local hæmostatic that will not prevent immediate union. If hemorrhage is profuse and it is not arrested by this treatment, introduce a silver suture to unite the edges of the rent. Wash out the vagina once or twice daily with warm or hot water, and, if there is an offensive discharge, add some disinfectant, such as carbolic acid or permanganate of potash. If the edges do not unite, this treatment will generally cause the rent to heal over and make involution more perfect, thereby lessening the dangers of future trouble. These are the measures which constitute the immediate treatment, which, in the event of failure to accomplish the purpose towards which they are directed, are to be followed by the measures which I shall take at our next meeting to establish a complete and permanent cure.

(To be continued.)

TRANSLATIONS.

Dyspnœic Uræmia.—Dr. G. Variot (*La France Médicale*, 1881, p. 486) reports a marked case of this curious affection. A man of 21 was admitted to the hospital completely aphonic, and so dyspnœic that he was at first thought to be suffering with œdema of the glottis. His face was pale, the lips cyanosed, the respiratory movements frequent (twenty-five to thirty in the minute). The patient was torpid and apathetic, so that a history was difficult to obtain, but it was ascertained that he had had some throat-trouble for two or three weeks, and had lost his voice gradually during the preceding week. For two days he had suffered intense oppression. He had no cough, but occasionally spat a little blood.

Physical examination showed the patient of good figure and weight. The chest gave a sonorous percussion-note. Auscultation revealed sonorous râles over the upper portion of the lungs, with more confluent subcrepitant râles over the base of the left side. These signs, however, were not at all in proportion to the subasphyxiated condition of the patient. Auscultation also showed that the difficulty in respiration did not result from any laryngeal obstacle, for the vesicular murmur was perceptible from summit to base on both sides. The cardiac movement was tumultuous; there was no abnormal murmur; the pulse beat 130, and was small; temperature, 98.6° Fahr. Examination of the urine showed absence of albumen and sugar. Laryngoscopic examination showed

slight inflammation of the vocal cords, with some anæsthesia, accounting for the aphonia; the cause of the dyspnœa, however, remained obscure.

Uræmic dyspnœa was suspected, but the complete absence of albumen from the urine and of lowering of temperature pointed away from this diagnosis. The prognosis, however, was evidently grave. In fact, the patient sank rapidly; the respiration became more and more embarrassed. The evening after his admission the patient lost consciousness; the respirations became slower (seven to eight per minute), with long intervals. He died towards morning.

The autopsy showed both kidneys sclerosed, small, granular, and pale. The capsule was extremely adherent; there were no cysts. The cortical substance was reduced to a thickness of one and a half millimetres. The histological examination showed the well-known signs of interstitial nephritis; the tubules had, for the most part, disappeared in the cortical substance, and the sclerosed glomeruli were piled one above the other. The arteries were affected by endarteriïtis; some were calcified. The right heart was hypertrophied. The lungs were adherent with some little tubercular deposit, with a few caseous foci. All the bronchi were extremely congested and almost filled with reddish serous fluid of a frothy character. The vocal cords were congested, but did not explain the dyspnœa; they were not ulcerated. The urine examined after death gave a specific gravity of 1014°.

Secondary Syphilitic Laryngitis.—A recent number of the *Centralblatt für Chirurgie* (1881, p. 214) reviews a recent monograph by Gouguenheim, giving the following points of interest. Gouguenheim considers these affections very common. He has met with one hundred and nine cases in two hundred and seventy-five syphilitic individuals,—two-fifths of all cases. The trouble usually begins in the first six months of syphilis. Total and partial laryngeal affections are observed. General laryngitis is often found in connection with hyperplasiæ, which then attack the epiglottis in particular; more rarely the arytenoid region and the true vocal cords; most rarely the false vocal cords. Partial laryngitis shows the same frequency. Mucous patches, the occurrence of which within the larynx has been denied by authors, have frequently been observed, chiefly upon the epiglottis. Usually, in addition to the laryngeal syphilis, mucous patches are found in the mouth and throat, and on the vulva and anus; rarely skin-troubles alone. Patients in Gouguenheim's experience are young,—between eighteen and twenty-five. In advanced forms of syphilis a general hyperplasia is sometimes met with as an intermediate symptom between the secondary and tertiary laryngeal syphilis, which sometimes may assume very considerable dimensions. In earlier stages ulcerative erosions are frequently found, and these are seated on infiltrated surfaces or more rarely on circumscribed papules. Their usual locality is upon the epiglottis, especially upon its free border. On account of the elevation of the papule on which these erosions are situated, they often seem more deeply excavated than in reality they are. The true vocal cords are reddened, frequently cylindrically swollen, and maculated on the surface. Occasionally pin-head-sized whitish bodies are seen, which are supposed to be mucous patches. Now and then ulceration of the vocal cords is observed. Disturbance of phonation is very uncommon; and this is probably the reason why the affection is so frequently overlooked. Hoarseness only occurs when the true vocal cords are involved. Deglutition is rarely disturbed. Under appropriate treatment the affection lasts from two to eight weeks, rarely longer. Relapses are common, especially when the treatment is of too short continuance or under bad hygienic circumstances. The prognosis is favorable, provided decided hypertrophy has not taken place. The diagnosis is aided by the simultaneous occurrence of eruptions on the skin and mucous membrane. Treatment should be local and general. Gouguenheim gives bichloride of mercury to the amount of 1/6 to 3/4 grain, or the biniodide to the amount of 1/2 to 1 1/4 grains daily, or he orders inunctions. The latter are useful to the amount of a drachm or more, rubbed in twice daily. Locally, the nitrate of silver stick, or a ten per cent. solution, may be applied, or a four to five per cent. solution to the larynx.

Calculus in the Scrotum—Scrotal Lithotomy.—A. Lippomann (*Cbl. f. Chir.*, 1881, p. 256; from *Wratsch. Wedomosti*) gives the case of a man of 68, who, fifteen years previously, had suffered with gradu-

ally progressive stoppage of urine. His physician at that time performed an operation, removing a calculus weighing about four ounces. The wound made by the operation healed slowly and not completely, so that a fistula remained in front of the scrotum, at the root of the penis. The patient urinated through this instead of the urethra, and was obliged to use a small catheter to prevent excoriation. There was no incontinence. For some years the patient continued to feel well, but gradually urination through the fistula became more and more difficult, the scrotum became hard and increased in size, and he was finally obliged to seek the hospital.

On examination, Lippomann found the urethra impermeable to instruments, an obstacle being found in front of the symphysis pubis. The scrotum was enlarged to the size of an infant's head, and filled with a hard body. The testicles were pressed up against the inguinal rings, and could be made out only with difficulty, on account of their atrophic condition. Pus issued from the fistula, and a catheter introduced into it touched a calculus.

The patient was operated upon as follows. An incision having been made along the raphé down to the calculus, the latter was found to be made up of a number of pieces. Four separate portions were removed, weighing about ten drachms. The calculus was phosphatic, with mammillated surface, and of a grayish-yellow color; the various pieces showed facets at their point of juncture. The entire mass was about the size of a goose-egg. The operation, which was performed without anæsthetic, was well borne by the patient; the cavity was washed out with a two-per-cent. carbolic acid solution, the wound sewed up with carbolized silk, and a drainage-tube inserted. The patient made a rapid and good recovery. The fistula alone remaining unhealed served for voiding the urine, which was passed in a squatting position. The patient left the hospital in a greatly improved general condition.

Syphilis in Various Countries.—Rey (*Annales de Dermatologie et de Syphiligraphie*, 1880, p. 662) regards syphilis as at present an essentially universal disease. Two countries only in the known world are exempt,—Iceland and the interior of Africa. In Iceland the physicians say that though frequently introduced it never gains a foothold. That this is not due to climate is shown by the fact that syphilis is rife in such countries as Siberia and Greenland. According to Livingstone, the unmixed tribes of Central Africa do not have the disease, while it prevails among the mixed races. Those nations, says Rey, suffer most where syphilis is introduced for the first time, the cases being of a graver character. The symptomatology of the disease is everywhere the same, except that, of course, the color of the skin has some influence on the character of the skin-lesions. Climate is, on the whole, without essential influence. Authors are curiously at variance on this point,—some considering hot climates favorable to the course of the disease, while others take an opposite view. Facts are wanting. It seems certain, however, that hot climates are bad for Europeans who may have already contracted syphilis. In China the disease seems to run a peculiarly stubborn course. In Rey's opinion, this probably is the result of improper treatment. In high altitudes syphilis runs an unfavorable course. Warm climates appear to favor the rapid effect of treatment.

Echinococcus of the Mammary Gland.—E. Fischer (*Cbl. f. Chir.*, 1881, p. 272; from *Deutsche Zeitschrift f. Chir.*) adds another to the eighteen cases of this affection already on record. A woman 17 years of age observed a chestnut-sized growth in the right breast, which preserved the same size for three years, then beginning to grow and giving rise to pain shooting into the axilla, shoulder, and down the arm. When examined, a tumor the size of an apple was found in the breast, four or five centimetres from the nipple. Removed by an incision practised in the upper part of the breast, some fifty scolices were discovered.

After the operation, a tumor the size of a couple of hazel-nuts was found in the subcutaneous connective tissue just to the rear of the posterior axillary line, which it was found had appeared about the same time as the tumor in the breast, and had rapidly attained the size of a pigeon's egg, later becoming somewhat shrunken,—probably containing a dead echinococcus.

It is worthy of remark that the patient had experienced, some months before the development of the tumors, some pain and discomfort in the stomach, with vomiting. The termination of the wanderings

of the echinococcus probably coincided with the occurrence of these symptoms.

Suppurating Phlegmon of the Right Iliac Region—Thrombosis of the Vena Cava—Mortal Embolus of the Right Cardiac Cavity.—Rendu (*Cbl. f. Chir.*, 1881, p. 207; from a French source) gives the case of a patient who showed symptoms of an inflammatory affection of the right iliac fossa. It could not be ascertained whether this was due to an affection of the psoas or of the subperitoneal connective tissue. Disease of the vertebræ could be excluded. After incision and drainage of the phlegmon, improvement took place, which, however, after three days, was followed by marked febrile symptoms, vomiting, dyspnœa, violent cardiac action, and death. The autopsy showed the absence of peritonitis, and the presence of numerous recent and altered clots in the vena cava inferior, without anything else abnormal being found in the vessel itself or in its branches. Clots were found to have been carried from the vena cava to the right heart, so that the latter was quite filled with them. No emboli were found in the pulmonary arteries. How the vena cava became filled with clots could not be found out.

Complications of Erysipelas (*Giornale di Medicina Militare*, November, 1880; from *Gaz. Med. Ital.-Lombard.*, No. 39, October, 1880).—Dr. Carrier made the following observations during an epidemic which occurred in 1877 in the Hospital St. Eloi:

Quinsy often precedes the attack, and accompanies it throughout.

Manifestations of the erysipelatous inflammation are quite frequent in the pharynx and in the bronchial tubes, but rare in the larynx.

Pneumonia and affections of the pleura have been observed.

Pericarditis and endocarditis are not frequent,—of the two the former occurring the oftener. Myocarditis is very rare.

The writer, from these facts, draws the conclusion that erysipelas is an infectious, constitutional disease, whose action may extend to the internal organs. By preference it attacks the respiratory organs, but it may exert its influence over the central organ of circulation as well. w.

Permanent Dressings.—Dr. G. Neuber (*Cbl. f. Chir.*, 1881, p. 216; from *Archiv f. Klin. Chir.*), as the result of observations made under Esmarch at the surgical clinic of Kiel, gives the following aphorisms as a rule for the prevention of secreting wounds. 1. Close stitching of the wound; neither drainage nor openings in the skin in small superficial and smooth wounds. 2. Openings in the skin in large wounds of the soft parts, such as are situated for the most part immediately under the skin and are likely to heal by first intention within ten days. 3. Absorbable drains and simultaneous canalization in wounds which are not likely to be healed for some weeks, or which are situated deep down among the tissues or within some cavity. 4. Gum drains and simultaneous absorbable drains and canalization in wounds which from the beginning tend to heal aseptically but with suppuration.

Melœna in a New-Born Infant.—Dr. Diéterlin (*La France Méd.*, 1881, p. 513) delivered a healthy woman of an infant apparently in good condition, who passed normal meconium during the first twenty-four hours, but began to pass clotted blood at stool forty-eight hours after birth. The infant weighed three thousand two hundred and twenty grammes at birth, but lost two hundred and eighty-five grammes within four days, during most of which time he nursed well, but passed blood by stool constantly. On the fourth day death supervened. The organs were found anæmic, the intestine red and congested and filled with blood. There were no ulcers or erosions. There was no history of hæmophilia, and the cause of the hemorrhage remained obscure.

Polypus of the Ductus Choledochus—Icterus.—Pozzi (*Cbl. f. Chir.*, 1881, p. 224; from *Gaz Med. Ital.-Lombard.*) gives the case of a man of 40, whose liver was enlarged, and who showed icterus, with cerebral symptoms, dizziness, attacks of hallucination, and marked loss of flesh. After three months' sickness, the patient suddenly one day passed a large quantity of bile at stool, together with a polypus the size of a hazel-nut, the probable cause of the trouble, as no bile had passed at any previous time. The patient recovered rapidly.

Freeing Benzine from Offensive Odor.—According to Mr. Fairthorne, benzine may be freed from all offensive odor by shaking it up well with quicklime,—about three ounces to the gallon.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, JULY 2, 1881.

EDITORIAL.

WHAT WILL THE END BE?

IT would be interesting to know how many pages are added annually to the medical literature of the world. It is plain, however, that the *cacoethes scribendi* which affects so many medical men is a godsend to publishers and printers, enabling the former to revel in their palaces of stone and the latter to enjoy life in a more simple and yet perhaps no less happy manner. A few of those who furnish the "printer's devil" with medical copy get paid for their labor, but the great bulk of this in the aggregate gigantic mass of toil is either paid for not at all or with such a pittance as not to be worth naming. Nevertheless, the avalanche grows constantly. In this country alone the yearly output is by tons. Using the "Index Medicus" as a guide, we find that in the world last year eleven thousand seven hundred doctors thought they had something new to say, or some new way of saying something old. Mostly were they moved by vanity; and surely the outcome is vexation of spirit.

What the end of all this is to be is not easy to perceive. In fifty years more, if things go on, our unfortunate descendants may witness twenty thousand doctors, with vehement haste, yearly urging their pens in eager rivalry for fortune.

TREATMENT OF GOITRE BY CHLORIDE OF AMMONIUM.—Dr. Stevens has treated seven cases of goitre successfully by means of chloride of ammonium, in the dose of three grains thrice daily. Six young girls and a married woman of forty comprised the patients, and the duration of treatment was two or three months.

LEADING ARTICLES.

TENDON REFLEX.

THE curious phenomena classed under the name of "tendon reflex" have been known for a decade to physiologists and to those interested in the study of nervous diseases, but it is only within the last five or six years that their importance in the diagnosis of certain disorders has been appreciated and their general relationships with other nervous symptoms closely examined into.

An interesting review of the subject by Dr. Ollive, in the *Revue de Médecine*, considers the clinical history of the symptoms, the physiological explanation of them at present accepted, and their semeiotic value.

The so-called clonus or trembling of the foot, which is simply a sudden and rapid muscular contraction, is obtained by rapid flexure of the member, the leg being flexed or even moderately extended. The "knee phenomenon" is obtained when the patient is seated on the edge of the bed with his legs crossed and the one to be examined flexed over the other with the muscles in a state of relaxation. If then, with the edge of the hand or with a percussion-hammer, a smart tap is given to the rotular tendon just above its insertion into the tibia, the leg is observed to be suddenly raised and to fall again with each blow of the hammer, giving rise to a number of oscillations. Clonic contractions may also be produced in the knee as well as the foot by supporting the limb and percussing the ligament a number of times in succession or pressing firmly on the patella. Similar phenomena may be produced in various other tendons in different parts of the body. According to Strumpell, percussion of ligaments, of aponeuroses, and of bones likewise determines reflex contractile movements in the muscles,—an argument employed by those who deny that tendon reflex is of spinal origin.

The French theory of the origin of tendon reflex is that it is essentially spinal. The skin is not the point of departure of this reflex, for, on the one hand, it cannot be excited by irritation or blows upon the skin, and, on the other hand, if the skin is completely anæsthetized the tendon reflex can nevertheless be excited. Sachs

has shown that reflex movements can be aroused by excitation of the muscles or muscular branches of nerves. No terminal nerve-fibres are found, however, in the striated muscular fasciculi except motor fibres, the non-medullated nerve-fibres terminating in aponeuroses, with which alone muscular sensibility is connected. The excitation is produced at this point, the tendon only serving as an elastic medium for the transmission of vibrations which impinge upon the minute terminations of the aponeurosis. It is for this reason that the tendon should be in a condition of partial tension.

The investigations of Schultz and Furbringer, and also those of Tschiriew, have demonstrated that the "knee phenomenon" cannot be produced after section of the corresponding crural nerve, and that therefore the muscular succussion is not produced by direct mechanical excitation of the muscular fasciculi without the intermediation of the nerves. Not only does section of the crural nerve put an end to the "knee phenomenon," but section of the posterior roots of the sixth lumbar pair (in the rabbit), as also section of the cord between the fifth and sixth lumbar vertebræ, has the same effect. The reflex of the knee has its origin in a limited portion of the spinal cord,—namely, that from which the crural nerves take their origin. It may be perceived, therefore, that the muscles are in communication with the spinal cord by a nervous circle. This system is entirely distinct from the cutaneous nervous circle.

An important point in the study of tendon reflex is the measurement of the time required for the transmission of the impression; and this has been found by Brissaud to average fifty *millièmes* of a second.

Thus far we have considered the physiology of the "knee phenomenon" alone; but we must say a few words regarding the "foot phenomenon," which also merits attention. Considered for a long time as a reflex act produced under the influence of pathological irritability of the cord, since it does not exist in the normal condition, the "foot phenomenon" is explained by Charcot to consist in "violent alternative contractions of the flexors and extensors, and, under some circumstances, of the abductors and adductors." Why is not this epileptoid trepidation, like the "knee phenomenon," a normal incident? and why is it not produced except in those cases where the muscles are contracted? The tendinous nerves of the triceps cruralis, excited by percussion or by stretching the tendo Achillis, can, by reflex action, cause the muscles of the posterior portion of the leg to contract. The foot being extended, the tendons of the anterior portion of the leg are put on the stretch, and become, in their turn, the point of departure for the tendon reflex. Thus a true vicious circle is established, and artificial trepidation results,—clonus of the foot. This does not occur in the normal condition on account of the mode of insertion of the anterior muscles of the leg. The muscles are put upon the stretch before their tendon, and, in consequence, there does not occur any excitation of the centripetal nerves of the aponeurosis and of the tendon. In pathological conditions, however, exaggeration of muscular tension and contraction intervenes, and the terminal nerve-fibres are excited.

While the French hold the theory of the spinal origin of tendon reflex, the Germans (and Westphal among them) do not attribute tendon reflex to a reflex effect, but to a direct contraction produced by mechanical action on the tendon and muscle. Waller, a pupil of Ferrier, holds the same view. The curious fact, which at first seems to give irrefragable confirmation to the view of spinal origin (namely, that excitation of the tendon of one limb may give rise to reflex muscular contraction in the other), is disposed of by asserting that excessive contraction affects the trunk, giving rise to an apparent contraction of the other side.

The degree of intensity of the tendon reflex is the same as that of the muscular tonus,—a kind of insensible contraction, distinct from true flaccidity,—a condition of the muscle, in fact, where, as Claude Bernard has demonstrated, combustion goes on more vigorously than in the paralyzed muscle. If this muscular tonus is exaggerated, we have contraction, and in this state it is obvious that tendon reflex will be most marked. If the muscular tonus is, on the contrary, diminished, abolition of tendon reflex is observed, as in ataxy. The cord governs this tonus by the intermediation of the nerves of muscular sensibility, and the tonus itself is exaggerated not only in pathological conditions, but also by the action of strychnia.

Charcot has given to this condition the name of *spontaneous strychnism*. From this fact also is deduced the practical conclusion that it is unwise to give strychnia in hemiplegia where muscular contractility is preserved.

Türck and Bouchard have shown that paralysis following an apoplectic stroke becomes incurable only when an equally incurable lesion is developed in the spinal cord. This lesion has been shown to be situated in the antero-lateral column, particularly in the pyramidal fasciculus. The latter, as is known, is composed of all those nervous filaments which, leaving the motor convolutions of the cortex cerebri, are distributed to the various portions of the cord, and are in communication with the cells of the anterior horns. It is in a sort of great commissure established between the cerebral and medullary motor cells; and alterations which affect the motor cells of the convolutions or which suppress their communications with the pyramidal fasciculus are followed by degeneration of the latter, as if these cells played, as Huguenin supposes, the part of trophic centres. It is, in short, one of the principal excitants of the gray substance. Sclerosis of this fasciculus, therefore, must inevitably react on the cells of the anterior cornua, and exercise at that point, first, an irritative action, shown by exaggeration of the reflex and contracture. Later it may give rise to alteration of the cells, leading to paralysis, muscular atrophy, and disappearance of tendon reflex, the latter preceding and demonstrating the atrophy. The curious phenomenon of "arrest"—that is, where epileptoid spasms are controlled by movements similar to those causing the foot phenomenon above described—belongs under this head, but we cannot do more than mention it.

The foregoing remarks, necessarily somewhat extended, because the subject itself is somewhat obscure and not generally understood, except by special students of nervous diseases, may be summed up in the following definition of tendon reflex given by Charcot:

"*The tendon phenomena are the result of reflex action; they originate in the centripetal aponeurotic nerves situated between the muscle and the tendon,—nerves which pass with the posterior roots to the æsthesodic* nerves of the cord, which are themselves in connection with the motor cells of the anterior cornua; the reflex arc is completed by the motor cells and by the motor nerves which emanate therefrom. The arc of the tendon reflex is not the same as the arc of the musculo-cutaneous reflex.*"

Having thus set forth the character and physiological nature of the tendon-reflex phenomena, we shall at a future time indicate the semeiological value of the symptom, the importance of which in the diagnosis of certain nervous diseases cannot be exaggerated.

* Æsthesodic nerves are those having the faculty of conveying sensation.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting was held at the hall of the College of Physicians, Philadelphia, March 9, Dr. Albert H. Smith, President of the Society, in the chair. Dr. Little read a paper upon reflex affections of the eye. (See No. 354, p. 581.)

DISCUSSION UPON REFLEX EYE-DISORDERS.

Dr. S. D. Risley said that cases of eye disease due to conditions of general ill health frequently occur in the practice of the ophthalmic surgeon, but he believed it was rarely necessary to resort to the theory that they were reflex in their origin. In cases of hyperæsthesia of the retina, or of retino-choroidal irritation, it was his habit to exclude as a possible cause any existing refraction error by careful correction, and, if relief did not follow, refer the patient elsewhere for treatment of any existing trouble with other organs. He could cite a number of cases with eye-symptoms accompanying stomach-trouble, uterine disease, and other disorders, which did not do well until these other conditions were properly treated. They were not, however, regarded as sympathetic or reflex in origin. Given a case of hypermetropia, or other error of refraction, of low degree, and the patient may remain in ignorance of its presence until the general tone of the system is lowered by some depressing influence,—it may be by uterine disease, a miscarriage, or one of the exanthemata.

As long as the patient was well and strong, the eye-strain was endured without a murmur, but under the depressed tone of the system the eyes not only became painful, but the subject of pathological changes, if not relieved.

He thought hyperæsthesia of the retina very rarely present without definite pathological ocular change to account for it. He could recall but one case occurring in his experience,—a young woman with a family history of nervous derangements and mental

disturbance. She had been under the care of a prominent practitioner for loss of voice, for which he could discover no cause. She was sent to consult a gynæcologist, who pronounced the uterus healthy. A new direction, however, had been given to her thoughts. The voice was rapidly restored, and she became the victim of backache and various other symptoms of uterine disease, for which she was placed under the care of a female physician, who for several months treated the uterus locally.

Some of her associates about this time were under Dr. Risley's care for eye-trouble. In a few weeks she was brought, suffering from the most agonizing photophobia. The eyes were, externally, normal, $V = \frac{20}{XX}$ and eye-ground healthy, and were proved to be emmetropic under atropia. No improvement followed any treatment devised: so she was sent to the sea-side, with the remark in her presence that if there was not decided improvement in a week she was to return, and leeches would be applied to the temples.

She returned at the end of a week, entirely well.

When the general muscular vigor is below par from any cause, the muscles of accommodation and convergence do not escape the general weakness. This is frequently witnessed after wasting diseases. Nothing is more common than to hear the asthenopic patient date the beginning of his eye-trouble back to an attack of typhoid fever, or some other disease from which he had suffered. The weak eyes of ladies recently confined, he thought, were to be placed in the same category. Hypermetropic children not infrequently have strabismus for the first time during convalescence from measles or scarlet fever, and, as every one knows, this is the favorite time for an onset of phlyctenular disease. It would be unwise to treat these cases by local measures only. He believed, then, that, given a case of depressed health from uterine or other disease, the liability to eye-disease is greater than in health, and that this liability is greatly enhanced by the presence of some error of refraction, but that resort to a theory of reflex action is but rarely necessary.

Dr. Charles S. Turnbull remarked a difference between the eye-symptoms of pregnancy and those occurring in the condition discussed in the paper. His attention had been called to the latter when he was with Dr. Knapp. His experience was that the eye-symptoms in anæmic women are less frequent than in strong, robust women. So much was this the case that Dr. Knapp considered it to be a common defect in American girls, and occurring more frequently in the office practice among the better class of patients than among the poor. He (Dr. Turnbull) would not be willing to discuss them simply under the head of asthenopia, but as coming more directly under local anæmia or hyperæmia, and would then ascertain the condition of the uterus. The term ischæmia retinæ, or a sluggish condition of the retinal circulation, he preferred to either anæmia or congestion, as being more applicable. A cure is most often obtained where menstruation has been deficient or entirely suspended, owing to the symptoms being produced by rush of blood to the head (vicarious).

In cases of strabismus he would not blame the internal recti muscles alone, as stated by the preceding speaker, because myopia is not generally associated with it: he would rather in such cases blame the external recti, because hyperopia is the most common error of refraction accompanying such cases. In some cases hyperæsthesia of the retina is due to the lazy, inactive life so frequently pursued by young girls. He had never seen a case of undoubted hysterical asthenopia, but he had seen numerous simulated errors of refraction in cases where there was also functional disorder of the uterus.

Dr. John B. Roberts was interested from the fact that he had seen a number of cases in which the condition of the uterus had some connection with the eye disease. Eye-symptoms may in like manner be caused by defective teeth. He had seen patients suffering very great inconvenience from asthenopic symptoms without the slightest degree of error of refraction existing: hence the asthenopia was either muscular or retinal, and seemed connected with uterine disorder. He had also seen cases of evident eye-disorder in which, after the adjustment of spectacles, the expected relief was not obtained: it was then discovered that there was some uterine derangement. He did not believe that the influence was reflex, but it was connected with the general depression of health which might accompany any ailment. In one case, a healthy, robust woman, no asthenopic trouble was experienced until her first pregnancy: she got quite well, but the eye-symptoms returned with the next pregnancy. He had even seen corneal ulceration in connection with prolonged nursing of a child as a result of malnutrition.

These cases are very interesting, as they bear directly upon the question of treatment, which should be less special than general.

Dr. Little, in concluding the discussion, said that he had not claimed originality in his views, but merely reported a few cases to stimulate observation. In his second case he had tried electricity without lasting result. The eye-defects were thoroughly corrected, but even under the effects of atropia the blepharo-spasm continued, showing a reflex source of irritation outside of the eye; for if they had been in the eye the correction of the refraction and the instillation of atropia would have relieved the troubles. The third

case was handed over from the gynæcologist, and the eyes were treated afterwards. The first two cases were fully corrected before being passed over for uterine treatment.

The rule is in cases of eye-symptoms to correct any errors of refraction, and also to correct uterine trouble, kidney-trouble, or other source of disorder in the system. In cases of pregnancy the eye-disorder might be due to uræmia or Bright's disease; but these do not come within the scope of the paper.

March 23, 1881.

DISCUSSION UPON DIGITALIS.

Dr. H. C. Wood, in opening the discussion, referred to the current views in regard to the action of digitalis upon the nervous apparatus of the heart, and claimed for it a peculiar effect upon the heart-muscle. This influence, which had been fully demonstrated by physiological experiment and sustained by clinical observation, renders digitalis particularly serviceable in the condition of heart disease in which the increased work required of the heart is greater than the increase of the power, without regard to the particular valve which may be affected. It improves the nutrition of the heart by regulating its contractions and lengthening the diastolic interval, doing away with the rapid, imperfect contractions which interfere with the blood-supply of the cardiac muscle. In such cases the nutrition of the heart suffers because it is necessary to have lateral distention of the aorta in order to fill the arteries in the muscular tissue. A little digitalis steadies the heart, and therefore improves its condition and retards degeneration.

In chronic valve-trouble of the heart, digitalis is serviceable, and sometimes must be given in large doses. A half-drachm dose of the tincture apparently saved from impending death two cases of advanced heart-trouble coming under the speaker's observation: they afterwards got well enough to attend to their business. It enables the heart to gather up its strength, and keeps it going until the last. By the surgeon, digitalis is often used improperly. Thus, it is not rarely given in aneurism, where the great danger is from increased lateral pressure, not want of forward pressure. In one case coming under his observation digitalis caused the rupture of an internal aneurism at the hospital. The patient had been brought in without any diagnosis, and no one had suspected aneurism.

In acute diseases with failing heart, digitalis may be employed: such a condition may occur in asthenic or in the advanced stages of sthenic pneumonia. In the early stage of sthenic pneumonia it is improper to give it. Such a medicine as veratrum viride, which produces vaso-motor paralysis, is indicated, so "as to bleed a man into his own tumors." Blood is drawn to the lungs because there is there a local vaso-motor palsy: produce a general vaso-motor palsy, and the local attraction ceases. When the lung is consolidated throughout a large extent, the heart is overworked; by and by it begins to fail, the pulse gets rapid and feeble: now digitalis comes into play. It will save life in such a condition, when the patient without it must die. Take the case of a drinking man, seen a few days since, suffering with pneumonia, pulse 150 to 160, respirations 60 to the minute, delirium persisting for two or three weeks, expectoration of pure blood, &c. This man was given ten minims of tincture of digitalis every two hours, day and night, until the pulse fell to 60,—when the digitalis was stopped, and resumed as the pulse went up. By the aid of milk and whisky the patient was saved.

Two points in conclusion: (1) in regard to the cumulative action, (2) in regard to the cause of the slow action, of digitalis. The remedy acts slowly in producing its full effect, and its effects are very permanent when they do appear. Some agents act more quickly than others: digitalis acts slowly and cumulatively, not only because of its special influence upon the heart, but because it only comes very slowly in contact with the heart-structure, since it osmoses slowly into and out from the body. Where it fails to act upon the kidneys, it is more apt to act cumulatively upon the heart. The practical point is this: watch the kidneys when giving large doses of digitalis: if water is not passed freely, then cumulative action will be apt to occur. In a case of chronic pleurisy Dr. Wood tried to run off the water by the kidneys; the pulse ran down steadily from 70 to 40 in four days after the medicine had been withdrawn; it was a long time before the effect of the digitalis was manifested, and it was long before it ceased to act. In the pneumonia case, after the pulse began to drop, it was eighteen or twenty hours before it again reached the normal. The longer the digitalis is in acting, the more likely it is to have a lasting effect. After abdominal tapping, the digitalis often shows itself in reducing the heart's action. Either the digitalis has been lying in the intestines unabsorbed or in the cellular tissue: probably all the fluids are saturated with the drug.

Digitalis is a very useful remedy in cases of syncope and collapse. Formerly alcohol alone was used. One of the advances of modern therapeutics was to teach the danger of giving large doses of alcohol in cases of surgical shock. Belladonna and digitalis are proper remedies, given by the hypodermic injection. The pulse begins to fill up in twenty minutes or half an hour. No irritation is produced at the point of puncture. Throw in twenty minims of the tincture at once, and expect to find the result in half an hour.

He did not wish his remarks to be understood as declaring that digitalis was entirely without danger, but he had used it in hundreds of cases, and had seen men apparently dying revive under its effects. It is important to stop it as soon as evidence appears in the pulse that it is beginning to be absorbed. Used in this way, he did not believe that there would ever be any serious cases of poisoning with it.

Dr. E. T. Bruen could not agree with the speaker in condemning stimulants in shock: he had seen cases brought back to life by their aid when apparently dying of cardiac failure. Digitalis should be given in small doses in valvular disease, on account of the disturbance of digestion caused by large doses, and because he had seen brilliant results from small doses for months after he had utterly failed with large doses. As regards the danger, it can be guarded against by watching the pulse. He tells patients to stop the remedy when the pulse gets down to 60.

Dr. O'Hara endorsed the speaker's remarks in regard to the value of large doses. He prefers the infusion. He had observed that in some cases, however, the drug seemed to exert no influence at all.

Dr. J. T. Eskridge considered digitalis particularly serviceable in nervous heart and weak heart, and reported several cases. He also approved of its use in shock and collapse. He gives the infusion generally, but gives the tincture when he wishes to keep up the effect for a long time. He had never seen any cumulative action upon the heart.

Dr. Toboldt pointed out that there is a great difference in the infusion as obtained from different druggists. He had found that it is made by some simply by adding water to the fluid extract or tincture.

Dr. Benjamin Lee inquired as to the value of digitalin.

Dr. William B. Atkinson uses digitalis in full doses in scarlet fever, always having the infusion made under his own supervision from the leaves. He had seen cumulative action twice.

Dr. H. Leaman reported a case of a laboring-man with advanced heart-disease, with cartilaginous valves. As soon as he put him upon the digitalis he was able to go to his work, and he continued to perform manual labor without trouble or palpitation, from which he formerly suffered, although the medicine was not kept up.

Dr. W. R. D. Blackwood said that he had used it very largely in delirium tremens. He considered it important to watch the kidneys, especially where using large doses. In old topers he had given half-ounce doses of the tincture, and in one case he had used this dose for eight repetitions an hour apart. He believed that this patient had been kept alive for six years by digitalis.

Dr. L. Turnbull inquired in regard to the tonic effect of digitalis. Some authorities believe that it is not the weak heart that is acted upon, but the nervous apparatus: consequently the irritable and irregular heart would be more likely to be favorably influenced.

Dr. Wood, in closing the discussion, said that he would refer to but two or three practical points that had been touched upon. First, in regard to the choice of preparations: the general preference appears to be for the infusion. He believed that the only reason that the infusion was preferred as being more efficient is because it is usually given in relatively larger doses than the tincture. He would mention, in passing, that the infusion as well as the tincture obtained from an unknown druggist is not rarely an unreliable preparation. He had seen very few cases where the stomach-disturbance was considerable, and believed gastric disturbance was less apt to occur when the tincture was given than with the infusion. With regard to digitalin, he had not made much use of it: it is not the alkaloid, but merely a purified extract, and comprises at least two principles,—the one soluble in water, the other insoluble. It is uncertain in its composition and in its results. As the dose of digitalis is so small, it is not necessary to resort to this substance, with which you might get results or you might not.

He wished to be distinctly understood as discountenancing the use of large doses of digitalis until the small ones have failed: he would never use powerful remedies when milder ones will do. With regard to Dr. Leaman's case, the heart had apparently been starved, and the use of digitalis had flushed it with fresh blood and gave it a new stock of nutrition. In such a case he would advise continuing the remedy, giving small doses from time to time, in order to continue the effect. The action of digitalis upon the frog's heart is that it is rarely arrested in diastole, more frequently in systole. As regards the question of its effect upon the pneumogastric nerve, in some cases the effect is to destroy life in this manner. In such cases we can restore the action of the heart by cutting the pneumogastric nerve. As a rule, however, the effect is greater upon the heart than it is upon the nerve, and the animal dies of cardiac spasm. It has the same effect upon the pulse of mammals; its full effect produces a weak pulse, sometimes dicrotic: this he had seen beautifully illustrated in man. It means that there are two antagonistic effects upon the heart,—upon the heart-muscle and upon the brake-action: this is undoubtedly the explanation of the dicrotic pulse and of the double wave written upon the manometer. Later the arterial pressure is found to be falling; looking at the heart, the dilatation becomes less, the diastole becomes imperfect, only a small amount of blood now enters its

cavities, on account of the cramp of the muscular tissue, just as in the tetanic spasm or the muscles of strychnia-poisoning; then comes cramp of the muscles of respiration, and death. The pulse becomes frequent in digitalis-poisoning, because the heart is so constricted that the blood is dammed back and cannot get into the aorta.

A vote of thanks was, on motion, tendered Dr. Wood for his able remarks.

April 13, 1881.

SPECIMEN OF FALSE MEMBRANE FROM THE INTESTINAL CANAL. Presented by Dr. W. R. D. Blackwood, for Dr. B. Lee.

The patient is a married woman, about 45 years old, of nervous temperament, spare habit, rather anæmic, with a frequent and feeble pulse. Has partial anchylosis of the left hip-joint, and has suffered a rupture of one of the peroneal tendons of the same leg, from which she has been compelled for a year past to walk with a cane. Has suffered more or less from malaria at the West. Appetite and digestion good. About the middle of January last she had an obstinate attack of inflammatory diarrhœa, for which I treated her with minute doses of Dover's powder and calomel, followed by small doses of castor oil frequently repeated. It subsequently appeared that this attack was due to sewer-gas in her bedroom, which accounted for its persistence. One week since, she began to be sensible of a disagreeable feeling of abdominal distention, accompanied by soreness in the abdomen on motion, but not on pressure. This gradually increased for three days, and at the same time a general sense of nervous uneasiness, compelling her to keep in motion, developed itself. Finally, after an attack of severe "tearing" pain in the situation of the transverse and descending colon, she had an evacuation consisting principally of shreds of membrane like those which I present. These evacuations have continued at the rate of two or three a day, sometimes with and sometimes unaccompanied by fecal matter. There is no diarrhœa, and little if any febrile movement. No headache or nausea. The intense pain before the evacuation is relieved by the discharge of the offending material. This attack is not the first of its kind. She has had similar ones occasionally for three or four years, the general symptoms being such as characterize the present. The membrane has usually been discharged in strips about six inches long and half an inch or more in width, but the first which she ever passed was tubular and of considerable diameter. They appear to me to be extremely tough and coherent, and to be composed of distinct layers, so much so as to suggest a suspicion of their origin. They have been macerated in water and subjected to several washings since yesterday (Tuesday) morning, when they were extruded, which has of course diminished their tenacity. I would suggest the propriety of their being subjected to microscopic examination.

The specimens were referred for examination to the Committee on Microscopy.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, MARCH 10, 1881.

The PRESIDENT, DR. S. W. GROSS, in the chair.

Hypertrophy of nymphæ. Exhibited by Dr. B. F. BAER. (Permission having been on motion accorded him, Dr. Baer's paper will appear in the *Obstetrical Journal.*)

DR. FORMAD said that he had made a microscopical examination of a section of the specimen presented by Dr. Baer. The surface was covered by the normal cuticle of a mucous membrane somewhat hypertrophied, owing to exposure to the air. The rest of the growth consisted of succulent fibrous tissue, so that he would call it a polypoid fibroma.

Dr. S. W. GROSS asked whether Dr. Formad had noticed anything peculiar about the lymph-spaces.

Dr. FORMAD replied that in the single section examined by him nothing unusual was noted with regard to these cavities.

Case of alveolar sarcoma of the femur. Exhibited by Dr. C. B. NANCREDE.

The specimen was removed by exarticulation at the hip-joint, in January, 1881, from a man aged 35 years. The duration of the case is doubtful, but it probably extends over a space of about two years. A little over three months back, spontaneous fracture occurred. The tumor involves the lower half of the femur, the popliteal space, and apparently the tibia. Owing to the unfortunate decomposition of the specimen, nothing definite can be said about the deeper portions of the growth or the condition of the knee-joint. A loud aneurismal bruit was heard over all portions of the growth, which was of variable density. In the fresh state, upon dissection, the growth was strictly limited in front and laterally by the fibrous expansions of the quadriceps, but the posterior muscles were involved near their attachments. Section of some of the nodules revealed a growth which closely resembled normal brain-substance in consistence, etc. Microscopic sections were obtained from portions removed within twenty-four hours of the amputation, but, as before said, the actual involvement of the tibia or knee-joint could not be determined, owing to decomposition having taken place. The patient did well for a few days, but died finally on the eleventh day after operation. He wor-

ried and fretted so lest something *might* go wrong, that although the wound was well united, except at portions of its edges, a few drainage-openings, and its deepest parts, he actually seemed to die on account of his dread of death, which reduced his vitality to such a low ebb as to render him a ready victim to blood-poisoning, to which, although shown in no definite form, he seemed finally to succumb.

Osteo-sarcoma of knee-joint. Exhibited by Dr. H. F. FORMAD, for Dr. C. A. MCCALL.

Mrs. R., 30 years of age, has four children, had two miscarriages, and one set of twins at full time. Weighed while in health about one hundred and fifty pounds. Never had had a day's sickness previous to this lesion; not a trace of any hereditary or specific disease in her family.

Mrs. R. during the Centennial year experienced, for the first, pain upon protracted exercise, in the right knee. A few months thereafter the leg would become suddenly flexed without apparent cause, thereby occasioning frequent falls, one of which, while stepping out of a carriage, resulted in a violent blow upon the right knee against the edge of the curb-stone. Synovial inflammation at once set in, with all the usual symptoms,—pain, swelling, enlargement, fluctuation, etc. This condition becoming chronic, anchylosis to a considerable degree was established. In the latter part of 1877, Prof. Agnew broke up the adhesions and the leg was placed in Stromeyer's apparatus; this was borne but indifferently well, and before another six months the distortion was reproduced. At this time the swelling of the joint began to be more marked; pain was excruciating and intermittent; the patient's health began to give way; she became thin and anæmic, and, though not strictly confined to her bed, showed all the symptoms of general "break-up." The case then left my hands, but came again under my care one year ago, when I found the leg in much the same condition as now presented in the specimen. Her general condition of health was bad, and in addition she was pregnant. A delay of nearly a year for any surgical interference was thus forced upon me.

November 27, after the puerperal state had fully passed, and the patient being in good condition of nutrition, amputation was resorted to, and performed at the upper third of the thigh. She stood the operation well. The stump healed, and she is regaining apparent health.

At the time of the operation the tumor had reached the size of an adult's head. The skin was freely movable over the tumor, and no discoloration or ulceration was present. The lymphatic glands were not involved. The tumor was of white color, soft in consistence, contained numerous fragments of bone in its parenchyma, but was not enveloped in a bony capsule. The lower portion of the femur and parts of the tibia and fibula, as well as the patella, were involved in the new growth.

Microscopic examination revealed the typical structure of *alveolar sarcoma*, strongly intermingled, however, with the spindle-celled variety of sarcoma.

Dr. FORMAD said that, in addition to the information given in the notes, he would say that the patient had done well since the operation, having gained in flesh and strength. He thought that both Dr. Nancrede's case and his own were remarkable in this combination of round and spindle cells, which is certainly uncommon in such a situation, constituting the rare form of alveolar sarcoma.

Dr. GROSS called attention to the rarity of alveolar sarcoma, and said that these two specimens were, he believed, the only ones that had ever been exhibited to this Society. In his lectures before the College of Physicians upon sarcoma of the long bones, he had then only one case of alveolar sarcoma to report, the specimen having been sent him by Dr. Burchard, of New York. He thought that, contrary to Dr. Formad's opinion, the outlook for Dr. McCall's case was very bad, as this form of sarcoma is peculiarly fatal. He would also call attention to the unusual fact that the knee-joint had been invaded and completely destroyed. This was the first instance out of many examined by him where this condition had obtained. Extension of this disease from the tibia to the femur, or *vice versa*, is not uncommon, the morbid growth seeming to travel along the crucial ligaments. There seemed to be numerous portions of the specimen presented by Dr. Formad which were calcified. Dr. Gross would therefore class this tumor as a calcifying alveolar sarcoma.

Vesical calculus. Presented by Dr. C. B. NANCREDE.

C. S., aged 5 years, had been suffering from difficult and painful micturition for about three years at the time when I was asked to see him. Two years previously he had been taken to a hospital in this city, where the hypertrophied condition of his prepuce, instead of exciting suspicion of a vesical calculus, only induced the surgeon on duty to circumcise him. In the latter part of January, 1881, he was admitted to St. Christopher's Hospital under the charge of my friend Dr. Wm. H. Bennett, who, immediately suspecting the nature of his ailment, sounded him and readily detected a stone.

He kindly requested me to operate for him, which I accordingly did on February 9, 1881. No difficulty was experienced in reaching the stone, but it was only after prolonged efforts, consequent upon repeated failures, that, after enlarging the wound in the bladder, I finally extracted this unusually large stone

for so young a child. It measures one inch and a half, less a sixteenth, in the longest diameter, by one inch in width, by five-eighths of an inch in thickness, and weighed two hundred grains.

Vocal apparatus of the alligator.

Dr. C. SEILER said that during his recent stay in Florida he had occasion to examine the vocal apparatus of the alligator. To his surprise, in almost every instance there was more or less ulceration of the epiglottis, etc., in some cases amounting even to the total destruction of this structure. He had discovered that these lesions were due to a small variety of leech abounding in the Florida rivers. In some instances he had detected these creatures *in situ*, and the surfaces left upon their detachment were so exactly similar to those seen in the other supposed specimens of ulceration, that he was compelled to conclude that all were due to the same cause, viz., leech-bites.

THURSDAY EVENING, MARCH 24, 1881.

The PRESIDENT, DR. S. W. GROSS, in the chair.

Specimen of necrosis of radius. Exhibited by Dr. C. B. NANCREDE.

This specimen was removed from a married woman, 35 years of age, who three or four years since had her arm, as she calls it, "badly sprained." Some months after this the swelling and pain increased, suppuration ensued, and numerous sinuses formed. At the time of my examination, before admitting her to my wards in the Protestant Episcopal Hospital, the arm presented the ordinary appearance of necrosis with either fracture of the sequestrum or involucrum, as movement induced crepitus. At the operation it was seen that death of the whole shaft, for an inch or more, had occurred, that the necrosed segment had been nearly absorbed, and that its fracture had been the result of some trivial violence. The special point of interest was that nothing worthy of the name of involucrum had been formed, only a few nodules of osseous material being detectable in the surrounding periosteum. Condensing osteitis was present to a marked degree contiguous to the necrosed and carious bone, rendering its section very difficult. Dr. Nancrede thought that the specimen was of interest from the rarity of the failure of the periosteum, *in chronic cases* of bone-trouble, to form a marked involucrum.

IODOFORM IN GONORRHŒAL ORCHITIS.—Sabadini, in a case where there was enormous swelling and intense pain, applied an ointment of one part of iodoform to four parts of vaseline. The swelling disappeared within a few days, the patient going about as usual all the time.—*Gazette des Hôpitaux; New York Medical Record.*

PHILADELPHIA ACADEMY OF SURGERY.

STATED MEETING OF MARCH 7, 1881.

DR. S. D. GROSS, President, in the Chair.

DISLOCATIONS AT THE WRIST-JOINT.

DR. J. EWING MEARS reported two cases of posterior dislocations at the wrist-joint, occurring in boys aged respectively 17 and 12 years.

Case I.—J. M., colored, æt. 17, came to my office on the night of January 22, 1878, suffering from an injury of the right wrist. At the time of the receipt of the injury he was engaged in turning out the gas-lights in a gymnasium hall, standing for that purpose on a small step-ladder. Losing his balance, he fell from this to the floor, striking on his right side, his right arm being under his body, the wrist-joint bent, and the hand twisted inward. Regaining his feet, he found that he had sustained an injury to the joint. Slight pain was felt in the parts.

On examination, it was found that the movements of the joint were greatly impaired. The hand was slightly flexed, as were also the fingers. On the posterior surface of the forearm, just above the radio-carpal articulation, there was a marked projection, the surfaces of which were rounded and smooth. Anteriorly, there was a corresponding projection, formed by the lower extremities of the radius and ulna, the outlines of which could be distinguished by firm pressure. In the efforts which were made to elicit crepitus, it was found that the projecting surfaces could be separated to a slight extent, and that the continuity of the bones of the forearm could be distinctly traced.

Reduction was easily accomplished by extension and manipulation, and the functions of the joint immediately restored. There was no tendency to a return of the displacement, and careful examination failed to detect crepitus. A bandage was applied and retained in position for three days, for the purpose of affording support to the joint. Since the receipt of the injury the joint has been examined from time to time, and there has been found no evidence of the slightest impairment in its functions. The patient being present this evening, an opportunity is afforded of making an examination three years after the accident.

Case II.—In July, 1878, a boy, æt. 12 years, was brought to St. Mary's Hospital, who had sustained an injury to the right wrist-joint by a fall from a tree. He was greatly alarmed by the accident, and could give no intelligible account of how he alighted upon the ground. He made no complaint of pain on manipulation of the parts, and careful examination could not discover any marks or bruises upon the surfaces of the hand to indicate that he had fallen upon this part. The signs of posterior dislocation were as strongly marked as

in the previous case, and, before efforts at reduction were made, these were all verified by examination. Reduction was effected, and a roller applied as before. In a few days this was removed, and the movements of the joint were found to be unimpaired.

Dr. Packard said that he had met with three cases which he believed to have been luxations of the wrist.

Case I.—A. R. H., æt. 37, was admitted into the Episcopal Hospital, December 4, 1879, having fallen from a scaffold about twelve feet high. He was thought to have a Colles' fracture of the wrist; but there was no crepitus, the reduction was readily accomplished, and one week afterward the functions of the hand were perfect.

Case II.—G. B., æt. 17, came to the Dispensary of the Episcopal Hospital, December 15, 1880, with luxation inward and forward of the right wrist, from a machinery accident, the hand having been twisted on the forearm by entanglement in a power-band. Reduction was readily accomplished, and, as in the previous case, the recovery was very rapid. On account of a severe laceration of one finger, the hand was kept on a splint for some weeks, but on careful examination of the wrist two weeks after the injury, none of the well-known symptoms of the so-called "Colles' fracture" could be detected.

Case III.—This case is open to some doubt. D. K., æt. 15, was playing with other boys, when he fell off a railed door-step, and "twisted his wrist all out of shape." One of his comrades grasped his hand, and "pulled it straight." He came into my office immediately, and I found only some tenderness about the joint: this subsided in a very few days, and left no soreness or lameness behind it.

JOHN B. ROBERTS,
Recorder.

REVIEWS AND BOOK NOTICES.

TRANSACTIONS OF THE AMERICAN DERMATOLOGICAL ASSOCIATION, with the President's Address, at the Fourth Annual Meeting, Newport, R.I., August 31 and September 1 and 2, 1880. Official Report of the Proceedings, by the Secretary, DR. ARTHUR VAN HARLINGEN. Philadelphia, 1881. Pamphlet, 8vo, pp. 85.

The specialty of dermatology is one which lies closer to the work of the general practitioner than that of other specialists. Ophthalmology, otology, etc., require in every case peculiar manual dexterity in one who would practise in these branches with success. But the dermatologist is simply a physician whose studies lie in certain directions, not a skilful operator or manipulator. Moreover, he is daily digging his own grave. Of few devotees of medical science can the old Virgilian lines be so appropriately quoted,—

"Sic vos non vobis mellificatis apes."

Out of the slough of confusion and ignorance in which diseases of the skin seemed buried a few years ago, there has already risen a fair fabric, built by skilful architects, and as appropriate for its purpose as in the present state of our knowledge any work of the medical builder may be. The student, supplied with the text-books of to-day, may begin the study of dermatology with confidence, knowing that he shall not be overwhelmed with the jargon of an obsolete and confused classification and driven to distraction by the multitudinous synonyms of a barbarous nomenclature.

Much of this work of simplification and elucidation has been done by the dermatologists of America, and in no country has the study of skin diseases been carried on with such enthusiasm and vigor as in our own during the past decade. The address of the president of the American Dermatological Association, Dr. Duhring, contained in this volume of the Transactions, bears abundant witness to the labors of himself and his associates, since it is occupied with a short *résumé* of the dermatological work of the past ten years. Not least among the writings there mentioned are those of the eminent president himself, whose Treatise, the second edition of which we recently had occasion to notice, has done more to simplify and make clear the subject of which it treats than any other work published in the English language, and whose Atlas, now approaching completion after years of preparation, is one of the most creditable works which the profession of this country has as yet produced.

Of the various other papers which are abstracted in the volume before us, we may mention that of Dr. Greenough, on herpes progenitalis, that on the treatment of eczema of the hands and face, by Dr. Bulkley, and that of Dr. Heitzmann, on some experiments in epilation, as of particular interest to the general medical reader. The discussions on these topics, having brought out expressions of opinion from the best-known dermatologists of the country, add much to the interest of the papers themselves. Other papers are those on Medicinal Eruptions, by Dr. Van Harlingen; on Ainhum, by Dr. Da Silva, Lima; on Tumors of the Skin, by Dr. Heitzmann; on Papilloma Cutis, by Dr. Hardaway; a Report of a Case of Scleroderma, by Dr. Graham; Pityriasis Maculata et Circinata, by Dr. Duhring; The Kerion Stage of Tinea Tonsurans, by Dr. Atkinson; Lichen Planus of the Penis, by Dr. Bulkley; Report of Two Cases of Fragilitas Crinium, by Dr. Walter G. Smith. The report of the Statistical Committee is an analysis of 11,047 cases of skin

disease which had come under the care of the members of the Association during the year previous. It contains much interesting material. Appended to this is the annual report on leprosy in the United States, in continuation of the reports of former years. We understand that these have been made use of by the Superintendent of the Census in preparing a report upon the prevalence of this malady.

We may add, for the benefit of those who desire to consult the papers of which abstracts are given in these Transactions, that they will be found in full in the *Archives of Dermatology* for October, 1880, and January and April, 1881.

COULSON ON THE DISEASES OF THE BLADDER AND PROSTATE GLAND. Sixth Edition. Revised by WALTER J. COULSON, F.R.C.S. 4to, pp. xxxii., 607. London, J. & A. Churchill, 1881.

Not many books reach a sixth edition, and when they do it is a fair evidence of a lusty youth and a vigorous age. The twenty-three years since the last edition have seen so many discoveries and improvements in medicine that it is no surprise for the editor to tell us that nearly all the chapters have been rewritten and several entirely new ones have been added. Among the last, in graceful contrast to the chary treatment accorded it by Sir Henry Thompson, is one on litholapaxy; and Dr. Bigelow is rightly credited with not merely an improvement on an old method, but a new method. Indeed, one feature of the book is the thoroughness of the editor's knowledge of American surgical literature. Scarcely a chapter is read which does not mention our familiar names. To our surprise, therefore, we found one so well known as McClellan misspelled by the omission of the "c." There are, however, far too few illustrations. Few books bear illustration so well as surgical text-books; those especially of narrow scope should be full, giving the various instruments to be used, the procedures, the regional anatomy involved, etc. Among its readers will be many a one who does not know even the simpler but it may be less-used instruments, and he goes to just such a text-book as this for information and fails of his purpose. So exhaustive a treatise as this pretends to be, with its thirty-two chapters and over six hundred pages, ought to have vastly more than twenty-two engravings.

The subject of calculus is very fully and excellently treated, and we commend especially the chapter on the Solvent Treatment of Calculus. *Per contra*, there is no chapter on the analysis of the urine, nor are even the scattered directions on the subject of great value.

To give, however, an idea of its contents, or even a brief discussion of scattered points, is impossible in our limited space. We can only, therefore, commend it as an excellent hand-book on its subject, thorough, modest, and as complete as any we know.

W. W. K.

GLEANINGS FROM EXCHANGES.

THE TREATMENT OF ANÆMIA.—Dr. Sidney Coupland, at the conclusion of his Gulstonian Lectures on Anæmia (*British Medical Journal*, vol. i. p. 633), speaks of hygienic measures including hydrotherapy, and endorses the conclusions of Drs. Mary Jacobi and White as to the increased tissue-change brought about by the use of the wet pack with massage in addition to ferruginous medication. As to diet, Dr. Coupland recommends meat in considerable quantity as soon as the digestive organs are capable of disposing of it; but when, as so often happens, the digestive power is at a minimum, then recourse may be had to meat essences, peptonized foods, and (as an extreme measure) nutrient enemata. The anæmia is sometimes partly caused by a non-nitrogenous diet, and patients are averse to it, but it is essential.

Of medicines, iron of course stands first. The action of iron has never been explained, nor why the best results in the most marked cases of chlorosis are obtained by the administration of heroic doses far in excess of what is actually required in blood-formation, and much more also than is actually absorbed. Dr. Coupland gives a table of cases of anæmia treated by iron and arsenic showing the increase in value of the corpuscles and also their increase in number. He prefers the sulphate in large doses, and says its rapid effect in chlorotic anæmia is surprising. It is usually well borne.

Next to iron, and in some forms of anæmia to be preferred to it, is arsenic. It is almost the only drug which has been successful in the treatment of severe idiopathic anæmia, which more often resists all medication. In one case cited, where the estimated number of blood-corpuscles per cubic millimetre was 560,000, or 11.2 per cent., four minims of Fowler's solution with digitalis were given six times daily. In two months' time the number of corpuscles had increased to 64 per cent. In this case iron had failed. Quinia, strychnia, and the mineral acids as usually employed are valuable adjuvants.

Transfusion in symptomatic anæmia, as from loss of blood, Dr. Coupland thinks is advantageous. It is another matter, however, in regard to transfusion in pernicious anæmia. Of twenty cases reported there were only six recoveries, all occurring in the practice of Quinke, the originator of the plan. Dr. Coupland thinks Quinke's success is due to the fact that he has resorted to the method earlier in the course of the disease. Quinke

thinks that in transfusion the blood is reinforced with functionally active elements; and the results of his cases apparently bear out that opinion. Transfusion, then, is a correct and rational procedure, and one which we are bound to adopt in these cases of progressive idiopathic anæmia, if no ordinary treatment makes any impression on them.

Vicarious Menstruation from a Sebaceous Tumor of the Auditory Meatus.—Dr. J. Orne Green (*American Journal of Otology*, 1881, p. 133) gives the case of a young lady who came under his notice in 1877, suffering from occasional bleeding from the right ear.

There was no pain, deafness, or noises; and examination showed both ears absolutely normal in every respect, with the exception of a very slight prominence just at the edge of the right meatus, probably due to a former furuncle. The bleeding was at first supposed to be nothing more than an excessive flow of discolored semi-fluid cerumen, and the patient was dismissed. She appeared again two years and a half subsequently, stating that the bleeding had rather increased in quantity, and Dr. Green was then informed that it occurred at the menstrual periods. At such times the patient often, but not always, suffered from severe headaches; and if the bleeding from the ear occurred during such headaches, it would relieve the head. The patient had formerly suffered from bleeding at the nose during the menstrual periods, but this had ceased since the ear-trouble had begun. The hemorrhage was quite profuse,—sufficient at a time to cover a handkerchief,—and might occur several times during one menstruation. There were no symptoms in the ear,—neither pain, noises, throbbing, nor deafness; and examination showed nothing abnormal except that at the seat of the former slight prominence there was now a distinct sebaceous tumor as large as a bean upon the lower edge of the meatus, which the patient said had been increasing in size for some months. The skin over this was extremely thin and adherent to the tumor, and its surface was dotted with minute red spots, the seat of the last hemorrhage a few days before. As the tumor appeared to be without doubt the source of the hemorrhage, it was removed by elliptical incisions embracing the base and then dissecting out the whole mass. The contents of the cyst was sebaceous secretion, and the growth was nourished by a single artery, of large size considering the size of the tumor, which entered at its base. Five months afterwards there had never been any return of the hemorrhage from either ear or nose, and the headaches at the menstrual period were about the same as ever,—certainly no worse.

Dr. Green mentions a similar case which came under his observation, where, during menstruation, there was hemorrhage from the mucous surface of the tympanic cavity, the drum-head having been destroyed by previous disease.

Paralytic Chorea.—Dr. Gowers (*British Medical Journal*, vol. i., 1881, p. 636) says that in a well-marked case of common chorea three symptoms may commonly be noted,—spontaneous movement, incoördination of voluntary movement, and muscular weakness. Any one may predominate, and Dr. Gowers gives several cases where muscular weakness predominated the other elements; muscular spasm and incoördination were so slight as to be apparently absent. After giving notes of the cases (five in number), Dr. Gowers goes on to say that the age at which this form of chorea occurs is from seven to fifteen. Gradual loss of the use of one arm commonly first attracts attention, or, in some cases, the sudden dropping of objects, so characteristic of the imperfect muscular control of chorea, is noted early. In rare cases slight clonic spasm occurs in the affected arm at first, and passes off subsequently. The loss of power may be very great and real, or it may be much less than the loss of use of the limb would suggest. In these cases there is rather inaction than paralysis. The affection is usually confined to one arm; there is no hemiplegic weakness, no paralysis of face, tongue, and leg. Both arms may be affected, but one is always weaker than the other. Close and continued observation will usually detect an occasional slight choreic twitch, even in the arm which is weak, but more often conspicuous in the other arm which is the less weak, or even strong. Sometimes slight clonic contractions may be noted in the legs. The affection may pass off without choreiform movements being more conspicuous. Frequently, however, these subsequently come on; and they may be even more marked as the power in the arm becomes greater.

Whenever a child of seven to fifteen suffers from gradual loss of power in the arm, and presents no weakness in face, tongue, or leg, the disease, so far as Dr. Gowers has seen, is always chorea. If the nature of the case be suspected, confirmatory evidence,—slight occasional spasm,—if looked for, will commonly be at some time detected, either in the weak arm or in the other. The course of these cases is often tedious, and, as the choreoid movements may increase as the weakness passes off, the patients often seem to the friends to be getting worse when really getting better. Dr. Gowers has never seen this form pass on into severe general chorea.

The cases given were treated by strychnia and arsenic.

Treatment of Some Forms of Epilepsy.—Dr. Ramskill, in a clinical lecture on this subject (*Lancet*, May 7, 1881), says he gives carbonate of ammonium with the bromide of potassium. It has long been known that the addition of this drug increases the effect of the bromide. It has also the advantage of

being an antacid and stimulant. It is of great use when the iodide and bromide are administered together, and, indeed, in every case where there is much depression. Bromide of lithium is supposed by some to be a more powerful salt than the bromide of potassium or that of sodium. Dr. Ramskill thinks well of giving the potassic salt for a period, and, when its action ceases to be protective, adding small doses of the lithium salt. In some cases of syphilitic epilepsy large doses of iodide of potassium are curative, but in a few others very large doses having succeeded to a certain point then suddenly fail. At this juncture more iodide of potassium will not succeed, but the addition of a few drops of tincture of iodine makes a combination which acts magically on specific disease.

As to the dose of the potassium salt, Dr. Ramskill finds that forty-five to sixty grains a day are enough for an adult. No more than just sufficient should be used. Voisin says that a therapeutic dose of bromide of potassium is not reached until reflex nausea is suppressed on introducing a spoon as far as the epiglottis: it is not until then that the bulb is certainly acted upon and its excitability diminished. Dr. Ramskill thinks that this statement is not universally true, and that the epileptic fits may be subdued without going so far as the suppression of reflex nausea, and *vice versâ*. Bromide has far more influence over the *grand mal* than over the *petit mal*. The more frequent and violent the fits, the more marked success is to be gained by treatment. Too much bromide should not be given, for, if bromism once ensues, the treatment must cease, and the patient suffers from the effect of the medicine, while the case relapses as to the occurrence of fits. The bowels should be kept open, and in young cases an ice-bag may sometimes be worn next the spine for two or three hours every day. A pill of valerianate of zinc, aloes, and conium is given at night in some cases; in others, camphor and chloral inunctions are used with success.

Syphilis and Tubercle of the Throat.—Mr. Lennox Browne (*British Medical Journal*, vol. i., 1881, p. 685) says the voice of syphilis is generally hoarse, but rarely aphonic, because there exists congestion or ulceration, with irregular thickening; whereas in phthisis complete loss of voice is a very early symptom, and is due partly to muscular enfeeblement and deficient lung-power, but mainly to mechanical impediment to approximation of the cords, caused by the swelling of the sub-mucous tissue covering the arytenoid cartilages. Respiration is rarely continuously affected in syphilis, except in the later stages, when there is stenosis of the glottis, though acute attacks of dyspnœa, due to œdema, are not uncommon. In either case, paroxysmal stridor is the form in which this symptom is most often present. In phthisis, breathlessness is a constant and early symptom. There is no pain in syphilis, even with considerable ulceration, except where there is perichondritis. In laryngeal phthisis there may be acute agony in the performance of every functional act. As to the physical or objective evidence in syphilis, the order of things is: congestion, ulceration, cicatricial narrowing, and deformity; in phthisis, anæmia, gray semi-solid thickening, and ulceration. Mr. Browne insists strongly on the characteristic appearance of the red, angry, pinched-out, deep, excavated ulcer of syphilis,—the epiglottis, for example, frequently looking as if a piece had been bitten out of it by some rodent animal, as a rat; whereas in phthisis the ulcers are pale and feeble, and begin as small, superficial, worm-eaten points, gradually commingling so as to resemble rather the nibbling of a mouse. Mr. Browne went on to urge that a decided diagnosis should be given in the early stages of laryngeal trouble, and that every means should be employed to make that diagnosis an exact one. He has often been able to confirm a doubtful diagnosis by means of the thermometer and weighing-scales, especially in cases of tubercle affecting the larynx, before the stethoscope revealed any signs of active disease in the lungs. The tuberculous character of the disease may often be recognized by means of the laryngoscope also, when stethoscopic examination gives purely negative results.

Belladonna-Poisoning treated with Pilocarpin.—Dr. Grattan (*British Medical Journal*, vol. i., 1881, p. 594) gives the case of a woman of 42, who drank by mistake two ounces and two drachms of belladonna liniment (B. P.). She discovered her mistake, and took two teaspoonfuls of mustard in water with no effect; walked a short distance, purchased an emetic, which she drank, returned home, and felt dizzy, her sight going and shadows before her eyes. She lost the power of speech, became greatly excited, had convulsions and vomited freely, and then lapsed into profound stupor. Seen by the doctor for the first time at 10.45 P.M., nearly six hours after the ingestion of the belladonna, the pupils were widely dilated, face swollen and bluish, pulse almost imperceptible, respiration twenty-five. A stomach-pump was introduced, and the stomach thoroughly washed out with mustard and water. Vomiting took place in half an hour, and sensibility began to return, but the patient soon relapsed into stupor, in spite of cold affusions, etc. At 3 A.M., ten hours after the ingestion of the belladonna, one-fifth of a grain of pilocarpin was injected subcutaneously, the dose being twice again repeated at intervals of fifteen minutes. After the third dose there was decided improvement; consciousness began to return, and the pulse became stronger. After the fourth dose the pupils began to contract

under the influence of light. From this time improvement was rapid. There was dizziness, with dilatation of the pupils, for two days. Half-drachm doses of tincture of opium were given every night until the third day, when she had entirely recovered. Four-fifths of a grain of pilocarpin in all were given. It appeared to act as a direct antidote to the belladonna. It did not cause the least perspiration.

Source of the Liquor Amnii.—Wiener (*Edinburgh Medical Journal*, May, 1881; from *Archiv f. Gynäkologie*) injected coloring-matter under the skin of fœtal rabbits, and found that it was secreted from the kidneys in one case within twenty-five minutes, and in another case within a few hours. This shows that the fœtal kidney-secretion is not so slow a process as some observers would have it. He then argues that the fœtus must void its bladder, as when examined it is as often found to contain urine as to be empty. The author discusses and controverts *seriatim* Ahlfield's arguments against the possibility of the liquor amnii being the product of fœtal kidney-secretion. He gives a case where a pregnant woman died through accident, and where the fœtal bladder was found distended. The fœtal kidney has the same structure as that of the adult; and for this reason, as also because bile is known to be secreted during intra-uterine life, Dr. Wiener argues that urine is then secreted also. In answer to Ahlfield's objection that in cases where the kidneys were entirely absent the liquor amnii was still present, the author says that it is possible that other fœtal structures may perform the functions of the missing organ, just as in the adult the sweat-glands occasionally act for the kidneys to some extent when these latter are diseased. In addition, cases are known where deficiencies in the kidneys were accompanied by diminished liquor amnii. Wiener concludes that there is no doubt the kidneys secrete urine during intra-uterine life, and that this is voided at intervals from the bladder. In the earlier months the secretion from the skin and the mother's blood contribute, but the fœtal kidneys are the main source.

Congenital Closure of the Posterior Nares.—At a recent meeting of the Obstetrical Society of Edinburgh (*Edinburgh Medical Journal*, May, 1881, p. 1035), Dr. Ronaldson gave the case of a female child born at full term, and apparently healthy, except for some peculiar obstruction to its breathing. On attempting to inspire, the lungs were not inflated, while the under lip and cheeks were sucked in. On slapping the buttocks to make the child cry, there was no difficulty to free respiration when the mouth was opened. On keeping the mouth open by a spoon and pulling the tongue a little forward, it breathed well and steadily and cried lustily. There was, therefore, no obstruction to the respiration through the mouth and larynx. On examination the nostrils were found filled with a glue-like translucent substance which could be pulled out *en masse* like a piece of tough glue. It was evidently a collection of inspissated mucus. After clearing the nose of this mucus an attempt was made to blow air through the nares, but failed. The passage of a probe was also attempted, but failed. The child died within twenty-four hours. Post-mortem examination showed that the posterior nares were completely occluded by a firm membrane. No other abnormality was found. The case, Dr. Ronaldson thinks, illustrates the fact that breathing through the nose is the natural method of performing that function, and that the infant has to learn to breathe through its mouth.

Foreign Substances introduced into the Brain with Impunity.—At a recent meeting of the St. Louis Medical Society (*St. Louis Medical and Surgical Journal*, May, 1881, p. 566) a curious case was described of an insane convict who was in the habit of inserting wires, nails, etc., into his brain through an opening made in the skull by means of an awl. One of the wires was so long that it penetrated the brain-substance completely and struck against the skull on the other side. After the discharge of this convict from prison, he procured some morphia for the purpose of overcoming sleeplessness, and, taking an overdose, died.

A post-mortem examination was made by Dr. Carpenter, assisted by Dr. Sayer, of Leavenworth. In the substance of the brain the following foreign bodies were found: first, a wire four and three-fourths inches in length; second, a wire three and seven-eighths inches long; third, a wire six and three-fourths inches in length; a wire was removed from the middle lobe two and one-sixth inches long; one in the anterior lobe two and three-eighths inches long; a nail removed from the anterior lobe two and one-quarter inches in length; a needle removed from the middle lobe one and five-eighths inches in length. These were encysted in a manner in the substance of the brain, and apparently gave him no trouble whatever.

The patient had shown no psychical peculiarities during life which could be attributed to the presence of foreign bodies in the brain.

Case of Remarkably Low Temperature.—Dr. Walter Mendelson (*New York Medical Record*, June 4, p. 627) gives the case of a man brought into the New York Hospital in a starving condition, extremely emaciated, weak, and almost voiceless. The surface was cool, the hands and feet being cold; the heart-sounds were almost inaudible, and the pulse beat forty-three in the minute; the temperature, taken several times and with two different thermometers, in the rectum, was 90.6° F. He was ordered stimulants by the stomach, with a hypodermic injection of equal parts of brandy and ether. Food was given

gradually, and the patient slowly recovered strength, the thermometer showing a progressive increase in temperature almost hourly until the normal was reached in about twenty hours. There was a tendency to fall, however, which persisted for some days, the thermometer showing 97.5° in the morning, but always rising to the normal in the afternoon. There was no febrile reaction, the highest temperature being 99.6° on the third day after admission. The digestion seemed in no way disturbed, for three days after admission the patient was eating heartily of everything, and was taking cod-liver oil and iron. He soon regained strength, but appeared to be in a state of mild dementia, which persisted during the two or three weeks of his stay in the hospital. His previous history in respect to mental condition could not be ascertained.

Ovariotomy and Parotitis.—It is an established fact that orchitis and inflammation of the parotid may mutually complicate each other. Moreover, there has been observed a relation between inflammation of the salivary gland in question and that of the external genital organs and the ovaries. Facts in support of this opinion are found in the works of Bouteiller, Meynet, Peter, and Billroth. Schroeder, who had never met parotitis as a complication of operations on the female genital organs, has just seen it as a sequel of five ovariotomies, two of which proved fatal (*Il Morgagni*). He comes to the conclusion that parotitis is a grave complication of gynæcological operations.—*Medical Press and Circular.*

Treatment of Frequently Recurring "Erysipelas" of the Face.—Dr. James Braithwaite (*British Medical Journal*, vol. i., 1881, p. 681) says that for many years his father and himself have used with entire success a strong solution of tannin (four to eight grains to the drachm of alcohol and water). This application, which is not disagreeable to the patient, should be painted over the parts affected with a soft brush every two or three hours, and allowed to dry, the patient being careful to keep the face from the fire. If there is a tendency to frequently recurring "erysipelas," it is well to keep the tannin at hand, as it will always arrest a threatened attack.

Unusual Form of Death in Typhoid Fever.—At a recent meeting of the Dublin Pathological Society (*Brit. Med. Jour.*, vol. i., 1881, p. 647) Dr. Hayden showed the small intestines of a patient dying suddenly in the fifth week of typhoid fever. There was congestion of the Peyerian patches and glandular enlargement, but no ulceration. The thoracic viscera were, unfortunately, not examined, but Dr. Hayden thought the death due to pulmonary embolism. The patient, with no unfavorable symptoms but high temperature, was suddenly heard breathing stertorously, and found struggling for breath, and shortly died.

Calamine Lotion.—The following is the formula prescribed by the late Dr. Tilbury Fox:

℞ Levigated calamine, gr. xl;
Oxide of zinc, gr. xx;
Glycerin, ♏xx;
Rose-water to ℥j.

The main point is to get the white calamine, and not the red. It is a very soothing application, and is a great favorite with ladies who have flushed faces. It should be applied with a small, soft sponge, and allowed to dry on, the excess of powder being lightly dusted off with an old pocket-handkerchief.

MISCELLANY.

Preserving-Fluid for Meat.—Wickersheimer has patented a new preservative fluid,—this time for keeping meat. Its composition is as follows: thirty-six grammes of potassa, fifteen grammes of chloride of sodium, and sixty grammes of alum are dissolved in three litres of water, the solution heated to 50° C. (122° F.), and afterwards nine grammes of salicylic acid added, together with forty-five grammes of methylic alcohol and two hundred and fifty grammes of glycerin. In smaller animals, one hundred grammes of the liquid are used for every kilogramme of weight of body; in larger animals, the amount may be reduced to forty grammes per kilogramme. The liquid is either injected before slaughtering, directly into the heart, or, after slaughtering, in the carotid. In the case of neat cattle and hogs, three grammes of saltpetre are added to the above liquid. The preserving power of the latter may be augmented by increasing the methylic alcohol to twenty grammes, salicylic acid to twelve grammes, and glycerin to four hundred and fifty grammes per litre of liquid. The meat may then be preserved two or three weeks entirely without odor.—*British Medical Journal*, vol. i., 1881, p. 680; from *Chem. Zeit.*

Medicine and Fiction.—The *British Medical Journal* calls attention to a recent French novel of which a hospital interne is the hero. M. Jules Claretie's work is entitled *Les Amours d'un Interne*. The hero is deeply attached to a young lady who has become a ward-maid in *La Salpêtrière* in order to wait upon her mother, obliged through poverty to become an inmate of that institution for the relief of hystero-epilepsy. The heroine, in love with another gentleman, unwittingly asks her lover the interne whether she may marry without danger of transmitting insanity, and thus the plot is evolved. Various scenes of a most exciting character are depicted, with the aid of Charcot's writings, etc.

A New Pair of Siamese Twins.—The *Wiener Med. Presse* contains an account of the brothers Tocci, born near Turin in 1877.

These creatures have two heads, two pairs of arms, and a double thorax with independent thoracic organs. From the sixth rib down, however, they have one body in common,—a single abdomen, a single umbilicus, one anus, one right leg, and one left leg. The genital organs comprise a penis and scrotum, but the rudiments of a second masculine genital organ can be discovered posteriorly, which occasionally permits a small portion of urine to escape. Viewed from behind, there are two separate vertebral columns, two sacrums, and three buttocks, of which the middle one is merely the result of union of the other two and contains a rudimentary anus. One anus serves both infants. The right leg is under the control of one twin, and the left, which is clubbed, of the other. Though well and strong, they cannot walk on this account. The personality of each infant is distinct; one cries or sleeps while the other may laugh or be awake. They are gay and lively with each other and with strangers. The heads usually lean one to the left, the other to the right, but one at a time may place the head in a perpendicular position, provided the other leans over a little more horizontally.

The *Réveil Médical*, from which we take this account, gives a picture.

A NEW TEST OF INTELLIGENCE.—The Parisian scientist Dr. Delaunay has made the curious discovery that to ascertain the qualities of a cook it is sufficient to give her a plate to clean, or sauce to make, and watch how she moves her hand in either act. If she move it from left to right, or in the direction of the hands of a watch, you may trust her; if the other way, she is certain to be stupid and incapable. Similarly, the intelligence of people may be gauged by asking them to make a circle on paper with a pencil, and noting in which direction the hand is moved. The good students in a mathematical class draw circles from left to right. The inferiority of the softer sex (as well as of male dunces) is shown by their drawing from right to left; asylum patients and children do the same. In a word, *centrifugal* movements are a characteristic of intelligence and higher development; *centripetal* are a mark of incomplete evolution. A person, as his faculties are developed, may come to draw circles the opposite way to what he did in youth. Dr. Delaunay has some further extraordinary conclusions as to the relative positions of races in the scale of development from the way they wind their watches and make their screws.—*Journal of Chemistry.*

THE PLAGUE.—This scourge has been ravaging the banks of the Lower Euphrates and the villages of Mesopotamia. Quarantine against it has been declared by the Egyptian authorities. In spite of this it is said already to have crossed the Mediterranean, and one or more deaths from it have been reported at Seville, Spain. The littoral cities of Southern Europe are by no means in such superior sanitary condition that all danger is averted of another experience such as Marseilles had in 1722.

THE NEW FRENCH SCIENTIFIC JOURNAL.—The Minister of Public Instruction has determined to publish a new scientific journal, under the title of *Revue des Sciences.* It is to be printed at the National Printing-Office, and sold as cheaply as possible. A number, containing about one hundred pages, will appear every month. Professor Milne-Edwards is to be the editor of the review, the object of which will be to give an analysis of all the scientific work done in France during the current year.

Qu. Quid est creare? (*What is creating?*)

Ans. E nihilo facere. (*To make out of nothing.*)

Rej. Bene; te doctorem nunc creavimus. (*Very well; we now create you a doctor.*)—*Exchange.*

PERFUMED CARBOLIC ACID is a solution of the acid in alcohol, with oil of lemon added. The proportion is: carbolic acid, 1; oil of lemon, 3; alcohol, 100.

NOTES AND QUERIES.

REMOVAL.

The personal address of Dr. H. C. Wood, Editor, will hereafter be 1925 Chestnut Street, instead of 1631 Arch Street.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM JUNE 12 TO JUNE 25, 1881.

HARTSUFF, A., MAJOR AND SURGEON.—To proceed to the Cantonment on the Uncompahgre, Col., and report for duty to Col. R. S. Mackenzie, Fourth Cavalry, commanding. S. O. 113, Department of the Missouri, June 8, 1881.

MIDDLETON, J. V. D., MAJOR AND SURGEON.—Having reported in person, is assigned to duty at Fort Hays, Kans., relieving Assistant-Surgeon Munn. S. O. 122, Department of the Missouri, June 21, 1881.

GARDNER, W. H., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for four months on surgeon's certificate of disability. S. O. 138, A. G. O., June 18, 1881.

MUNN, C. E., CAPTAIN AND ASSISTANT-SURGEON.—When relieved by Surgeon Middleton, to proceed to Fort Bayard, N.M., and report to the Commanding Officer for duty. S. O. 122, c. s., Department of the Missouri.

DE WITT, C., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for four months. S. O. 137, A. G. O., June 17, 1881.

TORNEY, G. H., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for one month, with permission to apply for an extension of one month, to take effect when relieved by Assistant-Surgeon A. W. Taylor. S. O. 122, Department of the Missouri, June 21, 1881.

TAYLOR, A. W., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—To proceed from Fort Supply, Ind. Ter., to Fort Lyon, Col., and report to the Commanding Officer for temporary duty. S. O. 122, c. s., Department of the Missouri.

PHILADELPHIA, JULY 16, 1881.

ORIGINAL COMMUNICATIONS.

GONORRHŒAL PROSTATITIS.

BY CHARLES L. MITCHELL, Ph. D., M.D.,
Professor of Chemistry, Sanitary Science, and Venereal Diseases in the Medico-Chirurgical College of Philadelphia.

OF all the complications attending the course of an attack of true specific urethritis, there is none to be more dreaded by the practitioner than the extension of the inflammation to the region of the prostate gland. Here, from its situation, and the difficulty of applying the proper remedial agents, the disease is prone to lurk for an indefinite period, and often leaves as a sequel a permanent irritability and hypertrophy of the gland.

Gonorrhœal prostatitis arises, as its name implies, from the direct infection of gonorrhœal matter. This may occur in various ways. The urethritis may be so severe as to implicate rapidly, by extension of the inflammation, the deep as well as the anterior portion of the urethra; or the prostatitis may be produced by the use of instruments during an acute attack of gonorrhœa, they carrying with them the virus and depositing it in the prostatic portions of the channel. Again, it is asserted by some to be produced in the same manner by the use of injections. I believe this latter, however, to be a very rare cause of the disease, as the contraction of the cut-off muscles of the urethra which would be produced by the irritation of any liquid injected, is generally sufficient to make them the limit of the fluid. The most frequent cause is probably the first-named, as gonorrhœal prostatitis occurs only in those violently inflammatory cases of "clap" in which the morbid process would tend to spread rapidly.

The first signs of the extension of the inflammation to the prostatic region are a marked diminution in the quantity of the discharge, and an increasing desire to pass water, attended with much pain. This pain is very peculiar, somewhat resembling that occasioned by the presence of stone in the bladder, and is very characteristic of the disease. As the urine commences to flow, there is felt a sharp, cutting, burning sensation in the deep urethra; this increases, running down along the channel, until it reaches its point of greatest intensity at a spot on the under side of the urethra, in the penis, about three-fourths of an inch from the meatus. At the close of the act of urination, the muscular fibres of the bladder contracting upon the tender and inflamed prostate, give rise to the sharpest cutting and scalding pains.

As the disease increases, the calls to urinate become more and more frequent, and the patient is now obliged to relieve himself every ten or fifteen minutes. The urine is very acid, high-colored, and turbid, with a thick sediment of muco-pus. The stream is quite small, has very little force, and is apt to spirt out and scatter in all directions as it leaves the urethra: should there be much enlargement of the prostate, it will slowly escape drop by drop and partial retention ensue. If, with this condition of affairs, there is any implication of the vesical neck (which is not unfrequently the case), micturition is attended with uncontrollable spasms of violent straining, often accompanied with the passage of blood or bloody mucus. Otherwise there is not the same amount of vesical tenesmus which is present in acute cystitis, but the flow of urine is obstructed by the swollen gland, and the calls to urinate are frequent and urgent, simply because the bladder is never fully emptied of its contents, and a short time suffices for its distention. Sometimes, as before stated, complete retention of urine will result from the enlargement of the gland, requiring the use of the catheter. When this is introduced it meets with an obstruction in the prostatic urethra, and before entering the bladder its point deviates to one side or the other, indicating an enlarged condition of the gland in the opposite direction. Should the middle portion of the gland be affected, the introduction of the catheter may require some force, and, indeed, in some cases become impossible. Again, the normal curve of the urethra may be so much altered by the enlargement of the gland that a stiff instrument of the usual curve cannot pass into the bladder, and a Mercier's *sonde coudée*, or a flexible soft rubber catheter, will be requisite. The patient complains of a feeling of fulness in the rectum, causing a constant desire to defecate, although the bowels are constipated. In the more severe cases every attempt at urination, being followed by the straining

before alluded to, causes the involuntary evacuation of a small quantity of hardened fæces. These efforts are followed by sharp pains in the rectum, and there is constantly felt a dull, deep-seated, throbbing pain in the perineum, with occasional sharp exacerbations radiating outward from that region. Examination with the finger, per rectum, reveals a hot and enlarged prostate, very tender to the touch. Both rectal and urethral explorations cause much suffering to the patient. All these symptoms are attended with some constitutional disturbance, such as fever, headache, loss of appetite and sleep, restlessness, and irritability of temper. The patient is in a truly deplorable condition, for he can neither lie, sit, nor stand in any comfortable position, while the incessant and painful calls to urinate are sufficient to prevent him from sleeping, eating, or keeping quiet. This condition of affairs continues for a longer or shorter period of time. Sometimes in a few days resolution will take place, and the symptoms will rapidly subside, at the same time the discharge reappearing. At other times the process will go on to suppuration, and prostatic abscesses will result, involving either a part or the whole of the gland. This process is indicated by the pains becoming less throbbing and more of a lancinating character, and the occurrence of a sharp chill, or a series of rigors. When the abscess bursts, should it be into the urethra, it will be indicated by a discharge of pus, and the painful symptoms will immediately disappear. Should it, however, empty itself into the surrounding tissues, it may burrow among the tissues of the peritoneum, or still more rarely into the pelvis, giving rise to local and then general peritonitis; or it may point downward and outward, giving origin to permanent fistulæ. Sometimes, where the purulent material is small, it may never point, but with the subsidence of the inflammation be gradually absorbed, leaving behind a calcareous mass of a size proportionate to the quantity of pus which it represents. These concretions are rarely discovered until after death, and are not generally of a size to interfere with the functions of the gland. Should the whole of the gland be involved in the suppurative process, the result is fatal, the patient generally dying of purulent infection.

In other cases, instead of undergoing either resolution or suppuration, the inflammation may slowly pass into a chronic prostatitis, with a constant gleety discharge and more or less hypertrophy of the gland. These are the cases which so torment and baffle the urethral surgeon, as they are very rebellious to treatment, and require all the patience of both physician and patient.

The chief disease with which gonorrhœal prostatitis is apt to be confounded is acute cystitis arising from the same cause. It is extremely difficult, as a general rule, in acute cases arising from gonorrhœa, to make a positive diagnosis between these two diseases, as, owing to the continuity of surface, it is not long before the inflammation of a prostatitis extends to the neck of the bladder. The following table by Fournier will exhibit the main points of difference:

Cystitis of the neck of the bladder.	*Prostatitis.*
1. Characteristic *vesical* tenesmus; frequent and imperative desire to urinate.	1. Vesical tenesmus much less. *Rectal* tenesmus more marked.
2. Micturition especially painful with the passage of the last drops of urine, when there is a characteristic convulsive contraction.	2. Nothing similar.
3. Towards the close of micturition, excretion of a thick fluid,—a mixture of pus and blood; often also of pure blood.	3. Nothing similar.
4. Mere perineal sensibility; pains radiating towards the anus much less violent than in prostatitis.	4. Deep perineal pain, very acute, increased by motion, defecation, etc.
5. Prostate normal.	5. A very hard, sensitive prostatic tumor is felt on rectal examination.
6. No retention of urine.	6. Dysuria. Retention of urine.
7. Few or no general symptoms.	7. General symptoms marked; fever, loss of appetite, etc.

The prognosis of gonorrhœal prostatitis is generally favorable, although, should the inflammatory process extend to suppuration, the opinion should be more guarded, as fatal cases have frequently resulted.

Treatment.—The first and most important step in the treatment of gonorrhœal prostatitis should be rest in bed for

the patient; and he should distinctly understand that this is absolutely necessary in order to successfully combat the disease. In many cases there will be trouble in enforcing this, for, from the nature of the complaint, he is desirous of concealing his trouble from his family or friends, and hence may strongly object. The physician, however, should insist on his point, and, with regard to the feelings of his patient, administer a placebo to the family, stating that the sufferer has "kidney disease," or "gravel," which latter word will often cover a multitude of sins.

The diet should be of the mildest character, and should comprise milk, farina, corn-starch, soft-boiled eggs, etc., everything of an irritating or stimulating nature being avoided. I have found ice-cream to be very grateful and refreshing to the patient, and not to cause any after-disturbance. All acids and acid drinks must be forbidden, and the quantity of liquids allowed be moderate. No tea or coffee must be given; although a single cup of warm chocolate may be allowed in the morning.

The pain is sometimes much relieved by the hot sitz-bath, and during the interval the perineum may be covered with fomentations. In place of this orthodox treatment, the method recently proposed, of introducing small pieces of ice into the rectum, may be tried should the first procedure fail. I have, in one case in particular, given great relief to the deep throbbing pain in the perineum by the application of a large mineral-water bottle, filled with ice-water and loosely wrapped in a towel, placed between the legs and against the perineum.

The testicles should be supported in a suspensory bandage, so as to make as little strain on them as possible, and prevent the extension of the inflammation to the epididymis.

Internally, such remedies should be used as will render the urine bland and of a non-irritating character. The alkalies, potassa and soda, are mostly used, in the form of the carbonates and bicarbonates, the citrates, acetates, and tartrates. All these salts, when taken into the system, are decomposed, the alkali being liberated. These should be combined with anodynes, such as opium, hyoscyamus, belladonna, etc. A favorite prescription of Bumstead's is—

℞ Potassii bicarbonatis, ʒj;
Tincturæ hyoscyami, fʒj;
Mucilaginis, fʒvij.

M. et Sig.—A teaspoonful every four hours.

I have not derived as much benefit from this and several other standard formulæ as others may have done. I have used the following with great success in the treatment of the acute stage:

℞ Potassii nitratis, ʒij;
Morphiæ sulphatis, gr. ij;
Syrupi acaciæ, fʒj;
Aquæ camphoræ, q. s. ad fʒvj.

M. et Sig.—Tablespoonful every three hours.

The potassium nitrate acts as a cooling sedative to the bladder and urethra, producing slight diuresis, while the morphia and camphor diminish the constant desire to micturate.

To be properly successful in relieving the pain on urination, the urine must receive constant attention, and be always kept either neutral or slightly alkaline. For that purpose, it should be carefully tested for acidity each day with litmus paper, and the quantity of alkali varied accordingly. I do not think that the large quantities of diluent drinks, flaxseed tea, etc., constituting the regulation treatment of the text-books, are very beneficial, and am rather disposed to object to them; for, although the urine is diluted and rendered less irritating, yet the *quantity* is so much increased that the patient is caused to micturate much more often than is really necessary. It is much better, while not stinting the patient in his drink, to see that the quantity consumed is moderate, and then to administer a remedy which will render the urine alkaline without largely increasing its secretion. Such an agent may be found in the officinal liquor potassæ, but as ordinarily administered it will fail of its purpose unless given in very large doses. A method recommended by Prof. E. L. Keyes, in his recent work on venereal diseases, I have slightly modified and used with perfect success. It is as follows:

℞ Liq. potassæ, fʒss.

Sig.—Give ten drops in a half-tumbler of water, *three hours after each meal.*

When administered in this manner,—three hours after each meal,—the stomach being empty, the greatest amount of therapeutic effect is obtained from the least

amount of the drug. As medicines are usually taken by patients either before or just after a meal, the secretion of acid produced by the alkali is much greater, and the result of the drug upon the blood much diminished. This quantity—ten drops—will generally be sufficient to keep the urine neutral, although, should it still be acid, the quantity may be increased to fifteen or twenty drops without harm.

The vesical spasm is best counteracted by the use of rectal suppositories of ext. opii aq., gr. j; ext. bellad., gr. ¼, used every few hours. Should the belladonna disagree with the patient, two grains of extract of hyoscyamus may be used in its place. A still better formula is as follows:

℞ Camphoræ, gr. x;
Chloralis hydrat., gr. xx;
Morphiæ sulphatis, gr. ij;
Ol. theobromæ, q. s. ft. suppositoriæ no. x.

Sig.—One every three hours until spasm is relieved, then one night and morning.

I rather prefer gelatin to cacao butter as a basis for these suppositories, as it makes a more consistent preparation, not so liable to melt in the fingers. It is rather more difficult, however, for most physicians to obtain them of this material. I have found these suppositories also an excellent remedy in aggravated cases of chordee.

By the use of these three remedies, as above given, the patient can be kept comparatively comfortable until all acute symptoms are past. Should there be retention, it may be relieved by hot hip-baths, or a catheter should be regularly used every five or six hours and the bladder thoroughly emptied, as by this latter means the desire to micturate can be greatly avoided.

Much care should be exercised in the selection of the instrument, and one chosen which will give the least pain. The stiff metal catheter is very objectionable, as it generally requires force to pass it through the urethra closed by the swollen prostate, and it should never be used when it is possible to obtain another instrument. The English waxed cloth catheter is almost as bad, and so is the black rubber instrument of Delamotte, for they are not soft and compressible, and the eye is so sharply cut out as to catch in some of the mucous folds of the passage upon its withdrawal, and cause considerable irritation and pain. The best instrument for the purpose is undoubtedly the soft rubber, "velvet eye" catheter, made by Tiemann & Co., of New York, a cut of which is annexed.

VELVET EYE.

The eye of this instrument is perfectly smooth, the edges being bevelled, and consequently is not likely to catch on its withdrawal, and the softness and compressibility of the rubber render its use comparatively painless.

Should the disease terminate by resolution, all acute symptoms gradually disappear, and the discharge will again appear at the meatus. This should be assisted by the administration of the oil of turpentine, in doses of from five to ten drops three times daily, carefully avoiding the vesical irritation occasioned by too large doses. Or copaiba, or the oleoresin of cubebs, may be substituted in proper doses. This latter is highly recommended by Keyes, and I can testify as to its value. The patient must avoid all excesses and exposure for some time, as a slight cold will often produce a renewal of the acute symptoms.

Should the disease terminate in suppuration, and abscesses form, as soon as fluctuation can be felt by the finger in the rectum they should at once be punctured through the intestinal wall. Tarnowski and Didier prefer an opening carefully made through the perineum, so as to avoid communication with the rectum and the entrance of fecal matter into the cavity of the abscess. When the collection of matter points towards the urethra, it may sometimes be relieved by the introduction of a conical sound as far as the rectum, while a finger in the rectum presses the point of the instrument against the tumor. This operation requires great care, and should never be employed unless the symptoms are urgent. Where a large cavity in the prostate is left behind by the evacuation of an abscess, it may be washed out daily with a very short beaked silver catheter, having its eye near the tip, and after the washing injected with some astringent solution to stimulate granulation. A very convenient instrument for this purpose is one which I

will describe when speaking of the treatment of chronic troubles. Rectal and urinary fistulæ, should they occur, must be treated according to the laws laid down for such cases. After the abscess has once been emptied, relief is generally prompt, and a cure often results from the unaided efforts of nature.

The most annoying termination of gonorrhœal prostatitis is the chronic form. In this there is left, as a sequel of the acute affection, a hypertrophy of the gland, with chronic inflammation of its mucous surfaces and ducts and of the follicles and ducts of the sinus pocularis. This affection, designated by the elder Gross as "*prostatorrhœa*," is the annoyance of all urethral surgeons, for it does not readily yield to treatment. Its chief symptoms are dragging weight and pains in the perineum, increased by walking and sitting with the legs crossed, while any sudden jar or muscular exertion, such as taking an unusually long step or stepping down suddenly from a height, gives a marked increase of pain. There is a slight mucoid or muco-purulent discharge from the urethra, apt to be aggravated by a passage at stool, the patient usually believing the discharge to be semen. It does not contain semen, but is muco-purulent, full of fatty débris, leucocytes, epithelium, and often prostatic concretions. The frequency of micturition is more or less increased, the urine being expelled without much force and in a fine stream, the last drops often dribbling away, and the whole act attended with considerable urethral pain, felt particularly in the prostatic region. An examination with an instrument reveals great hyperæsthesia of the prostatic urethra, and after its use the symptoms of the patient are apt to be temporarily aggravated. Together with this there are many nervous symptoms, the patient being irritable, low-spirited, and despondent. Sexual intercourse is generally impossible, each act being attended with so much pain and aggravation of the symptoms as to deter the patient from its indulgence. Nocturnal emissions are not uncommon, being incited by the congested and hyperæsthetic condition of the gland.

The treatment of this affection is greatly aided by hygienic means, as the patient is generally debilitated from the effects of the previous acute attack. A moderate amount of exercise in the open air is to be advised. The diet should be nourishing, but not stimulating, and of such substances as will be neither difficult of digestion nor apt to leave a bulky residue of fecal matter. An essential point is that the bowels be emptied regularly, so that the contents of the distended rectum shall not press on the congested gland and thus aggravate the symptoms. The patient should, therefore, before breakfast every morning take a small glass of the Hunyadi János, Friedrichshall, or any other laxative mineral water, so as to keep the bowels in a soluble condition and cause from one to two evacuations daily. This will also tend to diminish the congested condition of the gland. He should sleep on a hard mattress, with no more cover than is absolutely necessary, and should be careful to empty the bladder before going to bed, so as to avoid as much as possible nocturnal emissions.

As a tonic having special benefit in this trouble, Bumstead speaks highly of the following:

℞ Strychniæ, gr. jss;
Acidi phosphorici dil., f℥iv.
M. Sig.—Teaspoonful three times a day.

The tinct. ferri chloridi of the U.S.P., in doses of gtt. xx three times daily, may be used to advantage.

The best results in treating this affection are undoubtedly obtained by the use of local remedies, applied either directly to the part, or indirectly by means of the rectum; in the latter place, from its close proximity to the prostate, the remedies having nearly as much effect. They may be used in the form either of a solution, or of rectal or urethral suppositories. Solutions may be applied by means of the deep urethral syringe, of which there are several different designs to be found at the instrument-makers'. The urethral suppositories may be applied to the desired part by means of an instrument which I have described at length in an article published in the *New York Medical Record* (December 25, 1880, p. 722), and which I will briefly mention here.

It consists of a canula ten inches long, the size of a No. 20 sound (Fr. scale), bent to a Thompson's curve, and graduated to a

scale of inches, commencing at the vesical extremity. Through this tube plays a flexible steel stilette, tipped with a probe-point, and forming, when fitted into the tube, a rounded and smooth extremity. To use the instrument, the stilette is slightly withdrawn, a suppository or short bougie placed in the extremity of the canula, so that about one-third will project from the end, and then the instrument, well oiled, passed gently into the urethra until the graduated scale shows it to have reached the depth desired. By a slight pressure with the stilette the suppository can be ejected into the urethra. The suppository or bougie to fit this instrument is about half an inch long, and can be made of either cacao butter or gelatin, medicated with the remedial agents I will presently mention. This method of procedure gives the benefit of a direct and prolonged action of the medicating ingredient.

It will sometimes happen that, owing to the highly-congested condition of the prostate, the urethra will not well tolerate the use of the instrument, and the suppository will be apt to act as a foreign body, and by its presence cause an aggravation of the symptoms. If this occurs, all instrumental interference must be stopped, and the gland allowed several days to regain its previous condition, being assisted, if necessary, by the effect of anodynes and sedatives, administered per rectum by means of suppositories.

Any of the following formulæ may be found useful:

(A) Ext. opii. aq., gr. j; ext. belladonnæ, gr. ½.

(B) Iodoformi, gr. ij; ext. belladonnæ, gr. ½.

(C) Iodoformi, gr. v; ergotini, gr. v; ext. belladonnæ, gr. ½.

(D) Morphiæ acet., gr. ¼; camphoræ, gr. j; chloral. hydrat., gr. ij.

(E) Ergotini, gr. v; morphiæ sulph., gr. ¼; ext. gelsem. fld., gr. v.

These will also form excellent adjuncts to a protracted course of treatment by the urethral suppositories, B, C, and E being extremely valuable in diminishing the congestion and hyperæsthesia of the gland.

With a view of successfully treating these particular cases, I have devised the following little instrument, taking my cue from an article by Dr. W. Thornton Parker, of Plymouth, Massachusetts, published in the *Boston Medical and Surgical Journal* for March 3, 1881. It has been very carefully made for me by Messrs. Tiemann & Co., of New York.

It consists of a tube of soft rubber eight and one-half inches long, the size of No. 14 Fr., terminating in a bulb the size of a No. 20 sound, Fr. scale. This bulb is perforated around its circumference with five small holes placed at the rear of the bulb and directed in such a manner that a liquid forced through the tube will be ejected backward in all directions. The orifice of the tube is made of such a size as will admit the end of an ordinary urethral syringe. This syringe is unnecessarily large for the purpose, and I find that the hard-rubber syringe No. 00, capacity

one-eighth ounce, made by the American Rubber Company, answers the purpose admirably. The softness and flexibility of this tube allow it to be passed into the most tender urethra with comparatively little pain, while the bulb and the backward direction of the stream prevent any portion of the injection from entering the bladder. When used, it is to be well oiled and slipped gently down the urethra until it reaches the affected region. The syringe, full of liquid, is next to be attached, and the injection forced gradually out by means of a gentle pressure on the piston. The presence of a fluid does not occasion the same amount of irritation here as does that of a suppository, and the instrument is consequently well adapted to those cases where the latter would be inadmissible. The quantity of liquid indicated by the capacity of the syringe—one-eighth ounce—will be amply sufficient; and even less may be used. This instrument, when used with a larger syringe, is well suited for washing out the prostatic urethra in the cases of abscess before mentioned.

I will now indicate some combinations of remedies which I have found to be particularly useful, and which can be used

either in the form of suppositories or as injections.

In cases with much pain and hyperæsthesia, but with little or no discharge:

(A) Morphiæ sulphatis, gr. ¼.

(B) Ext. gelsem. fld., gr. v; ergotini, gr. j; morphiæ sulph., gr. ¼.

(C) Ext. hyoscyami, gr. j; ext. belladonnæ, gr. ½.

(D) Iodoformi, gr. j; ext. belladonnæ, gr. ½.

(E) Acidi carbolici, gr. ½; liq. iodinii comp., gr. j.

In cases where there are both pain and free discharge:

(F) Zinci sulph., gr. j; ext. hydrastis fld., gr. ij; ext. belladonnæ, gr. ½; ext. opii aq., gr. ½.

(G) Zinci sulph., gr. j; ergotini, gr. j; ext. gelsem. fld., gr. v.

(H) Zinci sulph., gr. j; acidi carbolici, gr. ⅛; morphiæ sulph., gr. ¼.

In cases where there is not much pain and the discharge is of a mucoid character:

(I) Ext. hydrastis fld., gr. v.

(J) Zinci sulphatis, gr. j; acidi carbolici, gr. ⅛; ext. hydrastis fld., gr. v.

(K) Zinci sulphocarb., gr. j.

These injections should be made with a small quantity of warm water. The extract of hydrastis used should be made with a menstruum of glycerin and water, thus avoiding the irritating resin of the root.

By a steady persistence in this plan of treatment, accompanied with the occasional cautious introduction of a steel sound, some of the most hopeless cases may be benefited and often cured. The remedies I have above indicated are but an outline of those that can be used, and which will commend themselves to the use of the physician.

The nitrate of silver, in the form of a concentrated solution (twenty to forty grains to the ounce of water), of which from five to fifteen drops may be used, has been considered by some very high authorities as a valuable remedy, but its action is very harsh, and I am inclined to leave it as a *dernier ressort*.

839 Race Street, Philadelphia.

Billroth's Latest Operation.—The *British Medical Journal* says that Billroth recently did another resection of the pylorus, and also burnt off a piece of the liver with Paquelin's cautery. This piece of liver was inseparably adherent to the carcinoma. "So far all goes on well," said the professor, four days later.

ALCOHOL: ITS THERAPEUTICAL USES, INTERNALLY AND EXTERNALLY.

Read before the Philadelphia County Medical Society, April 27, 1881,

BY ROBERTS BARTHOLOW, M.D.

OF the general subject—alcohol—there has been assigned to me for this discussion its therapeutical uses, less the uses of malt liquors.

I have, therefore, to consider alcohol in the form of spirits,—whisky, brandy, gin, etc.; of wines, still and sparkling, light and heavy, sweet and dry, grape-juice and artificial, pure and fortified, etc. All of these agree in the presence of alcohol in varying proportions, but differ in respect to certain constituents, natural or factitious, and peculiar to each variety. It is obvious, therefore, that the question of the uses of alcohol is complicated by the numerous forms and combinations in which this substance enters the organism of man. In the short time allowed me I can do no more than present a syllabus of the subject,—state, merely, a series of propositions.

Alcohol may be used as a stomachic tonic and to increase the activity of those functions included under the primary assimilation, as a cardiac and arterial stimulant, as an antipyretic, as an antiseptic, as an anodyne, and as a styptic and astringent. Besides these points we must consider whether it shall be given or withheld in mania a potu, or acute alcoholic delirium, and in delirium tremens. The subject may be best studied in this order.

I. As a stomachic tonic alcohol is effective only in the case of those not habituated to its use. As pepsin is not only precipitated by alcohol from its solution in the gastric juice, but is also rendered inactive as a ferment, to employ this agent as a means of promoting digestive activity is apparently paradoxical; but the explanation lies in the fact that it is a concentrated solution which acts thus on the pepsin. We obtain two points of practice from this statement,—to give alcohol properly diluted; to stimulate digestion, administer the remedy immediately before meals: for the action of alcohol as a stomachic tonic consists in the power it has to cause a prompt congestion of the mucous membrane, and the increased activity of the gastric glands is a necessary consequence. That in time a catarrhal state of the mucous membrane is pro-

duced, and a pathological secretion obtained, shows us the impropriety of the long-continued use of alcohol as a stomachic tonic, and explains why such a therapeutical effect is not the result of its administration in the subject of alcoholism.

In the atonic dyspepsia of the sedentary and the feeble digestion of the convalescent, alcohol is useful in a high degree. The particular form of the remedy must vary with the peculiarities of each case. A wine of good body and decided bouquet has been found very efficacious in the weak digestion of literary and nervous sedentary persons. In the case of the convalescent, a spirit is preferable to a wine, and whisky or brandy is prescribed according to individual tastes, partly, and the state of the intestinal canal,—the former having a somewhat laxative, and the latter astringent, action. The quantity taken is determined by several considerations,—by the amount of stimulation beneficial to the organs, by the effect as manifested in the circulatory and nervous systems, and by the degree of elimination. To the literary and nervous invalid class, the wine proposed is especially grateful, and they are responsive in a high degree. As the wine is to play the part of both stimulant to the digestive organs and a food of the nervous tissue, the best results are had from a generous wineglassful taken during the principal meal. The kind of wine selected is determined by several considerations. If the organs simply require stimulation, a good, dry sherry or Burgundy may be best adapted to the case; if an excess of acid be present, due to the fermentation of the saccharine and starchy foods, a sweet wine is objectionable, but then an acid Rhine wine of high alcoholic strength—as, for example, the Forster Riesling—may be serviceable in a remarkable degree. For the weak digestion of convalescence, it is well known that a considerable quantity of spirit is borne well and required. In both groups, but in an especial degree in the nervous and depressed invalid, the effect of alcoholic stimulation is peculiarly grateful and seductive: hence the danger of the alcoholic habit, and the need of circumspection in prescribing a remedy which may be so abused.

When alcohol is used to promote the nutrition in general, it should be administered during and after meals, to obtain at the same time the effect due to stimulation of the gastric glands and the force derived from the oxidation of the remedy, whence it becomes in a certain limited sense a food. The amount required in wasting diseases—as in chronic suppuration and in phthisis—will be more, and it will be better borne, than in other chronic maladies of a depressing kind; but in all chronic maladies the amount required is limited by two facts: 1. A small quantity will stimulate the digestive organs without injuring the pepsin; 2. Only a small quantity can be oxidized, and therefore utilized as force. It follows that it is useless to attempt, by increasing quantity, to overcome the inertia of the nutritive functions. Anstie, in the course of his well-known researches on the disposition of alcohol in the organism of man, found that beyond a certain small amount,—two or three ounces of absolute alcohol,—that which is taken is eliminated unchanged.

Applying these principles to phthisis,—which may serve as an example of a large group of maladies,—we may consider how and to what extent alcohol may be used in this disease. A notion prevails more or less widely among the laity, shared to some extent by the profession, that alcohol is in a certain sense a prophylactic and curative agent in consumption. By some physicians, amylic alcohol is held to possess these powers. That these notions are not well founded is proved by the fact that so many subjects of chronic alcoholism die of phthisis. That beneficial results are obtained by the judicious use of alcohol is equally true. The questions for us to consider are, how much alcohol is necessary, and what are the conditions of its use in consumption. The principles which I have already laid down are perfectly applicable. It is an axiom that when alcohol improves the appetite and increases the body-weight it is doing good. The quantity of alcohol sufficient to stimulate the gastric glands, and yet short of the strength necessary to precipitate the pepsin, is the proper quantity. As the alcohol eliminated by the various channels of excretion is in excess of the oxidizing powers of the organism, no benefit can result from such a quantity. It is obvious from these considerations that the best results are derived from half an ounce to an ounce of whisky or brandy, taken during or immediately after meals; for thus the stomachic tonic effects

and the force-value of alcohol as a food are obtained. The now almost universal use of whisky with cod-liver oil is based on sound principles, unless, as is sometimes done, the mixture is given an hour or two before meals, which must have a disastrous effect upon the appetite and the digestion.

That there is any specific action of alcohol in consumption—that alcohol has an influence apart from its stomachic tonic effects and as a hydro-carbonaceous food—cannot for one moment be entertained. We may therefore dismiss the purely groundless assumption that amylic alcohol has some special virtues.

The use of alcohol in acute wasting diseases must come up hereafter.

In certain diseases of the digestive tube, alcohol in its various forms is highly useful. All the world knows that sometimes obstinate vomiting, not dependent on inflammation of the stomach, may be promptly checked by a tea- to a tablespoonful of raw brandy. In the vomiting of uræmic intoxication, and especially of yellow fever, a dry champagne or our native sparkling wine may be very successful. A simple diarrhœa may be checked by brandy. Not to waste time in the recital of these trivial and well-known therapeutical properties, I pass on to the fact that in cholera infantum we have in brandy the most generally efficient curative agent. It is generally known, I believe, that infants bear a relatively larger quantity of alcoholic stimulants, but it is not known that large doses of brandy are singularly efficacious in the disease just mentioned. I have given half a teaspoonful to a teaspoonful of cognac brandy every three hours to a child under one year, and above that to three years one to two teaspoonfuls. It should not be given with milk, but in water as warm as possible, and as remote from the time of food-taking as possible.

II. As a cardiac and arterial stimulant, alcohol is probably more frequently used than for any other purpose. It may be well entitled "the remedy of paradoxes." It is employed in states of depression to give warmth to the surface and to increase the action of the heart and arteries, and in states of excitement of the vascular system and elevation of temperature it is used to lower both. This seeming paradox is readily explained; but the explanation must be reserved.

Alcohol is indicated when from any cause the action of the heart and of the arterial system is depressed suddenly and powerfully. The sudden failure of the heart from moral causes, from shock, from hemorrhage, from weakness of the cardiac muscle, are conditions in which alcohol is indicated, and in which it is used with advantage. There are two explanations of its power to elevate the heart and the vascular tension. The first is reflex. It is within the range of everybody's experience that as soon as a tablespoonful of whisky or brandy reaches the stomach the heart at once moves more rapidly,—that is, the impression made on the end organs of the pneumogastric in the stomach reaching the pneumogastric nucleus, the inhibition exercised by the nerve relaxes, and the accelerator apparatus exercises its power with lessened hindrance. That this explanation applies with much probability is rendered more certain by the fact that the action of the heart is simply increased by alcohol; in other words, that the diastolic interval is shortened by its influence. The second explanation of the power of alcohol to increase the rate of the heart's movements is that by its oxidation force is generated, which is utilized by the cardiac ganglia. There are other substances, of course, which also yield force; but alcohol has the distinct advantage that its combustion occurs with more readiness than any other available substance. But we shall find hereafter that alcohol in large quantity depresses the circulation. Now comes the explanation of the apparent paradox. Whilst small doses stimulate the circulation, large doses have the opposite effect; therefore, our conclusion is, to overcome cardiac depression the stimulant must be administered in small quantity, but frequently. In many cases, a wine of good body, highly charged with œnanthic and other ethers, is preferable to a spirit.

At this point we should endeavor to arrive at some positive conclusion in regard to the administration of alcohol in preparation for the apprehended cardiac depression of the anæsthetic state, or to relieve it. Prof. H. B. Sands, M.D., of New York, has followed the practice for several years of inducing alcoholic intoxication as a preparation for the administration of ether or chloroform and to prevent shock. It is always inculcated to administer an ounce or two of whisky as a preliminary to the anæsthesia and to the

operation. This may or may not be good practice. It is good practice if the heart is sound and the full anæsthetic state is desired; it is bad practice if profound and protracted anæsthesia is not necessary, and if any cardiac weakness exist; for, alcohol being the source whence the anæsthetics are obtained, and a congener as regards their action on the nerve-centres and on the vascular apparatus, it must intensify their effects. The theoretical deduction is abundantly confirmed by clinical experience. In a recent discussion before this Society, our learned colleague Dr. Turnbull strongly criticised the subcutaneous injection of alcohol in the case of lethal symptoms caused by ether, and he was sustained by the eminent therapeutist Prof. H. C. Wood, and myself.

To inject brandy or whisky subcutaneously with a view to stimulate the respiratory and cardiac centres in chloroform or ether narcosis is therefore improper,—contributes, indeed, to the fatal result.

III. The antipyretic effects of alcohol involve more doubtful questions than those therapeutical effects heretofore considered, but the weight of authority is unquestionably in favor of the view that alcohol in large doses depresses the temperature. It is not my province to discuss the physiological data on which modern scientific opinion rests, but the practical considerations governing its use in disease. I start with the proposition—the elements of which are too often confounded—that the antipyretic effects of alcohol are distinct from its stimulant and supporting properties. In the treatment of acute inflammations and fevers we may employ alcohol as an antipyretic, to depress the abnormal temperature, or as a support to the circulatory system and a stimulant to the digestive function. In the former case large, in the latter small, doses are necessary.

The modern conception of the fever-process and the relation of high temperature to cardiac and cerebral paralysis have imparted a new and more powerful significance to the use of antipyretics. It may be compendiously stated, without going into the reasons for the statement, that alcohol does not compare with the cold bath, with quinia, even with digitalis, as an antipyretic. It is true Binz has apparently demonstrated its utility in the hyperpyrexia of pyæmia, but this fact does not invalidate the general proposition. There can be no question, however, regarding the utility of alcohol in the adynamic state in fevers and in inflammations. It is not, however, as a febrifuge, as a depressant of the temperature, as an antipyretic, that it is useful. It may be affirmed that in all cases of the feverish state, if digestion still goes on, if cardiac paralysis is not threatened, alcoholic stimulants are unnecessary. The two conditions demanding the administration of alcohol are failing digestion and failing heart. It is rare indeed that more than two ounces of wine or an ounce of whisky is required, even in the most pronounced adynamia. If this do not stimulate the stomach to better work, or itself furnish needed force to the failing heart, a larger quantity can do no more. How often do we see the stomach filled to overflowing with stimulants, and yet the heart does not respond, because the smallest amount is not appropriated! When a thimbleful cannot be oxidized, why put into the stomach a pint? Graves formulated some admirable rules for our guidance in the use of alcoholic stimulants in fevers. Alcohol does good when the tongue changes from dry to moist, when the stomach can receive and digest more food, when the pulse declines in rapidity and gains in force, when the surface grows moist and cool from hot and dry, when the delirium ceases and an expression of intelligence replaces blank stupor.

In the event of sudden and alarming depression, digestion being suspended, it is possible to maintain the body-forces on alcohol alone. Very numerous examples confirm the conclusions of experiment, that the oxidation of alcohol furnishes the force necessary to maintain the vital operations for a number of days; but it should be definitely understood that in the administration of alcohol for this purpose no provision is made for the necessary processes of wear, and hence there must early come a termination to a life so maintained.

IV. Some recent experience justifies the belief that the antiseptic properties of alcohol may be made available in practice. That it is inimical to animal ferments, to the lower forms of life, and prevents or arrests putrefactive decomposition, are well-known facts. That these properties may explain the effects of full doses of alcohol in diphtheria seems probable, for, besides its influence over the cardiac depression, the micrococci colonies may be attacked

by it as they migrate. In what way we may explain the results, it seems plain that alcohol, when pushed to a degree which seems somewhat extravagant, has appeared to exert a decided curative influence which cannot be explained by its stimulant and antipyretic action. From this point of view may be regarded the good effects of alcohol in the septic maladies,—septicæmia, erysipelas, puerperal fever, and the exanthemata, notably smallpox. It seems to me beyond question that the undeniably good effects of alcohol in these septic diseases is not explained by referring the results to its other properties. If this be admitted, it follows as a necessary consequence that to be effective in these diseases alcohol must be administered in large doses. There must be maintained, in a certain sense, a saturation of the blood in order to act on the *materies morbi* efficiently. There must be, of course, a judicious measure of the force of the disease, and the doses of the remedy be made to conform. In my own experience I have found these principles a valuable guide to the treatment of this important group of diseases.

V. I need not detain you long on the subject of alcohol as an anodyne. It quite yields in importance to the valuable derivatives ether, chloroform, chloral, etc. It has probably yielded quite too absolutely to the anæsthetics so called, and might be used advantageously to benumb the sensibility to pain in the minor operations. It cannot be prescribed with safety for the relief of nerve-pain, since the alcohol habit is sure to be formed. As a temporary expedient it may be useful. A tablespoonful of raw brandy or whisky may arrest an attack of migraine impending. An anæmic headache or the wakefulness of anæmia may be quickly removed by alcoholic stimulation. It is a curious fact, true also of morphia, that when after the long-continued use of spirit for neuralgia the remedy is discontinued the pain returns.

VI. What is the proper practice regarding the administration of alcohol in certain maladies caused by it? To render my position perfectly clear I must precede the answer to this question by some definitions. Magnan makes a distinction between acute alcoholic delirium and delirium tremens,—the former a delirium due to the impression of alcohol on a brain not accustomed to it; the latter a delirium occurring in the subject of chronic alcoholism. In my "Treatise on the Practice of Medicine" (2d ed., p. 843) I have adopted the old but expressive terms *mania a potu* and *delirium tremens*,—the former corresponding to Magnan's acute alcoholic delirium. I must insist on the distinction between these forms of alcoholic delirium; for the practice pursued is a necessary consequence. Now, as in mania a potu the delirium is a direct result of the alcoholic excess, the first step in the cure consists in the withdrawal of the alcohol. The practice should be different in most cases of delirium tremens. It is true, in a small proportion of cases the outbreak of delirium is due to sudden excess, but usually the opposite condition obtains. Owing to the failure of the stomach, neither food nor stimulant can be retained, and then the peculiar illusions and hallucinations appear. In such cases, also, the food, when the stomach is prepared to receive it, may fail to be digested, because the gastric glands, so long accustomed to the stimulation of alcohol, will not act in its absence. It is surprising how in these cases, after some preparatory treatment, when food is taken with more or less stimulant, sleep and sanity follow expeditiously, without the intervention of doubtful hypnotics.

Alcohol performs another rôle in those cases of delirium tremens complicated with croupous pneumonia, or cases of croupous pneumonia complicated with delirium. With the progress of the pulmonary obstruction, ischæmia of the arterial system increases, and hence the laboring heart needs the support which alcohol may supply. Thus, having correct principles to guide our treatment of delirium tremens, the vexed question of the use of alcohol in this disease is readily solved.

VII. The power of alcohol to coagulate albumen, to suspend the activity of the unorganized ferments, and to destroy minute organisms, lies at the foundation of its external uses. It is a most efficient hæmostatic to restrain bleeding from wounded surfaces, as I have repeatedly verified. As an antiseptic dressing to wounds, to prevent the entrance of the germs of putrefaction, to check suppuration, and to promote healing, it has in my experience scarcely been inferior to the much-vaunted carbolic acid. It is

an efficient means for procuring local refrigeration of an inflamed joint or swelling. Injected under the skin in the neighborhood of painful nerves, it has no inconsiderable anodyne power. This property may be utilized for the relief of myalgia and lumbago. A few drops thrown into the affected tissues will usually afford permanent relief. It is more efficient than water, used by the method now known as aquapuncture. Enlarged tonsils, hypertrophied thyroid, and glandular swellings may often be slowly reduced and made to disappear by the parenchymatous injection of alcohol. This method is applicable to the treatment of uterine fibroids.

In cases of sudden depression of the powers of life, whisky may be thrown under the skin, to obtain more speedily than by the stomach its effect as a cardiac stimulant. I have already mentioned the contra-indication of this practice in the treatment of the narcosis or the cardiac depression caused by the anæsthetic agents ether and chloroform. It is, however, perfectly applicable to other conditions characterized by sudden and powerful depression of the heart. The amount injected varies from ten minims to a drachm; a syringeful—about half a drachm—is usually inserted at once, and is repeated according to necessity. Some local swelling arises, which may subside in a day or two, or an indurated lump remain for a time, or rarely suppuration may occur.

MEDICAL RELATIONS OF THE COMMERCIAL ADULTERATIONS OF WINES AND LIQUORS.

Read before the Philadelphia County Medical Society, April 27, 1881,

BY HENRY LEFFMANN, M.D.,

Lecturer on Toxicology in Jefferson Medical College.

GENTLEMEN,—In an article read before this Society just one year ago,* I said that the commercial adulterations of wines and liquors are mostly by substances that are not more harmful than the materials which they substitute, and that while much liquor is factitious it cannot be considered more injurious than the genuine. I have seen no reason in the year's interval to modify this view, and in the present paper I shall confine myself to a brief notice of known effects of those substances which, either by accident or design, find their way into common liquors. Medically considered, the circumstances under which a body is added are of no importance: the fact that it is found in the liquor makes it a commercial adulteration. We may consider the different substances, under a rude classification, according to their chemical similarity.

First: Alcohols other than the common form. The vinous fermentation gives rise to a number of by-products, especially to related members of the simpler alcohol series,—propyl, butyl, and amyl alcohol. Methyl alcohol, or wood-spirit, is not usually found. As regards propyl and butyl alcohol, our knowledge of their effects is not extensive; but their poisonous qualities are affirmed by good authorities, and they appear to have marked depressing action. Fusel oil or amyl alcohol is the great impurity of fresh liquors. Its complete removal is difficult, and its action is decided. When inhaled in concentrated form it is strikingly irritating to the fauces; when diluted with common alcohol it is more tolerable: but authorities are agreed that its effects are dangerous and prolonged. The following are some of the recorded facts concerning its action.†

Eulenberg administered ten drops to a small animal, with the production of violent palpitation in seventeen minutes, and anæsthesia in twenty-two minutes. The animal did not completely recover until next day.

Cros, of Strasburg, experimenting on himself, found that ten to fifteen centigrammes (about two minims) produced frontal and temporal headache, with constriction of throat; four grammes (f℥j) caused general depression, with difficulty of standing and diarrhœa; eight to sixteen grammes, jerky, rapid respiration, with marked head-symptoms and repeated vomiting.

Rabuteau found that ten centigrammes dissolved in one litre of beer produced dryness of throat and a sort of "horrors."

As regards the amount in whiskies, Cameron, of Dublin, thinks that bad samples may contain from .1 to .3 per cent.

A French authority (Dujardin-Beaumetz) has given the following as a scale of the

* Transactions of Philadelphia County Medical Society, vol. ii. p. 28.

† See Dublin Journal of Medical Science, 1880, lxix. 414–422.

proportion between the poisonous doses of these alcohols:

Ethyl alcohol . . .	8
Propyl " . . .	3·9
Butyl " . . .	2
Amyl " . . .	1.7

Cameron thinks the figure for amyl alcohol too great, and believes this substance to be at least fifteen times as active as ethyl alcohol.

Methyl alcohol is not a common adulteration. Its effects appear to be less serious than those of common alcohol. Richardson, in his essay on alcohol,* speaks positively of the lightness and transient character of its effects, and seems to recommend its use medically. Statements of the poisonous character of its vapor have been published; but I may mention that for some five or six years past I have worked in an atmosphere more or less impregnated with the vapor, and have felt no injurious effect.

Among the incidental products of fermentation and distillation are aldehyde and empyreumatic oils. Cameron, in a recent report, inclines to refer the poisonous effects of new liquors to the aldehyde rather than to the fusel oil, which is commonly supposed to be the cause. He mentions analyses in which considerable amounts of aldehyde were found, and details a case in which an aldehyde whisky caused serious mental derangement. This impurity is removed by evaporation and oxidation, and Cameron advises that no whisky be allowed sold unless it is at least two years old. This period, by the way, is the same as was given by Dr. C. H. Thomas in a discussion before this Society some months ago.

The empyreumatic oil probably contains creasote-like bodies. Two or three drops are said to cause burning pain in the stomach, while more than four minims could not be borne.

The odors and some of the medicinal effects of wines especially are due to small quantities of the so-called compound ethers, which are formed by the union of an alcohol radicle with the radicle of some acid. Out of the large number of possible compounds of this class, we are here concerned only with those which are formed from the common alcohols,—such as methylic, ethylic, and amylic,—and the common organic acids, formic, acetic, and valerianic. Nearly all the members of the group are highly volatile and strongly odorous, freely absorbed by the system, and rapidly eliminated. Their rate of absorption and elimination diminishes as the proportion of carbon increases, and the higher members of the series are like the common fats. Those which occur in wines and liquors are mostly capable of being made artificially, and are frequently so prepared, so that by being added to a pure spirit a false wine can be made. The medical effects of these artificial flavors must be regarded as similar to the natural form. Considerable light has recently been thrown on the medical relations of the more common forms of these bodies by the researches of Rabuteau. He experimented upon himself and upon various warm- and cold-blooded animals. He found the effects much more decided in the latter class, and ascribes this to the less rapid change and destruction of the ether in the blood. This change, Rabuteau proved by experimenting upon blood-serum, consists in the action of the alkaline salts of the blood to produce an alcohol and a sodium salt. Thus, if acetate of ethyl be introduced into an alkaline fluid, we will have ethyl alcohol and sodium acetate. The ethyl alcohol will produce its constitutional action; the sodium acetate will be converted into carbonate and removed in the urine. I have been somewhat minute in giving these chemical points, because by properly applying them we have a clue to the medical relations of all the flavoring ethers. Their action depends on the alcohol radicle, and not on the acid present. Whatever acid is present will soon pass into carbonate, but the alcohol radicle will form its corresponding alcohol, and the effect of this will be the ultimate effect. Applying this principle, we will understand why the French experimenter found that ethyl acetate, ethyl formate, and ethyl valerianate had actions very similar, and when added to good wine did not materially modify its properties. These bodies, by the action of the blood, were changed into ethyl alcohol and sodium acetate, formate, or valerianate, as the case might be; and these three salts were rapidly changed into carbonates. When the corresponding compounds of amyl were taken, the dangerous amylic alcohol (fusel oil) was soon produced. It thus happens that two bodies

* Cantor Lectures, 1874.

of the same absolute composition may produce different effects. Amyl formate and methyl valerianate, for instance, have the same composition; but one will produce the volatile and rapidly-eliminated wood-spirit, the other the persistent and poisonous fusel oil.

Rabuteau gives, in more or less detail, the effects of a number of these ethers; but it is not necessary to do more than indicate a few points. Two wineglassfuls (about eight ounces) of a ripe wine, to which 1.5 per cent. of ethyl acetate had been added, taken during a morning, produced no special effects beyond a slightly increased tendency to affect the head. White wines usually contain this ether, and they are said to have a tendency to produce head-symptoms. The ethers formed from amyl and propyl alcohol are supposed to be especially powerful in causing the conditions and changes seen in chronic alcoholism.

Quite a long list of spurious colors, bitter and astringent principles, have been given by the writers on the chemistry of this subject.

Among the colors added to wine are logwood, red cabbage, beet-root, caramel, cochineal, and rosaniline. It is only with regard to the last-mentioned that anything special may be said. Aniline preparations are very apt to contain arsenic, and, while the color itself may have very little injurious action, the danger of arsenical contamination should justify the active prohibition of its use.

Of the bitter principles added to beer I may mention absinthin, aloin, gentianin, and quassin. According to some observers, absinthin is a cerebral excitant; according to others, a pure tonic. It is used in continental-European practice in doses of one-half to two grains. I have no data showing the percentage used in beer, but it is probably small. The medical relations of the other bitters are well known. It is doubtful whether, in the proportion in which they are used in beer, they could produce any trouble.

A number of miscellaneous adulterations may be briefly touched upon. Glycerin is employed to substitute syrup in some wines and spirits. For the purpose of giving to liquor the peculiar property of holding a bead or bubbles, a so-called bead-oil is used. One sample which I examined consists apparently of fixed oil; but, as only about three-quarters of an ounce are added to forty gallons of spirit, the adulteration cannot be considered dangerous. Sugar of lead, plaster of Paris, and alum have been found in wines, but not commonly. Their presence would undoubtedly be injurious, the use of the first-mentioned being entirely improper.

In conclusion, I feel compelled to express an opinion that may seem to many unreasonable. We know that liquors prepared by strictly natural methods are not constant in composition; we know that, under the exigencies of trade, additional conditions of variations are produced, and even complete substitution brought about. I have for some time thought that the best way to secure entire constancy in the therapeutic use of alcohol would be to have the preparations made up by regular prescription, or by printed formula in the Pharmacopœia. The substances which exist in a wine, a beer, or a brandy are in accidental mixture; some are useful, others useless. Why should we not have the useful articles properly combined by competent hands, and the useless omitted? The prejudice is in favor of the natural liquor, the opposition strong against the factitious article; but this prejudice and opposition are probably due largely to conservatism. If the use of alcoholic liquors continues much longer in medical practice, and the physiological and therapeutic effects of their ingredients become pretty fully known, we may expect that the physician, instead of ordering a special wine, will simply prescribe such proportions of alcohol, water, flavoring ethers, and astringent or bitter principles as may seem required.

AN ADDITION TO THE BINAURAL STETHOSCOPE.—Mr. Irwin Palmer figures, in the *British Medical Journal* of April 30, an addition to the binaural stethoscope in the shape of a dial-plate which registers the divergence of the metal arms, thus enabling the instrument to be used as calipers to measure various diameters, expansion of chest, etc.

IS ALCOHOL A FOOD?—WHEN SHOULD MALT LIQUORS BE PREFERRED TO WINES AND SPIRITS IN THE TREATMENT OF DISEASE?

Read before the Philadelphia County Medical Society, April 27, 1881,

BY H. C. WOOD, M.D.

BEFORE attempting to express briefly an opinion as to the food-value of alcohol, and to marshal the facts upon which such opinion rests, it is proper to define the term "food," lest verbal confusion arise. Some persons may incline to recognize as foods only those substances which either in their entirety or in a more or less altered condition are capable of being formed into the bodily structure. It is plain, however, that this use of the word is too restricted. Of the substances taken daily into the stomach as sustenance only a portion becomes an integrant part of the animal economy, as is shown by the enormous increase in the formation of urea which follows a heavy meal of meat. The appetite for blubber which is produced by exposure to an Arctic atmosphere indicates that the system needs an extra supply of fatty food,—an indication confirmed by the beneficent effect upon the exposed organism of a highly carbonaceous and liberal diet. The Arctic explorer does not fatten, although he may eat enormously of fat. The carbon compound is evidently fuel which is burned up to maintain the bodily heat,—*i.e.*, to yield force to maintain the molecular movements of the organism. It is not necessary to elucidate the point further. It is plain that under many circumstances that which is eaten is used not for reconstruction, but for force-production.

If the term food be employed in its narrower and, as I think, improper sense, it must be acknowledged that there is no proof that alcohol is a food. The enormous accumulation of fat frequently seen in beer-drinkers, and to a less extent in those who employ dilute alcohol in other form, would seem to indicate that alcohol is capable of being converted into fat, but is probably better explained in other ways.

When the term food is used in its wider and more correct sense, the question "Is alcohol a food?" must receive an answer essentially different from that just given.

From this point of view, any substance which is destroyed in the system, and during the destruction yields force, is a food. The evidence that alcohol fulfils both these conditions is most positive,—so positive, indeed, that there is probably no one of those present that would deny at least that alcohol is burnt up in the body; and, if it be burnt up, it must yield heat,—*i.e.*, force.

The questions whether alcohol is an economic food, whether it is practically useful as a food, are entirely distinct from that just answered. In regard to its economy, an ounce of good whisky may be estimated to cost about three and one-half cents to the man who buys by the gallon. According to the researches of Dupré, it would require about five ounces of lean beef to yield the same amount of force as that produced by the ounce of alcohol: these five ounces may be fairly estimated as costing at least five cents to the ordinary consumer; so that the advantage is plainly on the side of the spirit. There are, however, various foods cheaper than is lean meat. Tallow at six cents a pound in its burning certainly affords much more of force for the money than does alcohol.

Looking at the matter practically, and not as to a theoretic economy, it is evident that, as alcohol is usually taken and as food is usually eaten, no claim can be rightly made as to the superior cheapness of the beverage. Again, it is notorious that in America almost every one in reasonable health consumes much more food than the system needs, so that any alcohol taken is added to that which is already in excess. In Europe it is different: a large part of the population is underfed, and a modicum of alcohol is a decided food-gain. It must be remembered, also, that as a food alcohol is superior even to lean beef, in that it requires no force to digest it. The coarse food of a European peasant is often worked up by the stomach only by the expenditure of much force; it is also repulsive to the palate. The draught of landwein or the schooner of cheap beer washes down very well the morsel of black bread. Not only by stimulating the stomach does it aid in digestion, but also by readily yielding force to the system it assists in the elaboration of more refractory substances.

Although I hold that the habitual use of alcohol is to well-fed persons not only unnecessary but positively harmful, it seems to me that in many cases of illness and in

those periods of life when by reason of age the body waxes weak, alcohol is possessed of great value. Under sixty years of age the daily employment of wine may for most persons be very well discountenanced; but after this period has been reached, I believe the moderate employment of stimulants is very useful. The progressive failure of bodily powers points to the use of a substance which shall aid in digestion and readily supply force. In the later years of life even the narcotic influence of alcohol is of value, easing the restlessness, the slight discomforts, the suffering of nerve-failure incident to failing vitality.

The question whether alcohol has food-value in disease is one not easily answered by positive evidence, because the narcotic properties of the substance are so marked as often to mask its influence as a food, and because we rarely dare to employ alcohol except with an abundance of other food. The principles already outlined are, however, as applicable in disease as in health. Recent researches in fever have determined that the excessive heat-production is dependent upon excessive changes in the stored materials of the body, and it is improbable, though not impossible, that alcohol is capable of taking the place of these, and, by being, as it were, vicariously burnt, saving the tissues. The value of alcohol in low fevers therefore probably depends upon other qualities than its usefulness as a food, although our knowledge of fever-processes is yet so imperfect that it is necessary to speak with great reserve.

In chronic wasting diseases I believe alcohol has an actual food-value, besides being a most powerful aid to the digestion of other food. Arguments upon this point do not seem required, and it is of course very difficult to give actual clinical proofs, because we always employ alcohol with other foods and remedies.

The question as to the best method of administering alcohol when it is used for its sustaining powers is of vital interest.

Two general propositions will, I believe, command almost universal assent. First, the alcohol must be given in a dilute form; second, it should be given along with other food. Provided these two rules are observed, I do not think it makes much difference in what form the drug is administered. In chronic diseases malt liquors have both advantages and disadvantages. They represent food and drink, are less apt to be abused than are stronger liquids, and by virtue of their bitterness have some tonic properties; on the other hand, they sometimes disagree with the stomach. As they contain some nutritive material, there is perhaps more tendency to administer them apart from food than there should be. The amount of solid constituents in a pint of malt liquor varies from over two and a half ounces of dry residue in the strongest English ales to three-quarters of an ounce in the weakest ales and beers. The ales and beers usually drunk in this city probably range from one to two ounces of solid contents to the pint. The nature of much of this solid matter is not known, but albumen, bitter and resinous principles from the hop, earthy salts, grape-sugar, glycerin, and a number of complex acids have been recognized in it. The tendency to grossness seen in beer-drinkers undoubtedly largely depends upon the solid constituents of the beer which is taken, and seems to me to indicate the proper medical use of malt liquors,—namely, that they are especially to be employed in wasting diseases, *i.e.*, where there is a tendency to the loss of the bodily fat.

In regard to the choice of malt liquors, I do not think there is any other than what we may call personal grounds for selection. That which suits the palate best usually suits also the stomach best. The choice should always settle upon the ale, porter, or beer which can be used with least inconvenience to the stomach; and when all malt liquors produce "biliousness,"—*i.e.*, gastro-intestinal derangement,—wine or diluted spirits should be substituted. As the malt liquors contain nutritive material, it is less necessary to give food with them than it is with whisky or wines. Nevertheless, it is preferable in most cases that food should be taken with the ale or beer.

PISTOL-SHOT WOUND OF SIDE AND ABDOMEN.

BY HENRY M. WETHERILL, M.D.

GEORGE A. P., æt. 23, married, was admitted to the surgical ward of the Pennsylvania Hospital under the care of Dr. William Hunt, May 4, 1880, for a self-inflicted gunshot wound.

The conical ball, which weighed about six drachms, penetrated his clothing and

struck a pack of playing-cards which was in the pocket of his waistcoat, tearing them into fragments, thence, being deflected downward and to the right, passed between the waist-band of his drawers and the skin, following the contour of his person until it reached the right gluteal region, where, being spent, it dropped down his leg and was found in his boot. Upon the left epigastrium was a deep powder-burn, which could barely be covered by the hand,—the integument having been destroyed, and the grains of powder blown deeply in. From this burn there extended to the right, and somewhat downward, a bright-red track or score across the abdomen and around the right side as far as the right gluteal region, corresponding to the course taken by the missile along the waist-band of his clothing.

The integument in the track of the ball sloughed, and a superficial linear ulcer resulted. The ulceration caused by the powder-burn remained obstinately open for some time, this being due to the very ragged nature of the wound, and to the irritative action of the grains of unburnt powder, which had been blown deeply into the tissues. The patient was discharged cured about five weeks after receipt of injury.

Upon examining the bullet it was found to have lost to a considerable degree its conical shape, the point being crushed down and rounded off, so great was the resistance offered by the pack of cards. After penetrating these, its momentum must have been very much reduced, else it would have done more than wander peacefully around his waist-band and drop into his shoe.

TRANSLATIONS.

Simple Hepatic Engorgement—Its Treatment by the Douche and by Massage.—Dr. Durand-Fardel (*Bull. Gén. de Thérap.*, vol. c., 1881, p. 241) calls attention to this method as a valuable adjuvant to the ordinary treatment. Simple engorgement or chronic hyperæmia of the liver is characterized by general or partial enlargement of this organ,—usually enlargement of the left lobe. There are no tumors or inequalities of surface, nor is there excessive hardness. Pain, whether spontaneous or aroused by pressure, is observed only at intervals, and is sometimes entirely wanting. It never offers the character or the fixity of cancerous pain. Icterus may be wanting or very faint. The cachectic tendency of organic lesions is likewise wanting, and the duration itself of the alteration furnishes a diagnostic point regarding this last feature, as in the case of sclerosis. Neither the glycogenic nor the hæmatosic functions attributed to the liver are affected. The circulation is generally not interfered with. Anasarca and ascites are absent. Finally, this engorgement is susceptible of resolution even after a long duration, and its persistence will lead to the belief that it has been replaced by hypertrophy or induration.

Vichy, of which Dr. Durand-Fardel is director, proves very successful in the cure of these affections of the liver, and numbers of cases come under his observation.

Of one hundred and thirty-three cases noted by Dr. Durand-Fardel, forty-three were said to have followed upon acute attacks, usually described as resembling hepatic colic or perihepatitis. Seventy-two developed gradually, and eighteen in an almost latent manner, their advent having been masked by dyspeptic symptoms. Whatever the method of onset, however, this variety of engorgement presents, when fully developed, nearly the same symptoms in every case. Simple engorgement of the liver often appears to be connected with some embarrassment of the circulation, and, indeed, not unfrequently, with cardiac disease.

The time-honored treatment at Vichy has comprised simply baths, with the internal employment of the waters. For some time past, however, Dr. Durand-Fardel has added to this the employment of douches directed against the hepatic region. He does not employ these except in the absence of painful symptoms, either spontaneous or aroused by pressure. The existence of intercostal neuralgia is likewise a contra-indication to the employment of the douche. The douche used by Dr. Durand-Fardel is in the form of a rose, throwing a fine spray against the part. The patient does not begin to use the douche for a week after arriving at the springs, and at first it is employed only on alternate days. It is suspended at once if any uncomfortable feeling is produced. These douches, which

are called resolvative, are employed just before the bath, and at the same temperature,—34° Centig. Their duration is five to ten minutes, while the bath following lasts half an hour to an hour. These douches are well supported, and their employment is followed by a general feeling of buoyancy and of relief in the hepatic region.

In most cases this treatment is very satisfactory, the general condition of the patient improving and the various symptoms of dyspepsia disappearing. The liver does not, however, in many cases, diminish much in size during the month or so while the patient is under treatment, but the diminution and general improvement go on after the patient leaves. The entire treatment of these chronic cases lasts over several years. What is gained by each visit is retained, and in the immense majority of cases the patient ultimately recovers. The waters should be taken in small doses between-times, and baths of Vichy-salt should also be employed.

While the douche as above described is itself a sort of massage, yet there are a certain number of cases where the ordinary methods of massage may be supplemented to the use of the douche. In using massage here, the abdomen is first kneaded all together,—that is, the general intestinal mass; then the hand is passed by gentle friction over the hepatic region, the skin which covers the engorgement is squeezed first, and then the deeper parts are pressed more and more deeply, with alternate movements of gentle tapping with the palm or surface of the fingers. Finally, the liver itself is kneaded, and its lower edge raised by seizing it in the hand. It is hardly necessary to say that these manipulations should be performed with the utmost gentleness and care, and that they should be gradually accomplished, and not completed at the first sitting. The operation is generally very agreeable to the patient, and is followed by a buoyant feeling. It should last five to twenty minutes (with brief intervals in the latter cases), and should not be repeated more than once in two days.

The contra-indications for massage are the same as those for the douche, only intercostal neuralgia is excepted, as its existence does not interfere with massage. Dr. Durand-Fardel considers the *modus operandi* to be purely mechanical. The liver is emptied in part of its fluids as water is squeezed out of a sponge. In addition, massage acts favorably on the circulation, and thus hastens absorption.

Etiology of Amyloid Kidney.—E. Wagner (*Deutsches Archiv für Klin. Med.*, Bd. xxviii. p. 417) had been collecting facts bearing on this subject during many years, when he met with Henning's dissertation (Kiel, 1880) on the statistics and etiology of amyloid infiltration. Had he known Henning was at work, says Wagner, quaintly, he would have spared himself the troublesome task. However, it is of interest that the results of both observers tally.

Wagner has made autopsies of two hundred and sixty-five cases where amyloid kidney was found. Of these, one hundred and thirty-six cases were phthisical. Chronic pulmonary phthisis occurred in one hundred and thirty-three of these cases, with concomitant tuberculous ulceration of the intestine in ninety-eight cases. Two cases showed chronic ulcerative tuberculosis of the intestine without lung-complication, and one case showed caseous degeneration of the mesenteric glands without intestinal or pulmonary disease. In one case there was slight pulmonary and no intestinal complication, but well-marked tuberculosis at the root of the tongue and in the larynx.

In seven cases there was some chronic etiological (though probably subordinately so) osseous affection in addition to the phthisis.

The age of the patient was in eighty-seven cases under thirty years,—usually between twenty and thirty. Forty-nine cases were over thirty years of age (ten of these were fifty and over). The oldest, a woman of seventy-four, died of senile gangrene of the foot.

In one hundred and twenty-five cases lardaceous spleen, and in eighty-one cases lardaceous liver, were present. Wagner thinks the proportion would have been higher if these organs had always been examined microscopically. The lardaceous spleen was not infrequently considerably enlarged, while the liver was, as a general thing, only very slightly so, and therefore could not aid in the diagnosis during life.

General dropsy was present in twenty-seven cases; œdema of the lower part of the body in seventeen.

The final cause of death was as follows.

In six cases, suppurative peritonitis (most likely the result of intestinal ulceration). In one case there was simultaneous suppurative peritonitis, pleuritis, and meningitis; in five cases, pneumothorax (once of two years' duration); of tubercular meningitis, hæmoptysis, pneumonia, and laryngeal croup, one case each.

The heart was usually normal, apart from general diminution in size and from not unusual right-sided eccentric hypertrophy. In a number of cases surprising diminution, etc., or brown atrophy was noted. In one case there was hypertrophy of the left ventricle (without macroscopic diminution in the size of the kidney). In one case there was dilatation without hypertrophy.

Disease of the bones was observed in connection with amyloid kidney fifty-six times. The affection was always chronic, but was less varied in character than in locality. (Syphilis of the bone is considered later.) The suppuration, or rather the ulceration, of the bone was present in most cases at the time of death. In other cases the disease was more or less healed, showing, however, the marks of previous communication with the outer surface. In a few cases suppuration had apparently not taken place. Wagner goes on to give the various bones affected, the age of the patients, and the concomitant disorders, as before. He then alludes to the occurrence of amyloid kidney in syphilis, referring to a previous article on this subject published in the same journal (Bd. xxviii. p. 109). He saw thirty-six cases in all, eighteen of which showed concurrent ulcerative lesions of the skin and bones; nine cases showed severe ulceration of the skin and mucous membranes, and there were nine where other diseases besides syphilis existed which could be considered of etiological importance. In thirty cases there was lardaceous disease of the spleen, and in sixteen the same affection of the liver. Fourteen showed general dropsy; three, œdema of the lower extremities. In three cases there was granular lardaceous kidney with hypertrophy of the left ventricle. Two patients died of uræmia: both of these showed the usual amyloid kidney.

In thirty-seven cases the amyloid kidney could be attributed to or was connected with unusual causative affections. Sacculated bronchiectases, chronic suppuration or ulceration of the skin, severe variola, chronic suppuration of the mucous membrane, chronic empyema, chronic pyelitis or pyelocystitis, chronic parametritis with fistula of the bladder, primary psoas abscess, and ulcerating cancer, were the causes which in one or several of these cases existed. Finally, seven cases of amyloid kidney were observed where absolutely no causative disease of other parts of the body could be found to exist.

A Case of Anæsthesia of the Shoulder and Forearm, of Reflex Origin and consecutive to a Wound of the Axillary Region, cured by Successive Application of Blisters in the Neighborhood of the Cicatrix.—Dr. Malecot writes to the *Bulletin Gén. de Thérap.* (vol. c., 1881, p. 259), describing the case of a woman who received, on the 1st of December, a knife-wound in the axilla, three finger-breadths below the outer end of the clavicle, two centimetres in length, and of an undetermined depth. It was evident that no large vessel had been wounded, and exploration showed that there was absolute anæsthesia of peculiar distribution, not corresponding to the distribution of any nerve. It might be stated roughly to include the entire posterior scapular region, the subclavicular region a finger-breadth below the breast, and the entire axillary region. The arm and the upper third of the forearm were likewise anæsthetic at all points, the anæsthetic area terminating abruptly at a certain point, the wrist and hand being unaffected. Motion was unaffected. The wound healed nicely, and by the end of December was entirely cicatrized. The anæsthesia, however, continued, and the patient complained of numbness and cold with occasional severe pain in the region of the shoulder. After the wound had been cicatrized some three days, paresis began to appear in the extensors of the forearm. The fingers could not be straightened from the palm, nor the hand from the wrist, except incompletely. The pain in the shoulder continued. Dr. Dumontpallier, who was in charge of the case, considered the trouble to be reflex in character, and, with a view to peripheral stimulation, ordered, on February 2, a blister of ten square centimetres (about three square inches) applied directly over the cicatrix. Other blisters were subsequently placed on the neighboring surface, and the normal sensibility slowly but steadily returned, the patient being discharged cured at the end of a month.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, JULY 16, 1881.

EDITORIAL.

MEDICAL SOCIETIES.

THE recent centennial celebration of the Massachusetts Medical Society was the occasion of an oration by J. Collins Warren, upon the organization and nature of the work of medical societies, which has since been published as a handsome and very interesting pamphlet, that should be read, and upon which we offer a few running comments.

The contrast between our American Medical Association and that of Great Britain is a very strong one. In England most of the great doctors of the nation are at the annual gathering, but in this country, with few exceptions, the foremost medical men do not attend the annual meeting. The reasons of this seeming lack of spirit are, to our thinking, very obvious: they are the size of the country and the absence of centralization.

It does not pay Dr. Jones to go to New Orleans at an expense of some hundreds of dollars and at a loss of much time, because his consultation-business is not to be thereby benefited; whilst it does pay the rising London consultant to spend his pound or two to go to Leeds, Edinburgh, or Glasgow, because neither of these places is outside the limits of his reach as a consultant. That this difficulty can be overcome by any peculiar reorganization of the American Medical Association may be possible, but seems to us doubtful. A similar obstacle lies in the way of a successful national journal. New Orleans feels medically little if any more in common with Boston than with London or Paris; whilst Birmingham bows itself to the British metropolis.

The plan, favored by Dr. Warren, of establishing a national council, a sort of medical senate, the members of which are to be elected for a term of years by State councils, whose members in turn shall be selected from Congressional districts, may possibly be a feasible one, but it will be difficult to persuade the present American Medical Association to perform the *auto-da-fé* necessary before its ashes can give birth to the new phœnix. We heartily agree with Dr. Warren in thinking that some radical change in the organization of the Association must precede the establishment of a successful national medical journal.

Whether the democratic constitution and habits of our country are consistent with legislative regulation of the profession or not is a problem not yet solved, but for whose solution material is now beginning to accumulate. By the law of 1877 in Alabama, the State and county boards of censors of the Association were constituted boards of examiners, by whom all persons intending to practise medicine must be examined, partly orally, partly by writing. The law is apparently being actively carried out. In North Carolina the State Society appoints a board of medical examiners. Any one may practise in the State, but no person, unless he has been licensed by this board, can collect fees at law. It is stated by the Secretary that the law is working very well, and that the people themselves are beginning to enforce its intention, no new man who does not have the license of the board having any chance for practice. In Texas, examining boards are appointed by judges of the district court. In Illinois, the State Board of Health has charge of the licensing of physicians: it does not examine, but gives the right to practise upon presentation of a proper diploma.

ALEXIS ST. MARTIN, the Canadian whose gastric fistula, with the experiments on digestion which it afforded, had made himself and Dr. Beaumont famous, is dead.

TOBACCO-CULTURE IN THE UNITED STATES.

AS conservators of the public health, as citizens interested in the growth of the country, and as men with bodily wants, most of American doctors are sufficiently interested in the subject of tobacco-growth to glance at the results of the last census. It is shown that the increase of the production for the whole country has been about eighty per cent, and further details are added from a recent census bulletin:

"Fifteen States produce now, as in 1870, more than ninety-nine per cent. of the tobacco of the United States, though it is reported in twenty-two other States and six Territories. Of these fifteen, only Missouri, Illinois, Indiana, and Massachusetts produce less than in 1870. Kentucky occupies the first position, producing thirty six per cent. of the total product of the country. Virginia holds the second place; Pennsylvania has advanced from the twelfth to the third.

The average yield per acre is 731 pounds. The variation in rate of yield, from 1599 in Massachusetts to 471 in North Carolina, is due in differing degree to the use or neglect of fertilizers, the habit of growth of different varieties, and the vicissitudes of the seasons. In Massachusetts, Connecticut, New York, Pennsylvania, and Wisconsin, the seed-leaf varieties are mainly grown and high fertilization practised, always resulting in comparatively heavy crops. In Ohio the yield is above the average, the Ohio seed-leaf being extensively cultivated in the Miami Valley, while the Burley, a vigorous grower of a less productive class, is almost exclusive in its prominence in the Ohio River counties. Kentucky, producing many grades of cutting and shipping tobaccos, upon an unexhausted soil of great original fertility, makes an average yield. In Maryland, Virginia, and West Virginia the yield is less than the general average. The low yield in North Carolina is a necessity of the production of the fashionable yellow "bright" grade used for plug-wrappers, grown on a poor soil, with low fertilization sufficient to stimulate early growth, but not enough to prevent early maturing."

IT gives us much pleasure to welcome the second volume of the Index Catalogue of the Surgeon-General's Office. The characteristics of it are precisely those of the first volume. It is a very handsome volume, and, simply as a specimen of accurate proof-reading, a remarkable production. The magnitude of the labor it represents is appalling.

PROF. MAURICE RAYNAUD, the giver of the French address at the coming International Medical Congress, has chosen for his subject "Le scepticisme en médecine au temps passé et au temps présent."

LEADING ARTICLES.

SYMPTOMATOLOGY OF TENDON REFLEX.*

IN a previous article we have indicated the course of the nervous currents concerned in the production of tendon reflex. The integrity of these lines of conduction is of course necessary to the proper occurrence of the symptom. Every obstacle to the nervous current either gives rise to an exaggeration of the tendon reflex, if its effect is irritative, or to the abolition of the reflex, if the lesion is a destructive one. We are now prepared to examine these two conditions, and to review the diverse medullary affections in which tendon reflex is exaggerated or abolished.

Cases in which tendon reflex is exaggerated.—Sclérose en plaques is the affection in which exaggerated tendon reflex was first observed by Vulpian and Charcot. In this disease, percussion of the rotular tendon gives rise to a more rapid and decided elevation of the point of the foot than is observed in the normal condition, while at the same time the cutaneous reflex remains unaffected. Exaggeration of the tendon reflex is a most important symptom in *sclérose en plaques*, because very often it is the only positive symptom observable in atypical cases. Sometimes it happens in the course of the disease that the reflex, at first exaggerated, disappears, and that exaggerated in some muscles it may be abolished in others. This is because a patch of sclerosis has invaded the posterior root of nerves corresponding to that region, and has thus broken the continuity of the diastaltic arc.

In the *spasmodic tabes dorsalis* of Charcot, the *spasmodic paralysis* of Erb, exaggeration of the tendon reflex is also observed. In fact, this symptom is here found to the most marked degree; for here, without any appreciable cause, a certain trepidation supervenes which may be confined to the extremities or may extend to all the limbs, or even to the entire body. Trepidation may even be obtained from the knee, so exaggerated is the patellar reflex. Percussion of the tendon of the biceps, triceps, radialis, supinator longus, and flexor of the fingers may give rise to

---

* See Medical Times, No. 355, July 2.

the reflex; and Erb has even in some cases provoked the appearance of this symptom in the hand. Charcot calls the affection the type of spasmodic diseases. In some cases, motor feebleness coexists with tendon reflex, so that movement becomes impossible, and this forms the condition known as spasmodic pseudo-paralysis. At one period of the disease the exaggerated condition of contraction may prevent the excitation of tendon reflex. As to the cutaneous reflex, it is sometimes increased and at other times diminished.

Sometimes a lateral sclerosis is added to the lesion of the anterior cornua of the cord, and we have lateral amyotrophic sclerosis. The symptoms of lateral sclerosis are associated with those of invading muscular atrophy. These symptoms are observed chiefly in the upper limbs, while the lower extremities only present rigidity, contraction, and exaggeration of the tendon phenomena. There is only irritative functional derangement of the ganglionic elements of the cord in these cases, and no destructive lesion.

Post-hemiplegic contraction from secondary degeneration of the antero-lateral filaments belongs in the same category. Charcot and Brissaud have recently shown that the morbid changes in these cases are preceded first by exaggerated tendon reflex, and then, when they have become more destructive in character, by abolition of tendon reflex, the reflex symptom in each case indicating beforehand what may be expected. Brissaud has demonstrated a curious fact in investigating the rapidity of conduction of the tendon reflex. He has shown that this is shorter on the *well side* of a hemiplegic than it would be in health, and has thus shown that the well side is not in reality well. This observation agrees with that of Dejerine, who in five cases observed reflex trembling of the healthy member as intense as that of the paralyzed limb. A curious fact is observed in hemiplegic patients,—namely, sensitiveness to percussion of the patellar tendon. In the healthy subject this may be struck a number of times, but in cases of hemiplegia with contraction the blow of the mallet gives rise to a painful sensation, of a transitory character, it is true, but which is felt by some patients as an object or body mounting the dorsal vertebræ, while others feel it as a sensation of contraction in the abdomen. It is, in fact, a true aura, of which the localization varies in different individuals. These sensations, Brissaud says, are observed only when the tendon of the paralyzed side is percussed.

Now, having hastily sketched the various symptoms connected with tendon reflex in hemiplegia with contraction, let us turn to the period at which these appear. According to Brissaud, in one case observed at the Salpêtrière, the trepidation showed itself eight days after the attack, while it was only twelve days later, or nearly three weeks after the attack, that contraction began to appear. The exaggeration of the knee reflex is therefore the initial symptom in these cases.

It is not only in cases of hemorrhage or of cerebral softening that exaggeration of tendon reflex is of importance, but in all diseases of cerebral origin where it is met with the diagnosis of secondary degeneration of the antero-lateral filaments may be decided upon. In one of Westphal's cases, a patient who had shown symptoms of exaggerated tendon reflex during life showed at the autopsy a myxosarcoma of the right hemisphere, with medullary degeneration; and Petitclerc gives in his thesis the case of a patient with chronic hydrocephalus who had exaggeration of the tendon reflex. Exaltation of this symptom has also been noted in hypertrophic cervical pachymeningitis.

In the same order of facts must be placed *hysterical contraction* with ovarian hyperæsthesia and hemianæsthesia. Here, also, tendon reflex is easily and markedly aroused. The symptom may be observed before the patient shows signs of contraction, and it may announce the near advent of the latter. It is to be noted that in these cases the cutaneous reflexes are entirely abolished, and may not be aroused by the strongest provocation,—facts which go to support Charcot's view of the independence of the diastaltic arc of the cutaneous reflex and that of the tendon reflex. The physiological explanation of these phenomena is difficult to give; though it seems possible that they are due to an irritation of the motor cells of the anterior cornua, analogous to the irritation produced by strychnia, but more durable than this.

The relations between hypnotism and tendon reflex have recently been made the subject of study by Dr. Paul Richer. The different nervous conditions to which the

state of hypnotism may give rise are of two kinds, as regards their connection with tendon reflex. In the first condition, that of induced hysterical lethargy, accompanied by neuro-muscular hyperexcitability, tendon reflex is markedly exaggerated, while in the second, that of induced hysterical catalepsy, tendon reflex is completely abolished.

In *chorea*, *eclampsia*, and *epilepsy*, the tendon reflex phenomena have not as yet been studied, some observers having reported cases where the reflex was exaggerated, while others, on the contrary, assert its abolition. Petitclerc, studying under Straus, has observed exaggeration of the tendon reflex in choreic patients.

In *paralysis agitans* the tendon reflex is not exaggerated.

While the clinical importance of exaggeration of the knee phenomena and clonus of the foot cannot be overrated, a scarcely less important place must be given to the disappearance of these reflexes as indicating an interruption of the diastaltic arc.

Westphal was the first, in 1878, to draw attention to the disappearance of the patellar reflex in *locomotor ataxia;* and this symptom, confirmed by Erb, has taken an important place in the clinical study of this disease, because it may be observed at a period so early that no other symptoms shall have manifested themselves. If a patient presenting the symptoms of amaurosis or lancinating pains is found in addition to show disappearance of the tendon reflex, a diagnosis of locomotor ataxia may almost certainly be made. Is this symptom constant? While Erb noted its absence in but one case out of fifty-five, and Berger in two cases out of nineteen, McLane Hamilton observed it in only one-half the cases coming under his notice. Dr. Ollive suggests that this may have occurred in Hamilton's cases because the lesions of the posterior columns were accompanied by lesions of the lateral columns in addition.

Tschiriew has established the fact that disappearance of the knee phenomenon in *tabes dorsalis* is due to the destruction of the commissural fibres of the external portions of the posterior columns, whence the impossibility that the excitation derived from these can reach the motor cells.

In *infantile paralysis* and *progressive muscular atrophy*, affections where the anterior cornua of the cord are involved, we would expect to find diminution followed by abolition of the tendon reflex; and in fact this condition is found to be present. It is possible that in the earlier stages of muscular atrophy the tendon reflex may still be preserved; but later, when the lumbar cord becomes affected, the reflex disappears.

Our present knowledge of the pathological anatomy of *diphtherial paralysis*, thanks to Dejerine, is such as to enable us to range it with the preceding affections. Westphal, Rumpf, Schultz, and Berger have shown that while the tendon reflex is abolished in this affection, yet the transient character of the paralysis is shown by the fact that the reflex is restored later; and indeed it might be said that the return of the patellar reflex proves the simultaneous recovery in the nervous elements.

In acute and chronic *myelitis* tendon reflex is very variable, according to the seat of the lesions, and permits of their evolution being followed. In certain cases of *spinal meningitis* the tendon reflex also furnishes indications. For if its exaltation does not indicate an invasion of the lateral columns, it at least points to a certain degree of irritation. In *Pott's disease* tendon reflex is of great importance, and it is found to appear and disappear from time to time. *Compression of the cord* is also followed by exaltation of the tendon reflex.

Thus far we have taken into consideration only the tendon reflex phenomena in connection with affections of the spinal cord; but before we conclude we may say something regarding these phenomena as observed in general affections. Strumpel has observed that the exaggeration of tendon reflex is not a symptom peculiar to affections of the nervous centres, but one which may be seen equally in certain cases of phthisis, in the course of typhoid fever, and in poisoning by strychnia and by atropia. Straus has also made some investigations which are recorded in the thesis of Petitclerc. In phthisis he finds the tendon reflex quite normal; so that it is possible Strumpel's case may have had some lesion of the cord or its envelopes. In typhoid fever the reflex is rather diminished than exaggerated, and in a case of hemorrhagic variola with paraplegia it was found to be completely abolished. The exact causes of the abolition or exaggeration of tendon reflex in these cases is not known; and indeed there is much to be done before any conclusions can be clearly formulated

which will cover the ground satisfactorily. Enough has been said, however, to show the daily growing importance of a study of these phenomena of tendon reflex, which in all probability are destined to play a prominent part in the practical study of nervous diseases.

CORRESPONDENCE.

LONDON LETTER.

THE dependence of health upon the perfection of our sanitary and hygienic arrangements is now generally recognized. The profession has done its duty nobly to the public in the matter of the prevention of disease, and yet its unselfish attitude has gained for it little gratitude. On the other hand, certain dishonest contractors are determined to push the interests of the profession in spite of its efforts to prevent disease. When a man buys a house or takes it upon lease, his first inquiry is, "How about the drains?" He is volubly assured that all is perfection; no suspicion need haunt his mind; he may be perfectly easy upon that head. He brings his family into the new residence, and soon first one sickens and then another. At last it becomes absolutely necessary to inspect the drains, and then the mystery is solved. At very considerable expense the drains are put into fair order, and the house becomes habitable; but it is hard upon the tenant to have to be at all this expense of doctors' bills and drain-repairing because somebody is a thief or a liar,—probably both. No doubt the owner wished to avoid any expense he could; the contractors had a human desire to make as much profit as was possible; and between the two the tenant is heavily mulcted, and some doctor gets fees he in no way designed to get, and who is in no way a party to the fraudulent transaction. When the laws which regulate man's duty to man become inefficient, and the moral laws are inoperative or insufficient to inspire conduct, then something must be done. Society does not exist for the benefit of any particular class, nor do we now admit that the many are here merely to minister to the few. It was, then, with the utmost satisfaction that I read that the Brooklyn plumbers are up in arms against a new legislative enactment to have official supervision of their work. It is quite clear that they are apprehensive; else why their perturbation? The progress of this new scheme and its practical results will be watched with the keenest interest by the long-suffering householders of this effete old country. Here we have borne the burden of plumbers till our withers are wrung. Old houses have much to recommend them; but the modern plumber does his best to maim the good work of his predecessors. Pipes are made so as to leak at the earliest possible date. The water-pipes are laid alongside or under the soil-pipes, so as to secure the introduction of sewage-matter into the drinking-water before very long. Whether the plumber thinks the medical man a confederate or not does not appear, nor is it possible, because the doctor has just the same difficulties to contend with in a new residence which meet others. The godless plumber goes on his way. He leaves a brazier burning with a light heart unburdened by care; and next morning we read that a church has been burned down or one of our national buildings, some old castle or hall, is no more. The plumber is at fault again. We have become so accustomed to his iniquities that we scarcely feel indignation. Then pipes are placed where it will cause infinite trouble to reach them when repairs are required; or the cistern goes wrong, and half a ceiling is ruined beyond repair, while the house is rendered damp and unwholesome for a long time afterwards. The plumber goes on his way rejoicing. He has made a little more work for another artisan, and has so fulfilled his duty towards his neighbor. Yes, but which neighbor? His fellow-workmen have been benefited, but it is at the expense of another neighbor. That is a matter of no moment whatever. He is only a professional man, or a clergyman, or "in the city." What does the plumber reck about that? The time is rapidly coming when the instinct of self-preservation will impel society at large to insist upon legislative measures to restrain such practices. Money is spent lavishly upon schemes to supply a fairly pure water, to dispose of the sewage in an innocuous manner; yet these schemes are all thwarted by the wiles of the builder and the plumber. As knowledge extends, so will the ability to detect these fraudulent arrangements obtain; but there is much left to be desired in the sanitation of our dwellings.

The favorite study of most of the enthusiastic workers in the profession is, for surgeons, Listerism; for physicians, nervous diseases. The two currents are carrying in their stream all, or nearly all, ardent workers. To put aside the psychoses for the present, and pursue the maladies of the sane, it may be said that the work of Duchenne de Boulogne is being extended, and the clinical observations of the French school join hands with the results of experimentation for which we owe so much to the Teuton workers Fritsch and Hitzig. The injuries of the nervous system have been fully described by Weir Mitchell, who occupies so honored a place in American medicine. Ferrier has, in this country, done immense service in grouping the information derived from various sources, and illustrating and advancing it by much

original work of his own, so as to throw the whole together in harmonious form. Hughlings Jackson has given a precision to clinical observation unknown before his time. Charcot has given nervous affections a prominence in France which without him they might not have attained. What would have been regarded as prodigies of diagnostic acumen almost incredible twenty years ago are now taken quite calmly, the perturbation due to novelty having passed away. Daily we are prepared to hear of a tumor being diagnosed and its locality so precisely ascertained that an enterprising surgeon has cut down upon it, dissected it out, and by dint of the most careful antiseptic precautions secured a happy convalescence,—the compressed portion of the cortex recovering its functions when relieved from the pressure. Nor would any such operation create great surprise: indeed, we are waiting rather impatiently for this to be done. There is certainly a wave of inquiry passing over us which is rapidly bringing with it practical results; and our knowledge of the diseases and disorders of the nervous system is extending to meet the accumulating demands upon it. No sooner does physiology make a step forward than practical medicine declares that this is the very precise and exact piece of information it was in want of to meet some newly-recognized condition, or some new emergency brings out a new nervous affection hitherto either unknown or unrecognized. The tread of advancing neurosal affections is audible enough: we hear it and its echo everywhere. We glance through a provincial newspaper and read that the magistrates have been greatly perplexed how to provide accommodation for the numerous insane, the demand for space being terribly on the increase. A new asylum to hold eight hundred inmates is absolutely necessary in a manufacturing county; a new wing is required in another county. Nervous affections among the sane are equally rife; and hospitals for diseases of the nervous system are springing up all over the land. It is not many years since, in the American Civil War, Da Costa observed "the irritable heart;" now it is quite a common phenomenon. The effects of excitement and nervous worry are impairing the assimilative powers, and indigestion stalks about,—a nineteenth-century monster. The chemist comes forward politely and proffers some vegetable diastase to help the little baby to digest the starch of its food; another blandly places before the dyspeptic a bottle of pepsin wine, and assures him that in it he will find a remedy for his troubles. The physiologist preaches the potency of the pancreatic secretion, and long ago (*i.e.*, in this quickly-moving age) Dr. Horace Dobell announced a pancreatic emulsion of fat for the consumptive. More recently, Dr. W. Roberts has held up before our gaze a bottle containing a bland but weirdly potent fluid,—the *liquor pancreaticus*,—some of which has only to be safely passed through the acid stomach under the guard of alkali, and, *presto*, the difficulties of digestion are overcome. Then followed peptonized foods of various kinds, as any one may read on the circular wrapped around each bottle of the magic fluid. The digestive act in the alimentary canal is rendered almost unnecessary in the economy. Just as this discovery dawns upon us, we are told that these peptones are a potential source of danger. Unless they are reconverted into proteids, they are toxic agents. The liver is a large gland which is also a filter. The products of gastro-intestinal digestion are elaborated therein for the albumen of the *liquor sanguinis*, or driven backward as waste into urea, or, when the metabolism is perverted, into uric acid. Certain parts of the surplusage are converted into bile for use in a lowlier form. At the same time we begin to note that mental states affect the liver; worry interferes with the later and higher part of the assimilative act. The liver requires a stimulant. Well, has not Professor Rutherford been engaged on that very subject? and a whole lot of hepatic stimulants have just been launched on the world. Each step forward in one direction is accompanied by a step onward in another. If neurosal affections are on the spread, we are on their track. Really, we must feel some respect for the human intellect, at least so far as the conflict with diseases is concerned, if in no other direction. The old Anglo-Saxon plan of rising to meet an emergency is once more to the front, and difficulties exist but to be met and overcome.

But to revert to the literature of diseases of the nervous system. There are the comparatively complete treatises of S. Wilks and Julius Althaus, the works of Ferrier as to localization of function in the brain and the localization of cerebral disease, with other less important but still valuable essays by Hughlings Jackson, Gowers, and others. But recently a large and ambitious treatise in two corpulent tomes has been put forth by a rising provincial physician, Dr. James Ross, of Manchester. Placed in a grand field for observation, Dr. Ross has availed himself of his opportunities, and this magnificent work is the outcome of his labors. To those already familiar with the systematic works of Hammond and of McLane Hamilton, this treatise will be specially acceptable. It is illustrated by numerous engravings, many copied from standard works, but more drawn from original sections, microscopic and other, made by the laborious author. Those who know Dr. Ross personally know how thorough and genuine is his work, and how complete his devotion to his task. An industrious, thoughtful Scot, he labors and toils away, comparatively regardless of the practical outcome of his labor, but devoted to his work. He com-

mences with an introduction on the structure and functions of the nervous system. In the chapter devoted to etiology he lays stress upon the unstable nervous system otherwise known as the "neurotic disposition." He regards ethyl alcohol as one of the most wide-spread of causes of disease of the nervous system. He is very precise about prefixing "ethyl" to alcohol. Further he writes, "Chemical poisons are being constantly generated in the system as the result of normal disintegrative processes; but under healthy conditions these are eliminated so rapidly by the excretory organs that they do not accumulate in sufficient quantity in the blood to injure the nervous tissues. When, however, the normal excretory processes are diminished or arrested by disease, or when an undue quantity of those poisons is generated, serious nervous disorder results. It is not, therefore, surprising to find that the diseases of the lungs, of the kidneys, and of the other excretory organs are frequently accompanied by grave nervous symptoms." The "trophic neuroses" are considered in a chapter of their own. The neuralgiæ are well described, the text being illustrated by good cuts. The second volume is a rather ponderous tome, evidently having grown under the author's hand till it has quite outgrown its older brother. It deals with the cerebro-spinal system, the diseases of the spinal cord and medulla being considered first. The arrangement is instructive and very interesting, and will repay careful consideration. Finally, the diseases of the encephalon are given, and the diseases of the encephalo-spinal system. Here the reader will find, if not all he would wish to know,—for, indeed, it would be a marvel of a book if it could do that,—very much that he wishes to know about a very interesting class of diseases, marshalled for him by a man who is master of his subject. The phraseology is adapted to the time, and represents the latest information on the subject treated of,—localized and diffused lesions. The affections of the different areas, lesions of the vascular areas supplied by certain arteries, diffused diseases of the cerebral hemispheres, encephalitis, diseases of the membranes,—all are given in serried array and order; lastly, paralysis, chorea, tetanus, hysteria, epilepsy, and toxic affections. If the reader is disposed to enlighten himself upon the diseases of the nervous system, and especially their pathology,—about which so much has been done of late,—he will have in this work a mine of wealth to explore. He will find Dr. Ross holding strong views about the large cells representing inherited matters, and large muscles, and the smaller cells representing individual matters; these last being the latest in development and the first to go in disease. He will find many lesions described into their minutiæ with all that the most modern research, physiological and pathological, can tell, arranged and digested for him in lucid form; plates of the changes found in hydrophobia and tetanus, with the leucocytes which are developed, *et hoc genus omne*. We have had few medical works of interest out this season, and Dr. Ross's is by far the most ambitious and most important issued so far, or likely to be. It is of interest, too, as showing that the metropolis does not contain either all the talent or all the energy, and that in the provinces there are quite as good men in every way. William Roberts and James Ross in Manchester, Clifford Allbutt in Leeds, Mitchell Banks and Braidwood in Liverpool, Balthazar Foster in Birmingham, Long Fox in Bristol, Phillipson in Newcastle, and others, as physicians, are equal to the leaders in London in the essentials of practice; while as to surgeons the list of provincial men is a formidable one. The peculiarities of each district are well worth the studying, and in the great cotton district Dr. Ross has a grand field for study; and those who read his book will probably rise from its perusal with the conviction that he is the right man in the right place. As disease manifests itself variously in different areas, it is well to have a photograph of it taken in each area: from a series of these photographs a typical representation of it may be constructed which will be at once representative and correct.

J. Milner Fothergill.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting of the Society was held at the Hall of the College of Physicians, Philadelphia, April 27, 1881, Dr. Albert H. Smith, President, in the chair. Papers were read by Dr. Roberts Bartholow on "The Therapeutics of Alcohol used Internally and Externally;" Dr. Henry Leffmann, on "The Medical Relations of the Commercial Adulterations of Wines and Liquors;" and Dr. H. C. Wood, "Is Alcohol a Food?—When Should Malt Liquors be Preferred to Wines and Spirits in the Treatment of Disease?"

DISCUSSION UPON ALCOHOL.

Dr. George Hamilton regarded the nourishment of the patient as the main point in the treatment of exhausting diseases: stimulants might aid nutrition, but cannot take the place of food. In declining years of life a moderate amount of alcohol may be of service, but in youth it should be used with the utmost caution. The recommendation of Todd had been too closely followed, and he could now see signs of a reaction against indiscriminate

stimulation. Typhoid fever is most likely to occur at from sixteen to twenty-one years of age, which also is a very fatal period. The mucous membrane of the alimentary tract being at this age unaccustomed to alcohol, the greatest caution should be observed in giving large amounts of stimulants. It is usually recommended to be given early in the disease, which he regarded as wrong. Even in phthisis it should be used with care. He believed that the physician is often unjustly blamed for having recommended stimulants to persons who form the habit of drinking to excess; and he cited a case where a man was said to have died a drunkard because a certain doctor had prescribed brandy for him. It was subsequently learned that the man was a drunkard before he ever saw the doctor.

Dr. H. C. Wood said that he was reminded that he had forgotten to refer to the use of alcohol as an antiseptic. In simple alcohol we have an antiseptic agent which is capable of banishing Listerism from surgery, if properly used. He would simply dress the stump with a cloth kept constantly wet with alcohol. No germs could possibly enter the wound, and the remedy is much safer than carbolic acid. He could not admit, however, that alcohol exerts this same antiseptic effect after entering the blood: the protoplasm of the blood-cells is just as delicate as the protoplasm of the micrococci. Such treatment would be like the proposal to kill trichinæ in the muscles by giving the patient picric acid: before it poisons the parasite, the patient becomes translated.

He agreed with the last speaker in condemning the abuse of alcohol as an antipyretic. Alcohol should not be used in a routine manner in fevers, but should be held in reserve. It is of use in low fevers in other ways than as an antipyretic. From a number of calorimetric observations upon animals he had concluded that alcohol had no influence upon tissue-change or the production of animal heat, but does exert an influence upon the throwing out of heat from the blood. The temperature falls because more heat is dissipated, for the same reason that it falls after section of the spinal cord. Vaso-motor palsy leads to a decline in the temperature, whether caused by injury or by alcohol. It is very plain that if alcohol is to be given to produce reduction of heat in this way it will have to be given in large doses,—large enough to produce vaso-motor paralysis and depression, which we do not want caused in low fevers, and therefore cannot usually give it to reduce the heat to the normal temperature. As regards the quantity required he would not lay down any absolute rule. He referred to a case in which a man, after a rattlesnake-bite, took about two pints of whisky with only good result: an amount which in health would have depressed the heart only elevated its power under these circumstances. It is so in low fevers. Eight or ten ounces per diem in a low fever may produce no more effect than two or three ounces in health. A young lady suffering with typhoid fever under his care had a pulse of 140. He increased the stimulant until she was taking one ounce of whisky every three hours; but finding it impossible to keep it down below this point, as it was at the rate of 160 at the time of his visit one night, he increased the stimulant to two ounces every two hours. The next morning it was down to 120. It seems, in some cases of low fever, that an amount of alcohol, which could produce fatal depression in health, may only act as a vital stimulant.

Dr. Addinell Hewson saw something inconsistent in the last speaker's remarks. He had spoken of the effects of alcohol in retarding cell-growth when referring to its antiseptic effect; he had also mentioned an effect upon the blood-cells and in retarding the movements of the white corpuscle. As all tissue-change is dependent upon cell-growth, the speaker did not see how alcohol could influence the cell-movements without at the same time effecting tissue-change. This is the teaching of experience; and it therefore happens that alcohol often impairs nutrition rather than benefits it. The effect of alcohol upon the gastric juice is to precipitate the pepsin. To these facts may be attributed the injurious effects of alcohol in some depressing diseases.

Dr. C. B. Nancrede said that the alcohol-dressing of wounds was an old treatment. He thought that experiments made many years ago by Onimus, of Montpellier, upon animals demonstrated that it was not necessary to import micrococci in order to account for suppuration, showing, in fact, that the circumstances favoring suppuration and those developing micrococci are identical. He thought that there was danger of these experiments being overlooked. Fluids swarming with bacteria, which produced active effects upon the organism, were treated with bromine, chromic acid, and acetic acid, which were found to destroy the power of the septic influence of the fluids, but not the number or activity of the vibrios.

Dr. Toboldt said that he had seen bacteria flourishing in a sixty-per-cent. solution of alcohol, where they remained for more than a year without obvious change.

Dr. Hamilton noticed the diversity of practice. Some physicians say that they cannot get along without alcohol in the treatment of typhus and typhoid fevers, and others, on the contrary, never use it at all. If the same results always followed the alcohol treatment, its use would be more general.

Dr. J. T. Eskridge said that no precise rule could be laid down as regards the amount to be used. In one case he had given thirty-six ounces of brandy daily for several days,

with successful result. It was in the fourth week of a relapse of typhoid fever. The patient did not take much alcohol in the first attack, but in the relapse the temperature reached 105°, the pulse 160. Brandy was increased to one and a half ounces every hour, and continued for about six days. The patient finally recovered. As the pulse came down to 110 and the vital forces were restored, the stimulant was gradually reduced.

The speaker also referred to the value of stimulants in atonic dyspepsia, given directly after eating.

Dr. O'Hara had not seen adduced any satisfactory evidence that alcohol is a food. It is not used to nourish young children, nor to build up the strength of prize-fighters when in training. He agreed with the lecturer as to its value in low fevers, where it does seem to supply force to the patient. He regarded the whole question of its food-value, however, as still *sub judice*.

Dr. Bartholow said that he had no doubt whatever that the position taken by the writers that alcohol is in a very limited sense a food is correct, and one supported by the authorities of our time. Of this there can be absolutely no doubt: a substance undergoing oxidation in the organism is in the position of other hydro-carbons in the food. Alcohol is very valuable as a food, for it spreads out over the whole surface of the lungs, where it yields its force very promptly, as it is very readily oxidized.

In regard to its antiseptic action, he could speak of its good effects in preventing local putrefaction. For eight years he had served as military surgeon, and had had charge of several large military hospitals: he therefore spoke of what he had seen when he says that it is entitled, in his opinion, to the place scarcely inferior to carbolic acid. In referring to what had been said in regard to the septic character of fluids independent of minute organisms, he said that it is true that there is a substance different from these bodies which can produce injurious effects; but the speaker had evidently not seen the report of Burdon Sanderson's experiments to the Privy Council, from which the conclusion to be drawn is that minute organisms play a very important part in the production of sepsis, but they are not septic themselves. It is not the minute organisms, but their action, that concerns us, while it is seen that their discussion is a very important subject, as it concerns the development of poisons connected with their presence.

Dr. W. R. D. Blackwood said that from an extended experience as an army surgeon and in private practice, he could endorse the alcohol treatment of wounds. He had not seen better results from Listerism. He had at the present time two stumps under treatment, which had had nothing on them but alcohol. He was perfectly satisfied with the dressing.

Dr. W. H. Parish said that brandy is a very valuable remedy in cholera infantum; cases are lost from not resorting to it sufficiently early. He referred to genuine cholera infantum, and not to entero-colitis. He had found that it would stop the vomiting; he also applies cloths wet with whisky to the epigastric region. Too much reliance is placed generally upon minute doses of calomel, and the brandy is left until it is too late. He agreed with Dr. Bartholow regarding the proper time of administering stimulants and the importance of proper dilution. Hypodermic injections of brandy or whisky in surgical cases lessen shock and the danger of hemorrhage. They should not be given with a view of counteracting the effects of ether, which should never be pushed to its depressing effect in such cases.

Dr. W. S. Stewart noticed that the stimulants in low fevers do not intoxicate the patient, and cannot be detected in the breath even after large doses.

Dr. C. H. Thomas said that the question whether alcohol is or is not a food is an important one; but there can be no question but that in many cases it acts like a food. He cited a case of a lady who received a severe nervous shock and was almost insane in consequence. She was constantly vigilant, would take no food whatever, and was rapidly losing flesh: in ten days she lost between thirty and forty pounds. It was determined, on the third or fourth day, to give her whisky, of which she took some every hour, amounting to a quart a day. At the end of the tenth day she slept well, and for the first time complained of the amount of whisky, which was rapidly reduced,—the next day to one pint, and the following day to half a pint. In a few days more after she had begun to take food regularly, she could not take a wineglassful of whisky without its flushing her face. In this case alcohol acted like a food, at least until other food could be taken.

Dr. Nancrede said that as a comparison had been made between the results of local use of alcohol and those of Lister's method, he would say that he was not an advocate of Listerism, but would inquire whether any surgeon in Philadelphia had adopted fully the genuine treatment as recommended by Lister. He thought not. We are therefore not in a position to speak of its results from experience.

Dr. Bartholow, in reply to a question, said that alcohol should not be given hypodermically to relieve the narcotic effect of ether or chloroform, because, having similar physiological effects and acting like them, it will only add fuel to the fire.

Dr. H. C. Wood, in conclusion, said that in regard to the question of alcohol acting as a food in childhood, it is paradoxical but true that if you wish to make a stunted child grow you should use alcohol, and if you wish

to stunt a child you can do so by alcohol, simply because small amounts aid digestion and large amounts disturb it and prevent assimilation. With regard to the non-appearance of alcohol in the breath in low fevers, he would account for it on the ground that the alcohol was used up in the system.

REVIEWS AND BOOK NOTICES.

A Manual on Diseases of the Eye and Ear. For the Use of Students and Practitioners. By W. F. Mittendorf, M.D., etc. New York, G. P. Putnam's Sons, 1881. 8vo, pp. 445.

A new manual of eye and ear surgery has been thrown into the arena,—we ask, what for? The author in his preface says, "The want of a short, practical manual of the diseases of the eye and ear in the English language has long been felt by the medical student. I have therefore," etc.,—the well-known apology.

"Fully illustrated"!—very fully. We turn page after page until we reach 285 before we find a single wood-cut, with the exception of two, showing Hotz's operation for trichiasis. Becoming anxious, we carefully turn and scan, when, to our great surprise, three well-known ones modestly look us in the face, and, in a half-frightened way, seem to say, "Oh, have you found us! we are so lonely." Following up the trail, we unexpectedly burst into what, at first sight, appears a fairy-land of promise. What do we see? The dear old Liebreichs: they greet us,—try to shake hands as cordially as they did when we were young. The dear old theoreticals, the typicals. We know that Wells used you until you became aged and decrepit; and here you come to meet us in your second childhood.

On page 193 we find that Daniel has been credited with a spoon; but what that poor man, in all his troubles, wanted with a cataract-spoon it remains for the author to tell us, as we cannot think he could spoon a healthy, unanæsthetized lion. Possibly the best way to find out would be to follow Dr. Holmes's proposition in the Mary Chase case,—subpœna Daniel.

A gross mistake is made on page 318, in confounding the visual angle with the angle existing between the visual axis and the optic axis.

In Graefe's test, on page 66, mention should be made of the crossed diplopia, to render the meaning complete.

On pages 142 and 181 we cannot agree that the most favorable place for artificial pupil is up and in.

Throughout, the pathology is borrowed from Alt.

On page 247, in speaking of central scotomata, we are not sure that the valuable hint of the patient not seeing the surgeon's nose, but his ears, when the visual line of the patient is pointed towards the tip of the surgeon's nose, is based upon experience; but of two things we are almost certain,—that either "the medical profession at large" for whom this book was written are all considered to be blessed with extensive auricles, or all central scotomata seen by the author have been exceedingly limited in area.

Space forbids us to enumerate the many defects in grammar, punctuation, and spelling, especially the spelling of the well-known names of Mariotte and Carmalt; and some of the formulæ would make good Jonathan Pereira sigh in his grave.

Possibly, with more careful proof-reading, the substitution of better plates, and the insertion of explanatory wood-cuts, the work may be rendered of great value, as it really contains a vast amount of practical information expressed in an easy and comprehensive style. C. A. O.

A Treatise on Diseases of the Nervous System. By Wm. A. Hammond, M.D. Seventh Edition. New York, D. Appleton & Co.

The most important changes in the present edition consist in the translation of certain articles affixed to the Paris edition of Dr. Hammond's book by the French editor, Dr. Labadie Lagrave. With these and the other less important changes the book is more complete than ever before.

A Medical Formulary. By Dr. Laurence Johnson. Wm. Wood & Co., New York, 1881.

We presume somebody uses books of the present class, else they would not be so persistently published. Why, with the aid of the "Pharmacopœia," the magister cannot invent his own formulæ to suit his individual cases, we never could quite understand. Not being able to appreciate the value of books of the class, we may very readily err in judgment as to the individual integers; but, so far as our judgment goes, the present volume seems to be good of its kind.

GLEANINGS FROM EXCHANGES.

Acute Prostatitis.—At a recent meeting of the Medical Society of London (*Lancet*, vol. i., 1881, p. 738), Mr. Reginald Harrison, of Liverpool, read a paper on acute prostatitis, of which he distinguished two forms,—the follicular and the parenchymatous. The former is most frequently seen as a complication of gonorrhœa, and suppuration is exceptional. In reference to suppuration and the insusceptibility of the muscular element of the prostate to inflammation, Bumstead's observations

apply accurately to follicular prostatitis. He says, "There is never at the outset an abscess of considerable size. Such occurs only by the coalescence of a number of small ones seated in the follicles. Meanwhile the muscular tissue which constitutes so large a portion of the prostate gland is unaffected, except that it is in a constant state of contraction, thereby inducing urethral and rectal tenesmus." The other form of prostatitis, the acute general or parenchymatous, is much more serious, the whole mass of the prostate becoming inflamed and tending to suppurate rapidly. Here, unless the treatment is prompt and decisive on the first appearance of fluctuation, as detected by rectal examination, the most serious results both to structure and life are apt to follow. It is a rare form of the disease, and usually found only in those whose constitutional powers are much deteriorated, or whose urinary organs have been more or less damaged by long-continued obstructive disease. Some instances which have been observed by Mr. Harrison have been apparently due to a previous state of tuberculosis of the gland. The occurrence of suppuration is to be carefully looked for, as the spontaneous escape of matter in such directions as the rectum, bladder, and peritoneal cavity is likely to be much more detrimental than the opening which the surgeon would afford. Gangrene of the prostate sometimes occurs as a result of inflammation. Inflammation and suppuration around the membranous portion of the urethra, not uncommon in gonorrhœa and phlebitis of the vessels forming the prostatic tissues, simulates prostatitis. The former presents many points of resemblance to inflammation of the gland, but is distinguished by the presence of perineal tumefaction and digital examination of the rectum. In the treatment of prostatitis the local abstraction of blood and hot applications are most efficacious at the outset of the disease. Hot enemata, as advised by Guthrie, and the injection of hot water into the urethra by means of a douche, are also to be recommended. Mr. Harrison is strongly opposed to the use of purgatives, as causing pressure to be exercised on the inflamed prostate by the levator ani muscle and being opposed to the principle of rest in the treatment of an inflamed part. The occurrence of suppuration is to be carefully looked for. Any formation of matter not to be detected by the finger in the rectum may with safety be left to evacuate spontaneously; when, however, fluctuation is in this way detected, a perineal incision becomes imperative. Incision is to be preferred to puncturing the abscess with a trocar by the rectum. Stress is to be laid upon the great importance of rectal examination in all these cases, or in those simulating it, and for this purpose, should the pain or tension be so great as to interfere with the thoroughness of the procedure, an anæsthetic is to be used. Dr. Pitman, of St. George's Hospital, has recorded a case where abscess of the prostate occurred as a sequence to gonorrhœa without any of the ordinary symptoms, and led to the death of the patient. An occasional consequence of follicular prostatitis is a more or less permanent dilatation of the follicles, and this is believed to be a not uncommon source of prostatorrhœa, a complaint well described by Professor Gross, and often very difficult to cure.

A Method of Treatment for Certain Kinds of Incontinence of Urine in Women.—Dr. Chapman, in a paper read before the Edinburgh Obstetrical Society (*Edinburgh Medical Journal*, June, 1881, p. 1095), referred to a class of cases, not those where incontinence is complete, but where on testing the bladder's retaining capacity it is found to be less than the normal. He gives in illustration the case of a married woman of 58, who complained of frequent and painful micturition which had lasted three and a half years. On September 30, 1880, it was found she could retain water only half an hour. The pudenda were reddened, as was also the whole vagina. The urethra was somewhat gaping at its outlet. There was considerable pain evinced on rubbing the two walls of the bladder over each other, or on introducing the sound into the viscus. The urine was turbid, acid, and contained pus cells, bladder-epithelium, and some oxalates. The urethra was dilated with the finger, with the result of increasing the bladder's retaining limit to one and a half hours. At the same time nux vomica and uva ursi were given, and the vaginitis treated by sedative applications. The good effects of the dilatation disappeared in about three weeks, and it was then repeated; but soon she again relapsed into her former condition, minus, however, the pain and the presence of pus in the urine. The urethra was examined by the endoscope, and a slight redness observed. Iodoform bougies were used. The condition of the bladder-wall as seen by the endoscope was normal, and now (November 8) her only trouble was that every hour—day and night—she had to empty her bladder. The total quantity of urine passed was fifty ounces, which gave little more than two ounces as the amount at every micturition. The sound passed into the bladder three inches from the external meatus, and it was found that it could be pushed only half an inch farther, and that thus pain was caused. It occurred to Dr. Chapman that gradual forcible dilatation of the bladder might relieve the patient. The bladder was distended with warm two-per-cent. carbolic acid solution, and the quantity used measured and found to be four ounces. Any attempt to inject more caused the most intense pain, and the resistance offered was great, as could be felt by the difficulty experienced in compressing the ball of the syringe. From this date the bladder was filled to distention daily, the injection

being stopped when the patient's pain became great and when resistance reached a high point. The apparatus used was a Higginson's syringe attached to an ordinary catheter, care being taken to prevent the access of air to the bladder. Each day there was a gradual increase in the amount injected, of from a drachm to an ounce. On two or three occasions the fluid as it returned was tinged with blood; but no harm ensued. On December 20 she was discharged in the following condition. Instead of micturating every hour, she had only to get up once or twice through the night, and by day she could retain water so well as not to be inconvenienced. Sixteen ounces could now be injected into the bladder, and less pain was thereby caused than formerly when four ounces was the limit. The urine was normal in all respects. Two months later the patient reported herself as continuing well in all respects.

Stertorous Breathing in Apoplexy and the Management of the Apoplectic State.—In a paper on this subject in the *British Medical Journal* for May 28, 1881, Dr. Robert Bowles says that the causes of stertorous breathing in apoplexy are mechanical, and can at all times be so changed as to alter altogether the nature of a case, and often to make the difference of recovery or death. The truth is, two separate conditions of the apoplectic state have been jumbled together and treated as one,—the cerebral affection and the condition of suffocation consequent upon it. Stertor in one sense is but a croup in the pharynx, or apoplexy *plus* suffocation, as croup is laryngitis *plus* suffocation. We feel it necessary to relieve croup by a serious operation; whereas stertor is left to itself, although it may be relieved by merely changing the position of the body.

Dr. Bowles divides the various forms of stertor commonly observed as follows:

1. *Nasal stertor* arises from paralysis of the nerves supplying the elevators and dilators of the alæ nasi, so that the ingoing air, as in sniffing, draws the alæ nasi towards the septum, and sometimes causes a serious obstruction to the breathing, and certainly hastens death, as well as needlessly distresses the bystanding and sorrowing relatives. It is often a symptom of the gravest kind, is unaffected by the position of the body, but may always be relieved by mechanical means.

2. *Palatine stertor* occurs when the air in rushing through the nose or mouth causes a vibration of the soft palate. It is usually of the least consequence; *i.e.*, it obstructs the breathing only very partially, and cannot always be removed by changing the position of the body. It is affected by the size of the tongue, the length of the uvula, the position of the chin, and other incidental conditions, all of which may be obviated if the obstruction to the breathing be sufficient to render it worth the doing.

3. *Pharyngeal stertor* is the most common in severe cases of apoplexy, when patients are recumbent. This may always be obviated by properly arranging the position of the patient, allowing the paralyzed mass—the tongue—to gravitate to one side rather than against the back of the pharynx.

4. *Mucous stertor*, when unconnected with lung-engorgement the consequence of suffocation from stertor, occurs only in very serious cases, depending upon interference with the nutritive processes of the lung-tissues, probably arising remotely from accident to or pressure upon the medulla oblongata. This can always be satisfactorily removed by proper attention to the position of the body.

These principles apply not merely to apoplexy, but also to all apoplectic conditions. Especially may be mentioned drowning, epilepsy, convulsions in children, meningitis with effusion, death-rattles, fracture of the skull, concussion, bronchitis (especially that of old people), sudden œdema of the lungs, large hemorrhage from the lungs, and also all conditions allied to the apoplectic, whether there be mucus or not.

A Case of Croup treated by Passing Catheters into the Trachea by the Mouth.—Dr. J. Wilson Paton (*British Medical Journal*, vol. i., 1881, p. 803) gives the case of a child of three years suffering with a cough following measles. This gradually increased in severity until one night Dr. Paton was called and found him suffering from intense dyspnœa, quite unable to speak, and his lips of a dark, livid color. The cough was constant, brassy, and without expectoration. The respirations were thirty-five per minute, the cartilages of the ribs and sternum being drawn in at every effort to breathe, and crepitation existing over both lungs. The fauces were healthy; the pulse was 144, very weak. Having a No. 11 prostatic catheter with him, Dr. Paton determined to pass it into the trachea instead of performing tracheotomy. Watching an opportunity while the tongue was depressed with a spoon, the catheter, curved a little more than usual, was passed into the trachea during an attempted inspiration, and without the slightest difficulty. A severe struggle followed, lasting perhaps a minute or two, the face becoming purple and the eyes staring with fully-dilated pupils. The paroxysmal efforts to expel the tube being unsuccessful, a pretty full inspiration, partly through the tube and partly through the larynx, followed; about two ounces of frothy, bloody, and purulent mucus were ejected by the tube and the mouth; the livid color disappeared, and the child lay down, breathing easily through the tube. The presence of the tube did not prevent his swallowing milk, although sometimes a little of this was ejected from it during a cough. The tube was retained *in situ* by a strip of plaster, and the teeth were prevented from closing on it by

means of a pear-shaped piece of hard wood.

Six hours later the little patient was much easier, though the cough continued. A bronchitis kettle was used in the room. The tube was removed without trouble after it had been in the trachea about eleven hours, as he had bitten it and no air was passing through it. Shortly after its removal symptoms of obstruction gradually reappeared, and an ordinary gum-elastic catheter, No. 12, was introduced, only a slight momentary struggle and cough supervening. The presence of the tube led again to a very free expectoration of mucus. In the course of a few hours the respirations and pulse became lower, and crepitation and dyspnœa ceased. When the tube had been in for forty-eight hours and a half it was removed, and not again introduced. Further recovery was rapid and complete.

Bromide of Potassium in the Convulsions of Children.—Dr. MacDonald (*Edinburgh Medical Journal*, 1881, p. 1094) says he has found bromide of potassium, preceded by a dose of calomel with sugar, a most efficient remedy for the convulsions of children. Recently he gave ten grains in four hours to a child seven months old, which was convulsed every half-hour, with perfect result, and this been followed in all cases. Four or five grains every four hours has generally been sufficient, with, of course, the ordinary adjuncts of bath and linseed poultice along the spinal column.

Acute Urticaria from a Single Dose of Iodide of Potassium.—Dr. Jordan Lloyd (*British Medical Journal*, May 21, 1881) gives the case of a man suffering from syphilis who took four grains of iodide of potassium in water, which was followed three hours later by an urticarious eruption. The rash appeared subsequently on several occasions after taking the same dose. Dr. Lloyd saw him once three hours after taking a three-grain dose. He then had a copious eruption of reddish indurations over the face, neck, and arms, but no gastric disturbance and no coryza.

MISCELLANY.

The Treasurership of the Pennsylvania Hospital.—The resignation of John T. Lewis, treasurer of the Pennsylvania Hospital, has been accepted by the managers of that institution, and Henry Haines elected as his successor. At a meeting of the managers held recently, a minute was adopted expressive of the esteem in which Mr. Lewis is held by the managers, and of the value of his long and faithful services. It stated that the charitable work of even old communities presents few, if any, parallels to the continuous and uncompensated service of the four members of the Lewis family, representing three successive generations and covering a period of over a century in the watchful and judicious care of the funds of the institution. The several terms of office of the four have been as follows: Mordecai Lewis, elected 1780, died 1799, eighteen years and eight months; Joseph S. Lewis, elected 1799, resigned 1826, twenty-seven years; Samuel N. Lewis, elected 1826, died 1841, fourteen years and eleven months; John T. Lewis, elected 1841, resigned 1881, forty years and three months.

Medical Lectures and the Law of Copyright.—In an editorial in the *New York Medical Journal*, Dr. Foster calls attention to the recent legal decision of the Supreme Court of the State of New York in the matter of Putnam's sons against Dr. Leo T. Meyer. The questions involved were,—1, the right of lecturers to retain full property in material which has been publicly delivered in the form of lectures, and, 2, the value of a verbal permission "to print" as affecting a formal contract to publish. The decision was in favor of the lecturer, who may now, if a man of some reputation, deliver his clinical lecture without fear of the garbling fiend on the back bench who is taking down his colloquial slips of expression while leaving out his wisest aphorisms, and who appears to glory in turning the wisdom of the sage to the drivel of the babbler in his "Clinical Lecture, by Prof. Bigbug, reported especially for the *Hospital Leaflet and Clinical Reflector*."

The Climax of the Antiseptic System.—At a recent duel, says the *Lyon Médical*, the adversaries were about to cross swords, when a voice called upon them to stop. It was that of the surgeon in attendance, who, imbued with modern ideas, taking from his pocket a bottle of carbolic acid carefully wetted the points of the weapons. He then exclaimed, with the air of a man who has done his duty, "Proceed now, gentlemen; you may kill each other, but at all events you are safe from purulent infection."

Fuming Inhalations in Asthma.—The following is the approximate formula of the quack remedy employed by the late Lord Beaconsfield with relief:

℞ Potas. nitrat., ℥ss;
Pulv. anisi fruct., ℥ss;
Pulv. stramonii fol., ℥i.—M.

A thimbleful placed on a plate is pinched into a conical shape, and, lighted at the top, burns like a pastile, and is held near the patient, who inhales the fumes.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM JUNE 26 TO JULY 9, 1881.

Koerper, E. A., Captain and Assistant-Surgeon.—Granted leave of absence for two months and fifteen days. S. O. 143, A. G. O., June 24, 1881.

PHILADELPHIA, JULY 30, 1881.

ORIGINAL COMMUNICATIONS.

WEAK EYES IN THE PUBLIC SCHOOLS OF PHILADELPHIA.

*THE REPORT OF THE COMMITTEE ON EXAMINATION OF THE EYES OF THE CHILDREN IN THE PUBLIC SCHOOLS OF PHILADELPHIA.**

BY S. D. RISLEY, A.M., M.D.,

Chairman of Committee, Lecturer on Ophthalmoscopy in the University of Pennsylvania, Ophthalmic and Aural Surgeon to the Episcopal Hospital of Philadelphia.

MR. PRESIDENT AND GENTLEMEN,—On June 22, 1878, I was honored in the reception of the following letter from the Recording Secretary of the Philadelphia County Medical Society:

"S. D. RISLEY, M.D.:

"DEAR DOCTOR,—At the stated meeting of the Philadelphia County Medical Society, held June 18, 1878, you were appointed chairman of a committee under the following resolution:

"WHEREAS good vision is of great importance in the career of every individual, its defects insuring more or less hindrance to success in life;

"AND WHEREAS many of these defects of sight, notably myopia, are caused or made progressive during school life, as is set forth by numerous investigators in other cities both in this country and in Europe;

"AND WHEREAS it is believed that proper attention to the lighting, seating, hours of study, character of type in text-books, etc. etc., will do much to obviate defects of sight:

"*Therefore Resolved*, That the Philadelphia County Medical Society respectfully request the School Board of Philadelphia to extend every possible opportunity to a properly authorized member or members of the Society to examine the eyes of the children in the public schools of Philadelphia, and to investigate all matters pertaining to their vision and the preservation of the same.

"The committee consists of five, as follows: yourself, chairman, A. Nebinger, L. Brewer Hall, A. G. Heyl, J. Collins.

"Very respectfully,

(Signed), "H. LEAMAN,

"*Recording Secretary.*"

Immediately on the receipt of this communication a meeting of the committee was called for consultation, resulting in the attendance of Drs. Hall and Collins, and a card from Dr. Heyl, declining to serve upon the committee.

A copy of the preamble and resolution was sent to the Board of Public Education for their consideration. The request conveyed in the resolution was freely granted, and the hearty support and co-operation of the Board assured. The proceedings of the Board were, as usual, published in the daily papers, and the great interest felt by the community in the work of your committee was at once manifested. The chairman of the committee was forthwith waited upon by numerous representatives from the various newspapers of the city. A long editorial notice of the nature and motive of the work proposed by the Society appeared in the *Philadelphia Press* of September 30, 1878, which closed with a request for the support and earnest co-operation of the teachers and parents. Many letters were received from private individuals, some of whom were the parents of children attending the public schools, tendering advice, making suggestions, or expressing gratification that so important a work had been undertaken. In this manner was indirectly expressed a deep anxiety regarding the vision of the school-children. Thus under favorable auspices the work was begun early in October, 1878.

At the request of Dr. Nebinger, the first examinations were undertaken at the George W. Nebinger Grammar School, in the southern section of the city. The directors' room was placed at the disposal of the committee, and everything possible done to facilitate their labor. It is appropriate that the thanks of the committee be tendered to Miss Bryan and Mr. Sharp for their kindness and courtesy in aiding your committee,—the former the principal of the Girls' Grammar, the latter the principal of the Boys' Grammar School, both of which meet in the same building.

The *personnel* of the committee as it appears upon the minutes of the Society has during the progress of the work been subjected to a number of changes. As already mentioned, Dr. Heyl did not accept the appointment upon the committee. It was understood that the part of the work falling to Dr. Nebinger was to look after the interests of your committee in the Board of Public Education. Dr. Collins very soon found that the demands of his private practice made it impossible for him to aid regularly in the work of the committee: so that Dr. L. Brewer Hall and myself were left with a

* Read before the Philadelphia County Medical Society, April 13, 1881.

work of no little magnitude resting upon us. In order to further the work of the committee, it was desirable that more aid should be secured; and we were successful in securing the valuable assistance of Dr. James Wallace, one of the assistants in the Eye Dispensary of the University Hospital, Dr. Heilman, of the Philadelphia Dispensary, and Dr. Eskridge. The thanks of the committee are justly due and are hereby tendered to these gentlemen for their skilful aid and the untiring diligence which for two school years, three times each week, found them at their post of labor. During the third year Drs. Francis M. Perkins and Gordon M. Christine generously consented to assist in the work, Drs. Wallace, Heilman, and Eskridge finding it impossible to continue their labors with the committee. Finally, Mr. President, I am indebted to Dr. B. Alexander Randall, who has been almost my sole assistant in tabulating the extended observations and in the preparation of this report, a labor the magnitude of which has exceeded very far my anticipations as well as my strength, when added to numerous other cares.

In presenting this report, Mr. President, I beg leave to state that the most that can be claimed for it is a report of progress. In the first place, we have been able to study the eyes of a very few hundred children, while the field before us contained upward of seventy-five thousand.

The opinions herein expressed, although seemingly justified by the collated facts, are not to be regarded as final; since a still more extended observation might make it necessary to revise too hastily formed judgments. During the progress of the examinations it has been found necessary to relinquish opinions before entertained regarding many things in the educational methods pursued in the public schools of Philadelphia; yet it is believed the opinions which have been formed should have some weight in the minds of the educators and those who direct their labors.

Having thus called attention briefly to the history of the formation and work of the committee, I ask your careful consideration of the motive of the work undertaken, and the important questions it was hoped the examination of the eyes of the school-children, during their educational process, might solve.

S. D. Risley, M.D.,
Chairman of Committee.

Having in view the great importance of good vision to the student, it is justly a matter for surprise and condemnation that so little care has been manifested by parents and teachers. Indeed, they seem to have been in most cases quite unmindful of the condition of vision in the pupils they propose to educate. Our children are sent to school without even the most cursory inquiry as to whether their eyes are fitted to perform the important and arduous duty before them in the long educational process; this, too, in the face of the fact that they are to be the most important agent in the acquisition of knowledge. The utmost attention is given to the teeth, lest through neglect they should decay; but the eyes are allowed to enter upon the important duties of school life without a thought of their welfare. Yet the importance of such supervision can hardly be overstated.

Perfect eyesight is not only necessary for the successful performance of the ordinary school duties, but has much to do in the formation of both the moral and physical characteristics of the individual. The boy who is constantly subjected to the painful eye-strain required to overcome an anomaly of refraction cannot, other things being equal, compete successfully with his more highly favored companions with normal eyes. Two courses only are open to him. He may by dint of perseverance and pain contend successfully for the prizes of school life; but he succeeds at the expense of injury to his eyes. On the other hand, finding the struggle a painful one, he retires from the unequal conflict, and is found, still a mere youth, contending for the rewards of life in mercantile or other pursuits. If compelled by parental authority to remain at school, the task, at best a difficult one, is either neglected or necessarily so imperfectly performed that it sooner or later becomes an impossible one. The class of which he is a member advances step by step from the rudiments to their application in the acquisition of real knowledge; but with each step he finds the difficulties thickening about him, since a knowledge of the rudiments is necessary to a proper understanding of what he is now expected to learn. Understanding these imperfectly, it soon becomes impossible for him to go on successfully: so he proceeds in a dazed way, deceiving his teacher and his parents, such deception being necessary to keep him from utter

disgrace. The book is smuggled into the recitation-room and slyly consulted to make up for deficiencies in preparation; or, at best, the memory instead of the understanding is called into action. Conscious himself of the inferior and unworthy position he occupies, he loses that self-respect which is always the bulwark of an honorable man, and finally passes out into the world with only the semblance of an education, and with elements in his character which are in a measure the creation of his defective vision,—elements of character which shall ever afterwards prove a barrier to the highest success; for the best prizes fall only into the lap of the honorable citizen. It is true that this may be regarded as the picture of an extreme case: it is one, however, which is too frequently exemplified in our midst. In a minor degree the same principle is operative in thousands of the children attending our public and private schools to-day.

If near-sighted, the effect over the character of the individual manifests itself even earlier in life, possibly in a less pernicious way so far as the moral character is concerned, but with a deleterious effect over the physical constitution, mental habits, and manners of the individual. The peculiarities of the near-sighted person are so marked that, if the defect has not been corrected early in life by optical means, the most casual observer recognizes him among his fellows. The proneness to sedentary pursuits, and the habit of abstraction and apparent disregard of friends and acquaintances in places of public resort, are facts noticed and condoned. That these characteristics of the myope depend upon his near-sight we need not go far to show. The near-sighted boy, *e.g.*, cannot fairly compete with his more fortunate fellows in the sports of the playground, since their requirements lie beyond the range of his vision. An attempt at cricket or base-ball must necessarily subject him to the ridicule of his companions, since, thrown even from his own hand, the ball soon leaves his range of clear vision and he is unable to judge of the accuracy of its flight. In returning, it comes within his limited area of distinct sight, if perceived at all, so suddenly that the most dexterous movements cannot compensate for the loss of time in perceiving its approach. Thus, in consequence of a physical defect, of the existence of which he may himself be entirely ignorant, he is driven from the campus by the ridicule or neglect of his fellows,—a very natural result of his inaptitude. The invigorating out-of-door sports are one by one sacrificed to more sedentary pursuits. He reads constantly, not as a matter of duty or from a desire for knowledge, but because it is the only pastime left open to him. The habit grows upon him, and he reads apparently for the sake of reading, with no thought of the acquisition of knowledge. The constant reading gives no time for reflection or the proper comprehension and digestion of what is read. A condition of mental engorgement is thus brought about, which is as foreign as possible to a true educational process. Such a child is less troublesome than the wild and rollicking boy with his ball and bat and ruder manners, and so his sedentary habits come to be encouraged. He is regarded as studious, and too frequently as a prodigy of learning: so it constantly happens that his inordinate craving for books is fostered instead of condemned, the vain hope being entertained that in the future all this devouring shall prove the basis of brilliant literary accomplishment. He becomes retiring and diffident. Away from home amid strange surroundings the myope is hesitating and cautious. He goes out into the world devoid of that practical skill which characterizes the successful man of affairs; for it must be remembered that his defect of sight is operative at all times, not only on the college campus, causing directly his inaptitude there, but playing an important rôle in all the details of life. As the partially deaf child with good vision depends for his understanding of conversation largely upon the facial expression and movements of the lips of the speaker, and loses the lower tones and least accentuated parts of the spoken sentence, and thereby learns to talk in broken angular sentences; so the near-sighted child learns to rely upon the tones of the voice, since the facial expression of the speaker is not seen. He is thus more readily deceived, since he loses this great aid in the interpretation of individual character. He hears the bustle and noise of the busy world around him, but does not readily throw himself into the current of passing events. He hears the talk about the beautiful landscape, but it is all a blur to him. He thus, as a matter of compulsion, occupies a world of his own, constituted by his narrow range

of vision and the ideals built up from his extended reading of books, without the possibility of comparing the descriptions of the author with the realities in nature. Within this limited world it is natural that he himself should be the most prominent factor.

If then these deductions are well drawn,—and we believe they are justified by daily observation,—if not only the physical constitution but the mental habits and moral character of the individual may be subject to serious impairment and modification in consequence of defective eyesight; it becomes a matter of serious moment to every community to avoid, as far as may be, the occurrence of defects of vision, and, when present in the individual, to neutralize, if possible, the consequences of such defects.

That various defects of sight exist in eyes which are thought to be perfect by both parents and teachers, is a fact well established by the daily observation of every ophthalmic surgeon, and demonstrated by the extended observations of numerous investigators in the schools of Europe and the United States. It has been shown by these observers that one of the most important of these defects, namely, myopia, is present in very much larger percentage in the advanced classes. That is to say, it was proven that near-sight was acquired by a large number of school-children who began the educational process without such defect in their vision.

This main fact had been repeatedly demonstrated; nevertheless but little light had been thrown upon the essential cause or causes of the increase in myopia, or upon the history of the ocular changes. Based upon these facts, important suggestions, it is true, had been made regarding the hygiene of vision; the proper relation of seats and desks, sufficient light, etc., were insisted upon as important; but further than this no practical results were reached. It was therefore desirable that this investigation should, if possible, reveal something of the real cause of the myopia. That the hygienic surroundings of the pupils were not solely at fault was rendered probable by the investigations of Just, who examined the eyes of 1229 of the pupils in the two high schools of Zittau; both of which had been erected since 1866, and in which the hygienic conditions were all that could be desired. He nevertheless did not find that the excellent arrangements had in any degree lessened the percentage of increase in myopia. It was necessary, therefore,—the fact of the increase being established,—to look beyond the mere hours of study, the proper seating and the sufficient lighting of the school-room, since the most perfect arrangements in these respects had failed to arrest the increase.

The examination of large numbers of eyes in the schools had served to demonstrate the fact that myopia was more frequent in the advanced, than in the primary classes; and thus fully justified the inference of an increase in the number of myopic eyes in the same class as it passed from the lowest to the highest grade; but such investigation could not give the pathological history of the change in form of the eyeball. This, however, was necessary in order to arrive at a perfect knowledge of the real cause and nature of myopia. This history could in fact be acquired only by patiently examining the eyes of a large number of the *same pupils* year after year, and carefully recording their condition as they passed from the primary classes into the succeeding higher grades. Now, such a task presented extraordinary difficulties, and was one, withal, liable to many disappointments; since, as we shall show, the pupils, in whose eyes the investigator would be most interested, are the very ones who—in this country, where education is not compulsory—are apt to drop out of the class, because of the pain and consequent inability to pursue their studies.

The same result, however, it was thought, might be reached approximately by a careful study, in a large number of eyes, of the refraction, and also of the attending conditions of health or disease as revealed by a careful ophthalmoscopic study of each individual.

That the myopic eye was generally also a diseased eye was a fact well understood, since it found demonstration in the daily experience of the ophthalmic surgeon. The collated statistics had shown not only a steady rise in the percentage of myopia, but a nearly proportional decrease in the number of hypermetropic eyes, while emmetropia remained nearly uniform. The question, therefore, very naturally arose as to *whence came the near-sighted eyes.* It was obvious that they were recruited from one or both of the other kinds of eyes; yet actual satisfactory observation of such change had been wanting up to a very

recent date. That such changes must and do take place was, however, inevitable, in view of the facts set forth by the statistics. Now, since myopia was attended with well-known pathological conditions, which without a doubt stood in the relation of cause, it was fair, reasoning *a priori*, to suppose that the conditions of disease which resulted in distention of the eyeball, or near-sight, would be manifested some time before the resulting distention. If this were true, a careful study of the condition of the *fundus oculi* in all states of refraction would furnish the strongest obtainable evidence of the source of the unhealthy myopic eye. That is to say, if it were shown by such examination that, next to myopia, emmetropia presented the greatest percentage of diseased eyes, and hypermetropic refraction least of all, it might with some show of reason be accepted as proof that the myopic eyes were recruited from the intermediate emmetropic eyes. Indeed, this might still be accepted as true if emmetropia and hypermetropia presented an *equal* percentage of disease. If, on the other hand, it should turn out that emmetropia was the condition of health, and that hypermetropia presented the highest percentage of disease, then the conclusion would be reached, not only that myopia was recruited from eyes with hypermetropic refraction, but further that, despite the comparatively small number of actual emmetropes, emmetropia was nevertheless the condition of normal refraction, since it was the condition of health. Furthermore, the added conclusion would be inevitable that an eye with hypermetropic refraction was a defective eye, and that there must be a relation of cause and effect between this defect of refraction and the diseased *fundus oculi;* and hence that with such defective refraction in a large percentage of the eyes themselves, even a perfect system of instruction, with perfect arrangement of seating and desks, with sufficient light, ventilation, etc., would not avail in checking the progress of myopia.

It was with these views in mind that the work of this examination was undertaken; and in order to give the statistics a true value the utmost care was exercised throughout to avoid inaccuracy.

The method of examination which should secure the most complete record possible of the various facts to be ascertained by the investigation was a subject which received most careful preliminary study; and that adopted has seemed to satisfy the necessities of the case. Each child, on entering, received a printed form with blanks for the recording of all the important features of the case. To one member of the examining committee was assigned the duty of noting, in proper order, the name, age, sex, residence, color of eyes, hair, and complexion, the condition of general health, and the condition of the eyes. Under the latter headings were recorded whether the eyes were comfortable or weak when used, the presence of blepharitis, conjunctivitis, corneal maculæ, or strabismus, and any other condition or fact bearing upon the general medical history of the case.

The pupil then carried the paper to a second examiner, who ascertained by the test type of Snellen, and recorded, the sharpness of vision of each eye separately. A third tested by means of Green's astigmatic cards at twenty feet as to the presence of astigmatism; and if lines were positively selected as seen better in one position than in any other, the fact and the position selected were noted, any uncertainty being indicated by an interrogation-point. A fourth then determined the near-point and range of accommodation of each eye separately with No. 1 of Jaeger's test types, and examined as to insufficiency of the internal rectus muscles at twelve inches. To determine this, a 9° prism was employed to give vertical diplopia, and then, if with Graefe's dot and line, or a modification of it by the substitution of a word of Jaeger No. 1 for the dot, there were distinct crossing of the images, insufficiency was noted as present. The central color perception was then tested at twenty feet by squares on the same scale as the type of Snellen, and the result recorded in the same manner as the sharpness of vision. The color sense was further tested in matching colored worsteds after the method of Holmgren, and any fallacy from ignorance of the names of the colors in the preceding test completely excluded.

With the paper upon which all these data had been recorded, the pupil then entered the dark room for the ophthalmoscopic examination, which was made by the chairman of your committee, aided by the facts previously ascertained. The refraction was determined with the ophthal-

moscope with all possible care, and any error and its apparent extent recorded. Then the *fundus oculi* was studied in detail, and any departure, physiological or pathological, from the normal accurately described, and, where permitting of representation, sketched upon the paper. So carefully was this done that, in the subsequent study of the work, a glance at the sketches was often quite sufficient to bring up vividly to mind the entire ophthalmoscopic picture and other details of the case, which the name, etc., did not in the least recall.

As it was upon this ophthalmoscopic determination of the condition of refraction that most of the subsequent work hinged, it will be proper to state that all sources of error were excluded with the most painstaking care. The sharpness of vision and the range of accommodation previously recorded were carefully borne in mind, and used as checks to guard against mistake; and if there appeared to be the slightest inconsistency between them, care was redoubled to find the source of variation. If the vision were normal, myopia was at once excluded, and every means was employed to remove any spasm of accommodation which might simulate it; and the examination prolonged until the apparent error had disappeared, often to give place to a distinct hypermetropia. In the examination emmetropia and health were always presupposed, and the contrary was recorded only when unmistakably present. The average time required and actually spent upon each case was twenty-eight minutes, and the record thus obtained was as complete and free from all sources of error as was possible from a single examination, unless a mydriatic were employed; and upon it I should not have hesitated to venture an opinion or prescribe treatment, had that been the object of the diagnosis.

The records thus obtained were arranged according to schools and classes and copied into a book ruled and printed for the purpose; the original papers being carefully filed away. The individual results having been thus gotten into readily available form, the work of classification commenced; and it may here be stated, parenthetically, that not until the latter work approached completion had your committee more than the most vague idea of the ultimate showing of the investigation. The records were taken a class at a time, and the number of pupils, the number of eyes, and the average age ascertained for the class. The eyes were then classified according to their state of refraction,—columns being arranged for emmetropia, hypermetropia, hypermetropic astigmatism, myopia, myopic astigmatism, and mixed astigmatism; the number of each contained in the class being placed under the appropriate heading, and the percentage to the whole number of eyes in the class computed. Within each column were arranged headings under which to record the number of eyes of that condition of refraction that were comfortable at work, and how many uncomfortable; the number with normal, and with lowered vision; how many had healthy eye-grounds, how many unhealthy; the number with conus, with central excavation, with anomalies of the ocular muscles; and the percentage of the whole number in the column represented by these carefully calculated. The total number of eyes in the School of Practice was then found to be 456; in the Grammar School, 859; and in the Girls' Normal School, 1107; making a grand total of 2422. The results thus obtained were arranged in tabular form in the order of classes and schools, from the lowest grade to the highest; and the totals for the schools worked out, with the percentages as before. An example will make this clearer. In class B, section 4, Girls' Normal School, there were 74 pupils, with 147 eyes, and the average age was 17½ years. Of these, 21, or 14.35 per cent., were emmetropic, 55, or 37.41 per cent., hypermetropic, etc. Of the 21 emmetropic eyes, 14, or 66.7 per cent., were comfortable at work, 7, or 33.3 per cent., uncomfortable, 20, or 95.2 per cent., had normal vision, 18, or 90 per cent., had healthy eye-grounds; and so on through the other groups.* Another table was also prepared, dealing with the refraction alone; and in its second part the matter of astigmatism, important as it is, has been ignored, in order to give results comparable to those of other investigators, who have grouped under the head of myopia all eyes with myopic refraction, and as hypermetropia those with hypermetropic refraction, with-

* The preceding details were prepared in the expectation that these tables would form part of this report, and have been allowed to stand, although no longer necessitated in the absence of the tables; which have been reluctantly withheld because of the practical difficulties in the way of their reproduction.

out regard to whether the error was simple or complicated with astigmatism.

To render more distinct and comprehensible the results thus obtained, the graphic method has been employed, and curves used to indicate the proportional rise and fall of the various conditions. A little study of the classes included under the Primary school, of 11.74 per cent. in the Secondary, of 11.14 per cent. in the Grammar, and of 12.28 per cent. in the Normal; a variation of slight amplitude, which shows that the proportion of emmetropia was practically the same in all the schools, but tends slightly upward. H., however, presents a different picture.

TABLE I.

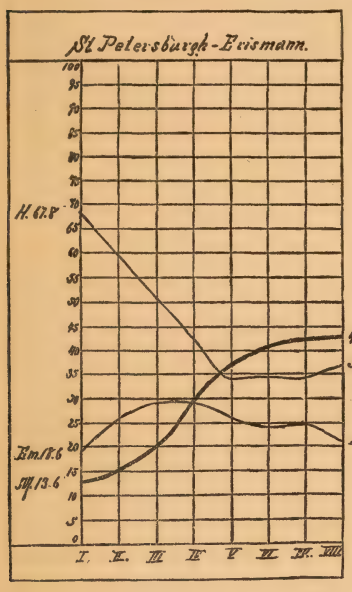

TABLE II.

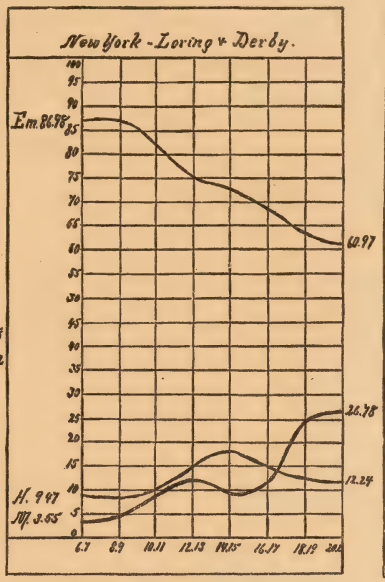

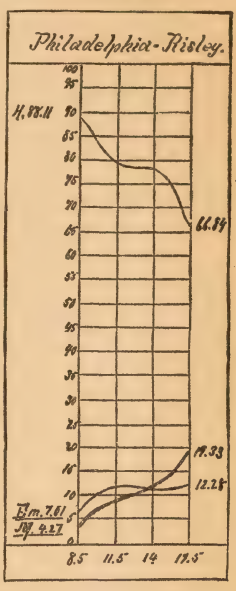

TABLE III.

the headings of the two lower schools at once convinced us that the divisions they formed were accidental. The classes were therefore rearranged according to their recognized grade, as Primary, Secondary, and Grammar, while the Normal School, as a whole, formed the fourth grade. The totals and percentages of these, with the average age of the pupils of each, were then carefully worked out, and upon them the tables of curves have been based. Thus, in Table III. the horizontal lines represent the percentages, the vertical lines which they cross, the Primary, Secondary, Grammar, and Normal Schools, in the order named; the average age of the pupils of each being given below. In this as in many other parts of the report, the abbreviations Em. for emmetropia, H. for hypermetropia, and M. for myopia, have been used; and in other tables H. As. for hypermetropic, M. As. for myopic, and Mx. As. for mixed, astigmatism.

Turning to the table, then, we see that Em. was the condition of 7.01 per cent. in Beginning with 88.11 per cent., it falls in the Secondary school to 78.92 per cent.; remaining at nearly the same level in the Grammar school, it sinks in the Normal School to 66.84 per cent., a total fall of nearly 22 per cent.

It is this fall of the hypermetropia curve, together with the nearly corresponding rise of the myopia curve, which freights this investigation with such serious meaning. Regarding the increase in myopia thus depicted, all authorities have shown, and this report will probably make still further evident, that it means at least a permanently defective vision, with its attending discomforts and disadvantages, for which our best skill can afford only palliative measures for relief. It will be noticed, then, that the myopia curve, beginning with 4.27 per cent., mounts with an almost unvarying course through 9.03 per cent. and 11.45 per cent., to reach in the highest school 19.33 per cent., an increase of full 15 per cent. That this increase of myopia is not exceptional in its extent, similar in-

vestigations are unanimous in proving. The results of two such are represented for comparison in Tables I. and II. Compared with ours, the curve drawn by Loring and Derby to represent the increase of myopia which they found in the eyes of 1133 school-children in New York City will be seen closely to agree. The smaller numbers in the divisions of classes of these gentlemen bring the higher and lower extremes into greater prominence, but leave more room for accidental variations; and their curve is distinctly less uniform. This does not, however, account for all the difference between the two showings; and even leaving out their last division, and comparing their seventh with our last, the average age in which is nearly the same, their proportion of myopia is seen to be full five per cent. higher. Another remarkable difference between the tables, and one which seems inexplicable, is that emmetropia and hypermetropia seem to have exactly changed places,—a phenomenon which has its parallel in the table of Conrad of Königsberg, but is at variance with the results of most observers. Between the curves of Erismann and ours the most distinct parallelism is evident; yet we can comfort ourselves with the observation that, injurious as our school-work is, and bad as is the outlook for the future of the eyes of our school-children, it is far better than in the Russian schools; while a comparison with the German tables would show even greater cause for congratulation. In the table of Conrad, already referred to, but not here given, the percentage of myopia in the University classes is seen to reach 62.10 per cent.;—*nearly two-thirds of the students are near-sighted.* Can we wonder that the spectacles seem almost an essential part of the physiognomy of the educated German? Nevertheless our table, like the results of all other observers, shows a nearly steady increase in the percentage of myopia during the educational process; and the evil, though not so great, is as real in America as in Europe, and its causes and the means of prevention as distinctly demand study.

But first let us gain a fuller understanding of the magnitude of the evil in its general bearings. To some persons the fact that near-sightedness is increasing may seem a matter of little moment. Objects have to be held nearer to the eyes, and a glass has to be employed to give any distinct distant vision; but, as an offset to these inconveniences, there is an idea quite prevalent that "near-sighted eyes are strong eyes," based on the fact that much later in life than other people, if at all, do myopes require the aid of a reading-glass. A study of Tables IV. and V. will by no means bear out this view. In these tables the method of representation is the same, but the eyes of hypermetropic and of myopic refraction have been further divided according as they presented the error in its simple form or as astigmatism. A column has also been placed for mixed astigmatism, although the small number of cases of this form of error of refraction leaves too much room for accidental variations for its indications to be of any great value.

In Table IV. the upper curve indicates the proportional frequency of unhealthy conditions in eyes of the different states of refraction; and it may be well here to reiterate that in this category were included only distinct departures from health. They varied from retinal irritation, with congestion of the nerve, striation of the retina, and undue redness of the entire eye-ground, to marked neuro-retinitis, choroiditis, or posterior staphyloma. The percentage of these conditions in emmetropic eyes will be seen to have been 31.97 per cent.,—a frequency which is explained in part by the fact that the eyes in the lower school were subjected to less favorable hygienic surroundings, and, further, that the other eye of the same pupil was often of a different refraction, and to it could fairly be charged the diseased condition which affected both. Only 20 per cent. of the emmetropic eyes in the Normal School presented these pathological eye-grounds; but even here the difference of refraction in the eyes of the same individual was present in a large number of cases, thus causing a higher percentage than though such difference had been eliminated. In hypermetropia the percentage passed 50 per cent.; in hypermetropic astigmatism, 76 per cent. Myopia presented disease in 82 per cent., and in myopic astigmatism 87 per cent. of the eyes were unhealthy. In the Secondary classes there was not found a single myopic eye in which the fundus was healthy; and even in the Normal School the diseased eye-grounds were present in nearly 82 per cent. of the myopic eyes. It would here be well to state that while some of the

classes in the Primary and Secondary schools had bad hygienic surroundings,—and in the Grammar schools the arrangements were not the best,—in the Normal School the greatest possible care had been given to the lighting and seating of the class-rooms, with the result of making them as nearly perfect as possible in the present state of knowledge of the requirements. Yet, in spite of this and of the fact that the pupils were much older, and therefore, as we shall show, less susceptible to unfavorable circumstances, the showing for myopic eyes was almost as bad as in the lower schools.

Turning now to a special form of disease of the eye-ground, known in its fully-developed condition as the "myopic conus," or "posterior staphyloma," and long recognized as of more or less serious pathological import, though of uncertain causation, let us trace its relation to the errors of refraction. The lower curve of Table IV. shows that this was found, often only in its incipient form, in 13.15 per cent. of the emmetropic eyes. In hypermetropia it was found in 20 per cent., and in the cases where astigmatism was combined with the hypermetropia it rose to 45 per cent. Myopia, with which many have claimed that conus was almost synonymous, presented it in but 41 per cent., distinctly less often than hypermetropic astigmatism; and only where myopia was itself complicated with astigmatism did the percentage of conus rise higher,—there, however, to reach 60 per cent. The changes in the eye-ground to which this name is here applied are almost infinite in variety and extent; but the study of the anatomical condition and its clinical history justify the statement *that it is a limited choroiditis, of varying extent and intensity, affecting the region of the nerve-entrance, and generally manifested at the temporal margin of the optic disk, as a crescent of altered color and pigment-absorption.* The massing of pigment in the ring of choroid immediately surrounding the nerve is a phenomenon more often present than absent, and is occasionally most extraordinary in extent in the eyes of young children; and while this last fact does not exclude the possibility of pathological meaning, since marked conus has been seen in infants, it still strengthens the testimony drawn from general observations that this is one of the matters which may be set down as physiological. But when the pigment about the disk begins to absorb, we can no

TABLE IV.

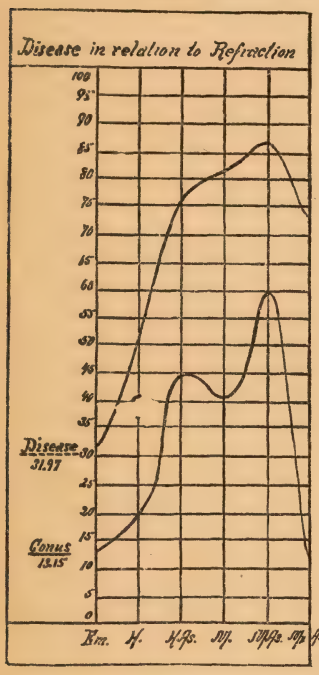

TABLE V.

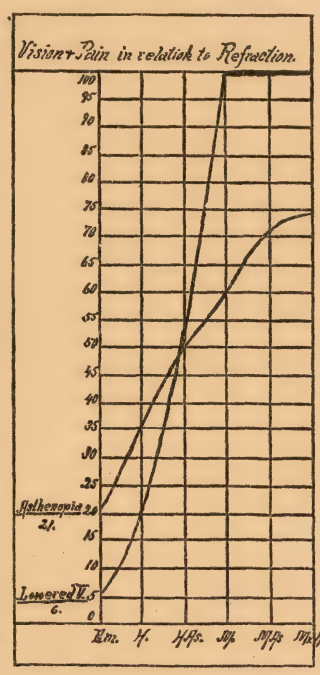

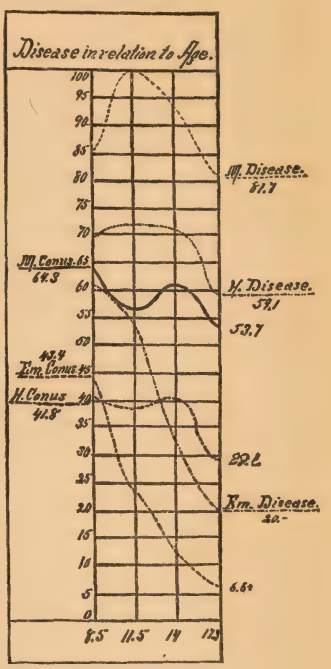

TABLE VI.

longer maintain such a view: the attending symptoms and the clinical history as derived from individuals and from classes point emphatically to diseased action with a marked and more or less permanent anatomical lesion. It is not our purpose here to enter upon the discussion of the vexed question of its causation; but we may well call attention to the emphatic pointings of the curve which shows its relation to errors of refraction, especially astigmatism.

In Table V. another important point is brought forward. One of the important facts recorded in the examination was whether the eyes of each pupil were comfortable when at work or asthenopic. In the latter category were included all the eyes which were painful after work, and also those which, though stated to be comfortable, gave distinct external evidence to the contrary,—*e.g.*, in frequent styes, blepharitis, conjunctivitis, and such affections. This latter check, which was used but sparingly, was rendered absolutely necessary by the utterly inconsistent statements of children. Experience shows that they are not prone to complain even when it is most evident that they suffer discomfort. In working up the results of the examinations, hundreds of eyes claimed to be comfortable were found with conditions making it impossible to accept the statement as true; yet the trouble was "not proven," and the eyes were recorded as comfortable. The relation of this matter of discomfort to errors of refraction needs no comment. The steady and rapid rise of the curve to 72 per cent. in myopic astigmatism is sufficient evidence of the dependence. Defective vision, as indicated by the other curve, increases with a sweep that would startle us if it were not a fact which familiarity has robbed of much of its weight. Yet it is worthy of note that there are few persons whose eyes are hypermetropic, even when a considerable degree of astigmatism is also present, who will not claim to have perfect vision. Only by an accurate test is the contrary made evident; and that, as the curve shows, only in a small percentage of the cases. The few who recognize the defect in vision almost invariably lay it to the charge of near-sight, and not infrequently seek aid from concave glasses.

Table VI. shows some points that were a genuine surprise to your committee, and, so far as we know, have never before been brought up. Here the percentages of disease in general, and of conus, are depicted in relation to age or class, and the remarks previously made regarding the hygienic surroundings of the various classes should be borne in mind, as well as the matter of the decreasing susceptibility, as age advances, to injury from such environment. Thus we see that in the Primary school the emmetropic eyes (a small number, however, in all) presented conus in 43.4 per cent., and diseased conditions in 60.8 per cent. The hypermetropic eyes had conus in 41.8 per cent. and disease in 69.5 per cent., while in 64.3 per cent. of the myopic eyes conus was present, and disease in 85.7 per cent. It is no wonder that it was with the most serious foreboding that we looked forward, when at the beginning of our work among the youngest children we found such a condition of affairs. The results obtained in the higher schools serve to lessen in some measure this impression; but it is a sad thought which arises when we look back and speculate as to the subsequent history of the individuals forming those primary classes. In the Secondary school conus had fallen to 23 per cent. and disease to 53 per cent. among the emmetropic eyes; in the hypermetropic the variation was slight, while among the myopic, though conus had declined to 56.6 per cent., disease had gone up to 100 per cent.: there was not one of them healthy. In the two upper schools diseased conditions steadily declined, except conus among the hypermetropes and myopes, which rose in the Grammar school to fall still lower in the Normal. In the Normal School, where the educational process was at or near its completion, the showing was far more favorable. Of the emmetropic eyes, only 20 per cent. were diseased, and only 6.6 per cent. of these had conus. Of the hypermetropic eyes, 59.1 per cent. were diseased, with conus in 29.6 per cent., while among the myopic eyes 81.7 per cent. were diseased, with conus in 53.7 per cent.; a showing which is an improvement, indeed, upon the preceding classes, but none the less sad for a model school. But the point exciting surprise, and perhaps forming a check to any congratulation over the preceding matter, needs to be touched upon. In Table IV. disease and conus have been shown to be most frequent among eyes of myopic refraction, and in Table III. my-

opic refraction has been demonstrated to increase as we pass from the lower to the higher schools; and yet the tendency of all the disease and conus curves is downward,—*i.e.*, upward as we pass from emmetropic, through the various defects of refraction, to myopic astigmatism, but even in eyes with these latter defects present, the curves tend downward as the age and class advance. That this should be the case among emmetropic eyes was to be expected, and even among the hypermetropic was readily explicable; but that it should be found among the myopic, lacks as yet any thoroughly satisfactory explanation. There are, however, a few circumstances which go far towards explaining this unexpected result. In the first place, the pupils in the Normal School were far more favorably situated than were those in the Grammar school. Half of the pupils in the Secondary school were in the same building and with much the same surroundings as the children in the Grammar school. The other half, however, were in the Normal School building, and they, with the Primary school, constituted the "School of Practice" of the Girls' Normal School. The arrangements in this Normal School are seemingly perfect. The quantity and direction of the light leave nothing in this respect to be desired, while the seating, placing of blackboards, and so forth, have been wisely done. The classes are not confined to any one room during the school-hours, but pass from one to another through broad and airy corridors for the successive recitations. Very little, if any, study, however, is done in the school-building, the lessons being prepared at home; a fact to be alluded to later. (The pupils of the Normal School are admitted from the various grammar schools throughout the city, the terms of admission being a certain class standing, which is the basis of promotion. Not unfrequently the pupils, when asked about the condition of their eyes, remarked that they had suffered greatly while in the grammar school, but had been more comfortable in the Normal School,—a distinct testimony to the favorable hygienic surroundings of the latter, since there was little if anything in the requirements of the course to make the difference.)

The children in the School of Practice, ranging from five and a half to twelve years of age, were, with the exception of two classes, quite as favorably placed as the pupils in the Normal School. These two classes, however, were very unfavorably situated. Owing either to the crowded condition of the building or to the necessities of classification, partitions about seven feet high, composed in part of ground glass, had been in two cases erected across a room. In the additional rooms thus secured there were no windows, sole dependence for illumination being placed upon the diffused light reflected from the walls and ceilings. At a desk in one of these rooms, on a bright clear mid-day, it was found extremely difficult to read Jaeger No. 1, in consequence of the imperfect illumination; yet in these rooms the classes occupying them not only recited but prepared many of their lessons, and this during a period of six months. The results of this arrangement on the eyes of the pupils were only too plainly revealed by the ophthalmoscopic examination. A large number of these little children were suffering from headache. They had congestion of the conjunctiva, and red and scaly lid-margins, while very many of them when asked if their eyes were troublesome replied, "They water when I study." The ophthalmoscope showed in most cases choroido-retinal irritation, and in not a few instances actual inflammation. It was here that was most frequently observed the commencement of those choroidal changes already described as occurring in the region of the optic disk. Many of the eyes were unduly sensitive to the light of the ophthalmoscopic mirror, and even during the preliminary examination would flush up and manifest their irritability by excessive lachrymation. These conditions, though worse in the two classes above referred to, were by no means confined to them. The irritable, overworked condition of a large percentage of the eyes of these young children could not but awaken the gravest apprehensions. That these classes did not show a percentage of disease very much in excess of the others is explained by the fact that many of the other classes had already occupied these same dimly-lighted rooms, having in the course of promotion passed through them. The better condition of the eyes in the secondary school furthermore suggests very forcibly the probability that many of the children with bad eyes in the primary classes had dropped out in

consequence of their eye-trouble,—a process which may be continuous through all the classes.

These facts, then, possibly furnish all the needed explanation for the downward trend of the curves in Table VI. One fact, however, has not yet been dwelt upon with the urgency its importance demands. Allusion is made to the bad condition of the eyes in the primary classes. Although the myopia curve is here at the bottom of the scale, the disease curves at eight and a half years of age are all high, even in emmetropic eyes. The lesson it is desired to impress just here is that in the eyes of these young children was being laid the foundation, in intraocular disease, for a future myopia. Protected at all other points by the watchful care of parents, they had nevertheless been subjected to the duties and cares of their early school life without a thought regarding their eyes, without the most cursory inquiry, except in rare cases, being made as to whether the eyes were fitted to perform safely their important function.

Although the limits for publication by the Society have been already exceeded, reference must be made to one other fact, since it suggests an important practical point in the architecture of school-houses. The two senior classes in the grammar school were seated in large, airy, well-lighted rooms, with every necessary appliance; but the desks were so arranged that the pupils sat facing directly three large western windows. Almost without exception these pupils were found with retinal irritation, and complaining bitterly of the source of light in the school-room. The fact that facing the light during work is a source of harm to the eye is one very generally recognized by the laity, and more than one letter found its way to the chairman of your committee, insisting upon its importance as the source of weak eyes.

There are numerous other suggestions, which should find place here did space permit, regarding the methods pursued in our public schools; but they must be reserved for more extended treatment elsewhere.

By no means, however, is the subject exhausted by the study of the eyes themselves, and by the discussion of the system of instruction in our schools. In conversation with many pupils who chanced to be suffering even beyond the average of those with bad eyes, they were free to confess that, after their lessons had been learned,—*i.e.*, those lessons they were required to prepare at their homes,—many hours, often extending far into the night, had been spent in reading. Of course the schools must not be held responsible for this evil, and a wide-spread evil it is, in this country. The ready access to public libraries, the cheap editions of works of fiction, and the great prevalence of Sunday-school libraries, etc., place a most fascinating form of literature in the reach of every one. It consequently happens that in the great majority of city homes, the younger members of the family may be seen, during the long winter evenings especially, poring, hour after hour, over a book. To add to the danger from this protracted strain upon the accommodation, the book is quite likely to be held in the lap, and the trunk and head bent forward over it; while a seat in some part of the room remote from the light is quite as liable to be chosen as a more favorable one. While these things are permitted at home, it is, of course, not just to accuse our school system. There is one of their methods, however, justly open to blame,—viz., the custom of giving tasks in the school-room which must be accomplished at home, often at the sacrifice of several hours of time which should be spent in out-of-door sports.

Among the questions of greatest interest which at the outset of this investigation presented themselves were:—

First. Would our more youthful civilization yield different results, regarding the percentage of increase in myopia, from those reached by European observers?—This was important as tending to shed light upon the possible heredity of myopia. This latter could be fully answered only by a careful study of the family history of a large number of myopes. My statistics and the records of private practice have placed this within reach, but time has not permitted its development. The question as stated has received a decisive answer.

Second. Myopia having been found to increase during school life, *did the increase come from the emmetropic eyes while they were recruited* pari passu *from the hypermetropic?* i.e., *did the eyes with hypermetropic refraction pass through emmetropia to swell the percentage of myopia?* This

involved the question as to which is to be considered the model eyeball.

Third. What relation, if any, existed between our educational process and the increasing percentage of near-sight, and to what extent were imperfections in our school-system responsible for the increase?

These questions, and many of secondary importance involved in them, have received answers in the preceding discussion, which are again summarized in the following conclusions, and are, we believe, fully justified by the preceding facts.

First. That the emmetropic eye is the model or standard eye,—since emmetropia was shown not only to remain nearly constant in percentage throughout the school life, but that it was also the condition of health, and withal enjoyed the highest acuity of vision and the greatest freedom from pain.

Second. That myopia, or near-sight, commencing in the primary classes with a low percentage (4.27 per cent.), steadily increases as the pupils pass to the highest grade in our public school system; that the percentage of increase is very much lower in the schools of Philadelphia than in the schools of Europe; that the myopic eye presents a higher percentage of disease than eyes with emmetropic or hypermetropic refraction; that even in *myopic* eyes the percentage of disease is much higher when astigmatism is also present.

Third. That hypermetropic eyes are more numerous than both myopic and emmetropic combined; that, next to myopic astigmatism, distinct lesions are most prevalent in eyes with hypermetropic astigmatism; that the increase in myopia is from eyes with already existing anomalies of refraction,—usually hypermetropic astigmatism,—since it was shown that in hypermetropic, next to myopic astigmatism, was exhibited the highest percentage of disease, which also manifested itself in pathological changes similar to, or identical with, those usually regarded as characteristic of myopia.

This conclusion is strengthened by the fact that such change has taken place under direct observation. It is by no means necessary that the distending eyeball should first pass through emmetropia. In several instances I have had the opportunity of witnessing the gradual change from hypermetropic astigmatism to myopic astigmatism, the meridian of greatest curvature being maintained. Four of these cases were published in the *American Journal of the Medical Sciences*, October, 1880. In one of these published cases a high degree of simple hypermetropic astigmatism passed through mixed to simple myopic astigmatism. Since the date of publication, the left eye has continued to distend, until at the present writing it presents compound myopic astigmatism.

Fourth. That, while there is an evident and close relation between the increase of myopia and the school life, nevertheless, having the preceding conclusions in view, *the educational methods are responsible to only a limited degree.*

This conclusion is supported by the fact so strongly demonstrated in this report, namely, the very obvious relation between the errors of refraction and the diseased conditions of the *fundus oculi*, which shows beyond dispute that the fault is not, primarily, in the system of education, however faulty this may be in many respects, but depends upon the defects which existed in the eye itself at the beginning of the school life. The conclusion, therefore, may be formulated as follows:

That, *given an emmetropic or normal eye, the probabilities are that no harm will come to it from the educational process.* On the other hand, *given an eye with an anomaly of refraction, especially astigmatism, the probabilities are, other things being equal, that the educational process will be fraught with pain and danger to the eye.*

Therefore, that before entering school the possible existence of defective vision should be excluded.

Fifth. That the probability of harm resulting from the school life diminishes with every added year of age, in all states of refraction.

This conclusion finds strong support in the condition of even the emmetropic eyes in the primary schools, as compared with those in the higher classes, as is graphically set forth in Table VI.

Therefore, that our children are placed at school at a too tender age.

Sixth. That, in view of the facts herein set forth, the great importance of proper hygienic surroundings and a wisely chosen and arranged curriculum of study is more than ever manifest.

In arranging the course of study, the principle to be kept in mind is the avoidance of protracted use of the eyes at a near point,—*e.g.*, in reading, writing, or drawing.

1630 Walnut Street, Philadelphia, July 12, 1881.

THE EFFECTS OF THE PROLONGED USE OF ALCOHOL ON THE VISCERA, NERVOUS SYSTEM, AND ORGANS OF SPECIAL SENSE.

Read before the Philadelphia County Medical Society, May 18, 1881,

BY WILLIAM PEPPER, M.D., LL.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

I SHALL limit myself, in the informal and practical remarks I wish to make this evening, to the effects of the prolonged use of alcohol in ordinary and moderate quantities, and shall not dwell on the effects of its habitual intemperate use. As to the latter, there can be no doubt as to the long list of grave lesions produced, involving the nervous centres, the serous and mucous membranes, the glandular organs, etc. Those who indulge in such abuse of alcohol are often of the lower classes, and are much exposed to the effects of other injurious influences, and of reckless habits of living. They often get syphilis; and it is a matter for careful consideration in each case how far the lesions are the result of the alcohol, and how far they may be due to other causes. Passing from these graver lesions, I will try to state in a brief and practical way the results of my own clinical observation as to the effects of the prolonged use of alcohol in moderate quantities. It seems to me, in the first place, that we must admit that there is a certain amount of alcohol that can be used daily by a healthy individual as a part of his regular diet, and which will be thoroughly appropriated and consumed in the chemical changes incident to nutrition. But, while I am in no sense an advocate of total abstinence, I must state that the more closely I watch the effects of the regular moderate use of alcohol, the more convinced do I become that the above physiological quantity, as it may be called, is a very small one, and, further, that it requires to be taken with certain definite regard as to time, quality, and degree of dilution. I do not take into account the exceptional individuals who are able to consume with apparent impunity a considerable daily ration of alcohol; but I am sure I speak for all ordinary persons when I accept the daily limit of from one to two ounces of alcohol, as laid down by Parkes and other writers. This means two or three ounces of whisky or brandy; six to ten ounces of wine, according to the kind and strength; and twelve to sixteen ounces of beer. I do not know of any accurate estimation of the amount of alcohol in the beverages sold ordinarily in our large cities, but my suspicion is that they contain an undue proportion of alcohol. Certainly the above quantities represent what I have been led to regard as the full physiological limit for the vast majority of persons. Again, it is essential that this alcohol be taken very freely diluted. My belief is that, to avoid undue stimulation of the gastric mucous membrane, the beverage should not contain more than six or ten per cent. of alcohol. Further, I am of the opinion that alcohol should be taken only at meal-times, so that even in this dilute form it shall not come in contact with the exposed mucous membrane. It seems to me, then, that we may concede that most persons may take with impunity two or three tablespoonfuls of whisky in a tumblerful of water, or four or five ounces of light sherry diluted with an equal amount of water, or eight or ten ounces of claret, daily, with the principal meal. I do not believe such use of alcohol will, in healthy subjects, cause any injurious effects on the viscera, nervous system, or organs of special sense.

It is of course understood that at the same time an ordinary amount of food and drink is consumed; but it should be remembered that with many persons a most fruitful cause of dyspepsia is the use of too much liquid at meal-times. If the alcohol be taken sufficiently diluted, it results either that a very small amount is taken or that more liquid is used than is wholesome. I have very often had occasion to observe that the regular use of more than a minimum amount of alcohol gradually led in this way to the development of a troublesome form of indigestion, with secondary derangements of nutrition. Still more is this the case if alcohol be taken in a more concentrated form, or on an empty stomach between meals. There is then a distinct tendency to the production of subacute gastritic dyspepsia, not infrequently associated with duodeno-hepatic catarrh. The degree of susceptibility varies so greatly in different individuals that the tendency to these mucous catarrhs should never be lost sight of. They are not trivial, either in the symptoms produced or in the organic lesions to which they may ultimately lead.

We are all familiar with the reflex disturbances of the action of the heart and of the cerebral circulation, and with the faulty digestion and impaired assimilation that sap the vigor of the system. Such irritation, slight though it be, will, in susceptible subjects, if allowed to continue, set up very slow changes in the gastric follicles, in the submucous connective tissue, in the sheaths of the nervous filaments, together with slight catarrhal changes of the mucous membrane of the intestine and biliary ducts. This, then, constitutes one of the chief dangers that I am in the habit of meeting with from the regular use of alcohol; and in persons whose mucous membranes are thus sensitive (and in this country at least their number is very great), alcohol should either be avoided altogether or taken absolutely and exclusively in the very small amounts I have indicated, very freely diluted, and only at meal-times.

Closely associated with the above danger is the tendency of alcohol to develop any latent gouty diathesis. I have long been convinced of the existence of a vast amount of suppressed, irregular, undeveloped, or latent gout in our American communities. It expresses itself by functional derangements, by a difficulty or inability to appropriate and thoroughly work up a proper amount of certain nutritive materials, and by a tendency to certain slow and obstinate tissue-degenerations. Sometimes nitrogenous substances are badly accepted; in other cases the starches or fats disagree most; but in nearly all alcohol is badly borne. It is very easy in such persons to call into action the morbid processes that are favored by the existence of this diathesis. If alcohol be taken by them in any considerable amount (though far within the limits of its intemperate use), or in such a manner as to interfere with digestion, or if in addition to the alcohol—which has a certain value as a quasi-nutrient—a full amount of food be taken without corresponding increase in muscular and mental exertion, the equilibrium is disturbed, imperfect assimilation and defective elimination result, and plethora, congestive states of the nervous centres and of the great glands, with subsequent organic tissue-changes of gouty character, ensue. These effects may require many years for their development if the departure from normal nutrition and the degree of activity of the gouty diathesis are slight. But I meet with too many patients in whom nervous symptoms, circulatory disturbances, or derangements of the functions of the liver, kidneys, or alimentary canal are traceable to a gouty diathesis called into activity by the prolonged use of moderate amounts of alcohol, not to feel forced to call attention to this as one of its prominent dangers. I would not be understood, of course, as implying that the very small daily amount of alcohol which I can feel warranted by clinical experience in regarding as physiological or proper does very often lead directly to such serious results. But it may do so in those who have undue irritability of the gastric mucous membrane, or a strong gouty diathesis. And, in general, I am trying to look at the matter from the stand-point of such hygienic regimen as tends to the maintenance of absolute health, the gradual extinction of inherited morbid tendencies, and the attainment of the greatest longevity, rather than from that of demonstrable serious injury directly traceable to the action of a single agent.

SYMPTOMS AND TREATMENT OF ALCOHOLISM.

Read before the Philadelphia County Medical Society, May 18, 1881,

BY JAS. H. HUTCHINSON, M.D.,

One of the Attending Physicans to the Pennsylvania Hospital.

THE consideration of that portion of the general subject of alcohol in its medical relations which has been allotted to me—viz., "The Symptoms and Treatment of Alcoholic Poisoning, Acute and Chronic"—opens up so extensive a field for discussion that it would be scarcely possible to traverse it satisfactorily, even if a whole evening had been assigned to me for that purpose. Within the brief limits to which it is necessary to confine myself, it will be possible to take a general view of it only.

The symptoms of alcoholic poisoning will vary, of course, with the amount and kind of liquor consumed, the length of time during which its excessive use has been continued, and the age and temperament of the patient. It will be convenient, therefore, to consider them under the following heads:

a. Drunkenness.

b. Acute poisoning by (large quantities of) alcohol.

c. Mania a potu.
d. Delirium tremens.
e. Chronic alcoholism (proper).
f. Dipsomania.

It would scarcely be necessary, even to an unprofessional audience, to enter upon a full description of the symptoms ordinarily presented in drunkenness. The bloated face and reeling gait of the drunkard are, unfortunately, too often seen on our thoroughfares to make any such description necessary. Moreover, drunkenness, as such, rarely comes under the notice of the physician, except in those cases where it presents points of resemblance to apoplexy. The differential diagnosis between these two conditions is sometimes difficult. Flint says the former may generally be distinguished from the latter by the odor of the breath and vomit, by the absence of stertorous respiration, by the character of the pulse, which is usually feeble and soft and increased in frequency,—not diminished in frequency and hard, as is usual in apoplexy, —by dilatation of the pupils, and, generally, by the possibility of rousing the patient sufficiently to exhibit some of the manifestations of drunkenness in the manner of speaking. But these symptoms, while reliable in many cases, will mislead in others. For the respiration is occasionally stertorous and the pupils are sometimes contracted in drunkenness, and the odor of the breath and vomit shows simply that the patient has been drinking, not that his condition is wholly due to alcohol. In proof of this assertion it is sufficient to refer to a case recorded by Hughlings Jackson, in which the alcohol impregnated not only the breath, but the urine also, and in which the patient was left to "sleep it off." He died, however, and at the autopsy a clot was found covering the whole of one hemisphere.*

In acute poisoning by alcohol, when the amount taken is very large, the preliminary stage of excitement seen in ordinary drunkenness is wholly wanting, and the patient drops down instantly insensible, as in a case reported by Dr. Golding Bird,† in which a man drank eight ounces of alcohol. The principal symptoms are profound coma, general anæsthesia, coldness of the surface, which is often covered with a profuse sweat, often cyanosis of the face, stertorous respiration, feebleness and generally excessive frequency of the pulse, and dilatation of the pupils, which are insensible to the light. Occasionally, even in cases which eventually recover, the pulse cannot be felt at all, and this pulselessness may continue for some time. Sometimes the effects produced resemble those of an irritant poison. Thus, the mucous membrane of the mouth and throat may show a whitish discoloration, as in poisoning by acids, and there may be vomiting of blood and the passage of thin, slimy, or bloody stools.‡ In other cases convulsions may precede insensibility, or alternate with periods of delirium for some time before the supervention of coma.

In regard to the condition of the pupils in the coma produced by an excessive dose of alcohol, some difference of opinion exists among authors. Dr. Ogston, who examined twenty-six cases with reference to this point, found that they were dilated in twenty and contracted in six. It is probable that the first effect of alcohol is to contract the pupils, and the secondary to dilate them. Thus, in animals narcotized by alcohol, in whom the pupils were dilated, a fresh dose always caused their temporary contraction. They are almost always dilated in cases in which stertorous respiration is present, and therefore dilatation indicates greater danger to the patient than contraction.§

In cases where the quantity taken is not so large, the symptoms are, of course, not so serious, and may consist of headache, weakness, sleepiness with inability to sleep, diplopia, restlessness, and the like.

The coma in the severe forms may last for several days, and the patient gradually sink, or death may take place within a few hours; or, on the other hand, the patient may by degrees regain his consciousness and finally recover, or else pass into a condition resembling that of ordinary delirium tremens. The prognosis, however, should be guarded in these cases, as a period of seeming health occasionally intervenes between the symptoms above detailed and death. It may be added that diabetes is produced in animals by excessive doses of alcohol.

In proposing to give the name mania a potu to a condition which differs essentially from delirium tremens, I am, of course,

* Quoted by Dr. H. C. Wood in "A Treatise on Therapeutics," Philadelphia, 1874.
† Lancet, October, 1839. p. 166.
‡ Boehm, Ziemssen's Cyclopædia, vol. xvii.
§ Woodman and Tidy, London, 1877.

aware that I place myself at variance with many excellent observers who hold that the two terms are synonymous. But it is convenient to have a name for those outbreaks of maniacal fury which are occasionally caused by excesses in alcohol, and the symptoms of which present a closer resemblance in the main to those of insanity than to those of delirium tremens. These attacks of insanity most commonly occur in drinkers with hereditary predisposition to mental disease, but are by no means confined to them. I have myself known of cases in which no such tendency could be made out. The quantity of alcohol necessary to produce the mania varies considerably with the individual, and in some persons is exceedingly small. In a few instances which have come under my observation a single glass of whisky has been sufficient to produce it, but it has then been of very short duration, while, when it is the result of long-continued excesses, its duration is much more prolonged. In the latter case the patient may have similar delusions to those presented in delirium tremens, but he is usually more violent in his manner, and does not generally show the same degree of cowardice and timidity.

It seems to me important to recognize this form of insanity, and its cause, as it demands a special treatment, under which it generally leads to recovery.

Only a few years ago delirium tremens was universally regarded as the result of the abrupt withdrawal of stimulus after it had been used for some time to excess. But, while the influence of this cause in the production of the disease in a large number of cases is still maintained by many observers of the highest authority, there are others, and it is probable that they are in the majority, who hold that it is always an effect of the direct action of alcohol upon the brain. After a careful consideration of much that has been written upon the subject, I find myself compelled to adhere to the opinion which I have formed from my own observation, that delirium tremens may arise from either of these two causes, and that the symptoms are slightly different in the two cases. That delirium tremens may sometimes occur as the consequence of the sudden cessation of the use of alcohol is frequently witnessed in the surgical wards of any general hospital. I have repeatedly seen, for instance, in the cells of the Pennsylvania Hospital, men suffering from the disease whose previous health had been good, but whose habits of free stimulation had been interrupted by the accident for which they had been admitted, and which in many cases was of so trivial a character that it would be unreasonable to attribute to shock any share in the production of their delirium, and I have seen others, presenting at first the same symptoms, in whom the outbreak of the disease was prevented by the administration of a moderate amount of whisky. The same thing may be observed in the medical wards, although not so frequently. During my last term of service at the hospital, three patients addicted to the excessive use of alcohol were admitted with erysipelas of moderate severity. They were all allowed a small quantity of whisky, much less than they had been accustomed to consume when in health, and much less than was given to some other patients who were suffering from the same disease in a much more severe form, but who were temperate in their habits. In all of these cases, as soon as convalescence was established, delirium tremens occurred.

Delirium tremens in its mildest form is popularly known as "the horrors." Its most characteristic symptoms then are tremor, restlessness, sleeplessness, and a disturbed, anxious expression of the countenance. This tremor, Anstie says, first begins in the legs, but usually escapes notice, because more difficult to detect there than in other parts. It is readily seen in the trembling of the tongue when protruded, and of the hands when extended. In this stage it is generally controllable by a strong effort of the will, and is usually worse in the morning. It is relieved temporarily by food or alcohol. With these symptoms there is also a feeble and frequent pulse, contraction of the pupils, an inability to concentrate the mind upon any subject, and depression of spirits. The patient becomes vacillating, suspicious, quarrelsome, and cowardly. If the attack has followed a recent debauch, there are evidences of gastric disturbance in the presence of furred tongue, thirst, anorexia, etc. Occasionally certain cerebral symptoms present themselves, such as buzzing, whistling, or roaring sounds in the ears. Muscæ volitantes and flashes of light occur just as the patient is dropping off to sleep. Sleep, when it comes, is disturbed by frightful dreams. According to Magnan,

the sense of the perception of colors is less acute in this condition.

The condition above described frequently ends in recovery, especially if properly treated, but in many cases glides imperceptibly into what may be described as the second stage of delirium tremens.

Second Stage.—All the symptoms of the first stage are exaggerated in this, and new ones are added. Among the most characteristic of these are hallucinations, which occur, at first, during the night only, and may often be dispelled if the patient can be amused. They are almost invariably of a disagreeable character, and when not positively painful suggest painful ideas, as in a case referred to by Magnan, in which the patient spoke of cascades which he heard roaring, and of chalets which he saw filled with people dancing and singing; but the cascades impelled him, he said, to drown himself, and the gay occupants of the chalets wished to assassinate him. The delusions generally have some relation with the occupation of the individual, or with the dominant subject of interest of the moment. Sometimes the scene of the last debauch is rehearsed, or a quarrel which took place there is renewed in imagination.*

The hallucinations of the sense of sight are most frequent. The patient sees about him devils, snakes, rats, mice, and vermin of all kinds, from which he vainly attempts to escape. Those of the sense of hearing come next in frequency. In addition to the noises mentioned as occurring in the first stage, the sufferer hears the sounds of funeral bells, and of singing and other music, generally of a mournful character. Cries and tumultuous voices torture him, even though he closes his ears against them. Perversions of the senses of smell and taste, although less frequent than those of sight and hearing, nevertheless occur, and contribute their quota towards the distress of the patient, who may be harrowed by disagreeable smells, or believe that his food is tainted, or that it contains some poisonous substance. The general sensibility also usually presents some evidence of derangement. The most common perversion of sensibility is the feeling of ants or other insects crawling over the body or under the skin, and the efforts which the patient makes to detach them are often sufficiently ludicrous. At other times he believes himself to be enclosed in a net, and spends his time in fruitless efforts to disengage himself from it. The timidity, anxiety, and fear of the first stage are intensified in this, the patient believing himself to be pursued by policemen, or by enemies who desire to take his life. In his attempts to escape from his imaginary foes he may commit acts of violence which he believes are necessary to protect his own life. In some instances, however, without having any such delusion, he is disposed to fight those around him, and to be mischievous and destructive.

Tremor, it is said, may occasionally be wanting, but it is then replaced by great restlessness. When it affects only a few muscles it does not indicate nearly so much danger, even when intense, as when all the muscles of the body are involved, especially if the tremor persists during sleep and is accompanied by subsultus tendinum, no matter how little marked it may be.† The fact that the skin is generally bathed in a clammy sweat, and feels cool to the hand, has given rise to the impression that the disease is rarely attended with fever; but this has been shown to be an error by Magnan, who has described a febrile form of the disease, and who says that in this form the temperature may rise as high as 105.8° F. Bristowe also refers to cases in which the temperature rose to 109° F. A temperature above 105° F., especially if it has risen suddenly to this point, indicates great danger to the patient. The pulse is frequent and feeble, often running as high as 140. It is dicrotic, and sometimes small and thready, sometimes soft and voluminous. The pupils are sometimes contracted and sometimes dilated, but are rarely, according to Gerhard, much contracted, except in the cases treated by large doses of opium. There is always complete anorexia, and very often there are other symptoms of a disordered digestion, such as vomiting and constipation or diarrhœa. The tongue may be covered with a thick whitish coating, or be brown, dry, and fissured, or clean, red, and glazed. The patient is constantly talking, but his utterance is usually thick and indistinct. Convulsions occasionally occur, and may leave behind them paralysis of some form, or the patient may pass from them into fatal coma. Sleep rarely comes

* Magnan.

† Ibid.

to the sufferer, and when it does occur it is not always followed, as is popularly supposed, by recovery.

This disease is in some cases difficult to distinguish from meningitis. Flint thinks a diagnosis may be generally made by attention to the following symptoms: the increase of the phosphates in the urine in meningitis and their diminution in delirium tremens, and the presence of intense headache and intolerance of light in the former. It must be remembered, however, that meningitis may be caused by excesses in alcohol, and sometimes occurs in the course of an attack of delirium tremens.

In the third and final stage the symptoms increase in severity, one hallucination succeeds another with great rapidity, muttering delirium comes on, the sweating becomes colliquative and the depression extreme, until the patient sinks into a comatose condition, which usually terminates in death.

Chronic Alcoholism.—The effects of the long-continued use of alcohol other than those just referred to are shown not less in the mental and moral debasement of the individual than in the deterioration of his physical health. The faculties of his mind are impaired just in proportion as he gives himself over to his indulgence, and this impairment shows itself especially in the weakening of memory and of judgment and in a diminution of quickness of comprehension and of power of concentration. He grows in many cases untruthful and cunning, or cowardly and apathetic, ceasing to care or to provide for his family. He is liable to suffer from depression of spirits, and may have suicidal tendencies. In this unhappy frame of mind he is unable to resist the temptation to renew his excesses, as he finds in them a temporary relief from his feeling of utter wretchedness. The appearance of the common sot is also characteristic: his face wears a dull, heavy expression, his eyes are congested and watery, and his muscles soft and flabby. Occasionally he sinks into a condition of positive dementia, from which it may be difficult or impossible to rouse him, or he may become the victim of general paralysis.

With the above symptoms there are also abundant evidences of physical derangement. Not to take up the time of the Society in detailing the various symptoms which arise from the fibrotic degeneration of the liver and kidneys, or from chronic catarrh of the stomach, the patient may suffer from constant tremor, feebleness, and shooting pains in the limbs, from pricking sensations of the skin, from numbness or tingling, from anæsthesia or hyperæsthesia, and from abnormal sensations of heat and cold.

I have included *Dipsomania* among the effects of the excessive use of alcohol, because the uncontrollable appetite which it indicates is unquestionably often the consequence of previous excesses; but it is not necessary to consider it fully in this paper, as the symptoms it presents are very much the same as those just detailed as occurring in chronic alcoholism.

Treatment.—In acute poisoning by large doses of alcohol the principal indication is at once to empty the stomach. This may often be accomplished by the administration of emetics, but in many cases it will be necessary to resort to the stomach-pump. If these means fail in restoring the patient to consciousness, recourse should be had to the usual mechanical methods for arousing a narcotized patient, such as alternate douches of hot and cold water, electricity, and counter-irritants.

It will be convenient for the sake of brevity to discuss the treatment of mania a potu and delirium tremens under one head.

In considering this question the advisability of withholding or giving alcoholic stimulus at once arises. A few years ago it was always given; now it is rarely allowed, and it is probable that it is not often, if ever, necessary. It may occasionally be administered with advantage when there is alarming prostration, but under other circumstances it is calculated to do harm. I am therefore decidedly disposed to agree with those who withhold it entirely, rather than with those who prescribe it indiscriminately. Opium is a drug which should also be given only when the indications for its use are strongly presented. When given in large doses, as it was in former years, in the hope of producing sleep, it was often the cause of coma or convulsions.

If the attack has come on shortly after a debauch, an emetic may sometimes be of service, but its tendency to depress should be remembered, and it should therefore be given to young and robust patients

only. Under similar circumstances, if there is much evidence of gastric derangement, I have sometimes found a mild mercurial purge of service. More important than the medicinal treatment of the disease is the administration of food to the patient in proper amount and of proper kind. Attacks may be often arrested by this means alone. I shall therefore consider it first. My friend Dr. Robert P. Harris, whose long experience in the treatment of alcoholism at the Franklin Reformatory Home gives great weight to his opinion, tells me that it is an essential part of his treatment, and that he has often given as much as two quarts of milk and the essence of five pounds of beef daily in the incipient stage of delirium tremens, with the effect of preventing its further development. These quantities are, of course, larger than is often necessary, and, indeed, larger than will usually be borne. Milk is to be preferred to all other forms of nutriment, and will be generally retained if given in combination with lime-water. If the stomach rejects it, however, as it will sometimes do, beef-tea will be found to be the best substitute. When this is also vomited, it will be necessary to have recourse to nutrient enemata. To relieve his thirst the patient may be allowed to suck small pieces of ice, or to take moderate draughts of water, since large draughts are very apt to provoke vomiting and retching. Frequently the aërated waters are very acceptable to the stomach.

At the Pennsylvania Hospital we are accustomed to give our patients the bromide of potassium in doses of gr. xx–xxx every two or three hours, with a dose of chloral gr. xx, repeated, if necessary, at night, and rarely any other medicines. Occasionally a hypodermic injection of morphia is administered; but this does not form an essential part of the treatment. During convalescence a tonic is given,—sometimes quinine, and sometimes one of the tonic tinctures; but the former is preferable. Dr. Harris uses the bromide of sodium instead of the bromide of potassium, and does not prescribe chloral, but otherwise his treatment is essentially the same as ours.

Other drugs which have been given in the treatment of delirium tremens are digitalis, valerian, assafœtida, Hoffmann's anodyne, camphor, and chloroform by inhalation. The latter is a dangerous remedy, and of the other remedies digitalis alone merits serious consideration. While I should myself hesitate to give it in the large quantities recently recommended, I have seen it do good in moderate doses, not only in the condition pointed out by Fothergill and others, *i.e.*, when the pulse is compressible, rapid, and fluttering,—in fact, when there is evidence of cardiac distention, accompanied by great nervous prostration,—but also when the symptoms indicate the presence of serous effusion in the arachnoid cavity.

Some authors advise that the patient should not be confined in a cell in the early stage of the disease, but should be allowed cheerful society; and others recommend exercise as a means of retarding the development of the disease. But I should hesitate before putting into practice this advice, since rest and quiet have always seemed to me important elements in its treatment, and I have known at least one patient die from heart-clot which was evidently due to the persistent efforts of the patient's friends to make him "*walk off*" an attack. In regard to the use of mechanical means of restraint the same difference of opinion seems to exist between English and American physicians as obtains in the management of insanity. Even if it were possible to place implicit reliance upon the temper and self-control of an attendant, the plan of confining a patient in bed by means of anklets and gloves, with the addition, in very violent cases, of a strap across the chest, possesses so many advantages as a means of restraint over any other plan that I do not see how any one can hesitate in giving it the preference.

I have had a table carefully drawn up by my clinical assistant, Dr. Joseph M. Fox, which shows the results of treatment in this disease at the Pennsylvania Hospital during the twenty-three years which have elapsed since I first became connected with it. During the greater part of this time it was usual to treat the disease with large quantities of stimulus, and with more or less opium. Exactly when the change to our present plan of treatment took place I am not able to say, but it was made some time during the last ten years. It will therefore not be unfair to compare the results of treatment obtained during this period of time with those obtained during

the previous thirteen years. From the year 1858 to the year 1870 inclusive, 907 cases of alcoholism of varying severity were admitted to the hospital, and of these 73 ended in death, or about 8 per cent. Since 1870, 577 cases have been received, and of this number 14 have terminated fatally, or about 2.4 per cent. I find also that the average duration of treatment in the cases in which recovery took place has also undergone a notable diminution: thus, in the first period of time it was 7½ days; in the second, only 5½. On the other hand, the duration of the fatal cases was shorter during the second period of time than during the first. In fact, in many of them death occurred so soon after admission that the patient may fairly be assumed to have been beyond the reach of remedies when admitted.

These figures speak so loudly in approval of our present plan of treatment that comment upon them is unnecessary. Under the whisky treatment, too, it was not uncommon for a patient to become violent after his admission, even if he had not previously been so. Under the present plan this rarely happens.

The treatment of chronic alcoholism may be disposed of in a few words. It consists principally in the withdrawal of all stimulus and the substitution for it of tonics, such as quinine, cod-liver oil, and iron, and in the administration of nutritious food in a concentrated form. Of course, indications furnished by the various diseases which alcohol engenders should be met by the appropriate remedy. Dr. Marcet speaks highly of the oxide of zinc as a remedy in this condition, claiming for it not only the power of relieving present symptoms, but also that of preventing outbreaks of delirium tremens. I have no experience with it in the treatment of this condition, and will therefore only quote what Golding Bird has said of it. "It has," he says, "a specific influence on the nervous system in about the same manner as iron on the blood, especially in those cases which are unattended by any organic disease." The bromides may also be of service here; but their tendency to produce derangement of the digestive tract and anæmia, when long continued, should always be borne in mind. Other remedies which may occasionally be given with advantage are strychnine, camphor, and sumbul root.

	Whole number treated.	Died.	Cured.	Relieved.	Eloped.	Discharged by request.	Average number of days in hospital of cases cured.	Average number of days in hospital of fatal cases.	Proportion of fatal cases.	Percentage of deaths.

ARE THE ADDUCTOR FIBRES OF THE INFERIOR LARYNGEAL NERVE MORE APT THAN THE ABDUCTOR FIBRES TO RECOVER FROM DISEASE OR INJURY INVOLVING THE ROOTS OR TRUNKS OF THE MOTOR NERVES OF THE LARYNX?

BY LOUIS ELSBERG, M.D.,

Professor of Laryngology and Diseases of the Throat in the Medical Department of the University of New York, Lecturer in Dartmouth Medical College, etc.

THE leading article of the July issue of the *Archives of Laryngology* is entitled "Clinical remarks on the proclivity of the abductor fibres of the recurrent laryngeal nerve to become affected sooner than the adductor fibres, or even exclusively, in cases of undoubted central or peripheral injury or disease of the roots or trunks of the pneumogastric, spinal accessory, or recurrent nerves. By Felix Semon, M.D., M.R.C.P. London." I have had occasion to read that essay very carefully, and can from my own clinical observations bear ample testimony to the correctness of the positions taken. The very curious and important fact, ably discussed by Dr. Semon, though not new or entirely unrecognized, is now more prominently than it has hitherto been pressed upon the attention of laryngologists. A rare "companion" fact, the publication of which is particu-

larly timely in view of the discussion to take place at the coming International Congress, is embodied in the question which heads this communication. I answer the question in the affirmative. So far as I know, it has not before been alluded to.

A case illustrating the point is the following. C. B. C., when 15 years old, belonged to a base-ball club at school, in which he took much interest. In May, 1879, while practising for a match game, on throwing a ball with all his strength, he suddenly felt a sharp pain in the region of the thyroid cartilage. During some days thereafter, he also noticed, in playing hard, a sensation like an electric shock down the left arm. Twelve days after the first sensation the match game came off, and while he was excited, hot, and thirsty he took large quantities of iced water and ice-cream, which shocked him considerably. Soon after he got violent hiccough, and became unable to swallow and to speak. Nevertheless, he managed for nine days to get some food, entirely liquid, down by a swallow or two at a time. Then feeding with the stomach-tube had to begin, which was continued for three weeks. His left extremities, especially the arm and hand, had become weak, and he was deaf in the left ear. Gradually he improved; but just as deglutition and phonation became better, inspiration gradually became worse, so that after several dyspnœic spasms (one in July and one in August) his breathing six months later (loud, stridulous, and only six or seven times per minute, February 1, 1880) necessitated tracheotomy. Many very interesting features of this case (such as that from the first the sensibility of the larynx and pharynx was greatly diminished, and that gradually hyperæsthesia involved the left, first upper and then lower, extremity, etc., etc.) I pass over, as the case will be published hereafter in detail. He was seen by many physicians, but the gentleman who mainly had and still has him under exclusive care is Dr. W. E. Ford, of Utica. Dr. Hutchings, of Utica, performed the tracheotomy.

In this case there was at one time, on account of complete paralysis of both the inferior and superior laryngeal nerves, so-called "cadaveric position" of the vocal band. It may be worth while to say that this designation is sometimes used incorrectly. Very strictly, of course, it can never be applied in the living subject; and even in the case of paralysis of the recurrent nerves—to describe which condition on account of graphicness and brevity Ziemssen introduced it—we must not quite lose sight of innervation by the superior laryngeal; but in paralytic conditions of the adductors, with perhaps sluggishness of abduction, as in hysterical aphonia, in which I have known it to be used, it is entirely incorrect. In every case in which the vocal bands cannot be brought into proper apposition, there is, in phonation, straining, coughing, etc., unavoidable *leakage* of air, a term I have long used technically in accounting for the imperfect manner in which these processes are performed.

In the case of young C. B. C., gradually the integrity of the two laryngeal nerves became to a considerable extent re-established; but the adductor muscles regained power so much more rapidly than their antagonists that at one time there was almost complete "phonatory position" of the vocal band, exactly as though the abductor alone had been paralyzed. Unfortunately, events happened which interfered with continued recovery. During relapse or increased paretic condition of all the nerves affected, the abnormal intralaryngeal equipoise was re-established, and an approach to the "cadaveric position" of the vocal band was again brought about; while since then, with renewed improvement of all the other symptoms, the position which the vocal band has assumed is again nearer the median line. The clearness of the latter demonstration of the affirmative of the question heading this communication was surprising to me.

Cases in which recovery after complete paralysis of the laryngeal muscles can be observed are very rare, but they do occur. It has been my good fortune to have seen certainly three, perhaps four, cases more or less in point; and in all the cases there occurred, with whatever obvious progress towards convalescence there was, for the time being, an increasing inspiratory dyspnœa from more or less "phonatory position" of the vocal bands, showing continuing inaction of the abductors or preponderating action of the adductors. In no case during the course of recovery has isolated or preponderating restoration of abduction taken place before the restoration of adduction.

I cannot but believe that similar cases must have occurred in the experience of

other observers, although the question involved may not have specially struck them. I have not carefully enough examined into the literature to state that no such cases have been reported. For instance, in a case to which Mackenzie* refers, there seems to have been a partial recovery illustrating the point. It was the case, reported by Dr. Hughlings Jackson,† of a man who, with the symptoms of nervous lesion and paralysis of a vocal band, had lost his voice, but could breathe. He appears to have improved, and Mackenzie reports in a foot-note that he has more lately found that, whilst some power has been recovered in the adductor, the right abductor has become paralyzed. Owing to this condition, the patient now suffers from slight though constant stridor.

I shall not attempt here to discuss the cause, or the physiological and other relations involved. I only desire to state the fact, and to elicit the publication of cases observed by others.

TRANSLATIONS.

NATURE AND PATHOGENESIS OF THE VISCERAL LESIONS WHICH FOLLOW PROGRESSIVE ENDARTERITIS OBLITERANS (DYSTROPHIC SCLEROSIS).—Dr. H. Martin (*Revue de Médecine*, 1881, No. 5, p. 391), at the conclusion of a long and exhaustive paper on this subject, gives the following *résumé*.

1. The internal coat of most of the arterioles of the organism is exposed during almost the whole of its existence to causes of irritation which tend to cause inflammation, narrowing, and consequently a proportionate diminution in the quantity of blood in circulation.

2. This progressive obliterative endarteritis begins in the first years of existence, and localizes itself, particularly in the case of young children, in certain nutritive vessels in the first portion of the aorta, whence the appearance of small patches of atheroma in this locality. Later it invades a large number of arterioles, localizing itself, however, by preference in those organs whose circulation and activities are greatest.

3. The progressive diminution of material carried to such a viscus gives rise at once to both atrophy of the important or functional elements, and proportional development of connective tissue. This sclerosis begins at as remote a point as possible from the diseased arterial trunks, where the nutrition is most insufficient. It is not preceded by lesions of the capillaries in this neighborhood. Finally the active cells in the vicinity of which it appears seem healthy and non-inflamed during the initial period and up to the time when the sclerosed tissue has taken on a notable development. "Nothing," says Dr. Martin, "proves (so it seems to us) that this is the consequence of inflammatory irritation." It is for this reason that the affection has been designated *dystrophic sclerosis*.

4. This knowledge regarding progressive endarteritis accounts for a large variety of visceral scleroses; it shows, also, the bond which, from a pathogenetic point of view, unites a certain number of scleroses. It shows, for instance, why cirrhosis should begin in such an organ rather than in such another; why, for example, that lesion of the heart which is considered consecutive to interstitial nephritis may, on the contrary, precede this nephritis; why endarteritis may localize itself primarily, or after other similar localizations (aorta, heart, etc.), in the nutritive arterioles of the posterior regions of the cord, and may there give rise to the lesion and the symptoms of ataxy; why, finally, there exists such remarkable similarity of feature between affections apparently so different.

5. Progressive endarteritis may evolve under the acute form, particularly in certain infectious diseases (diphtheria, typhoid fever). It then gives rise to rapid circulatory disturbances which may themselves alone cause death, when the organ affected is one which fills an important function,—the heart, for example.

6. The irritating particles which circulate in the blood, particularly in certain individuals (alcohol-drinkers, gouty, lead-poisoned persons), can only exaggerate and hasten the evolution of progressive chronic endarteritis. As for acute endarteritis in infectious diseases, modern theories of parasitism fit in admirably with this conception and explain its evolution naturally.

7. From a histological point of view, the proliferative lesion often begins in the endarteritis itself,—rests there localized or spreads beyond it. Sometimes, however,

it predominates beyond the internal elastic coating, dissociating then this coat; and in this case we must grasp the morbid process from its first phases to comprehend the point of departure of its localization and evolution.

The Effect of Long-Continued Minute Doses of Mercury on Animals.—Schlesinger, in a prize essay published in full in the *Archiv für Exp. Path.* (Bd. xiii. S. 352), gives the following conclusions.

Rabbits, and particularly dogs, bear without harm the continuance for a year of small doses of chloride of mercury and sodium. Compared with control animals, however, they show a certain increase in weight, while examination shows a surprising increase in the number of red blood-corpuscles. In spite of this, the urine of these animals shows no change in its ordinary constituents, and no sugar or albumen present at any time.

The animals killed after taking mercury during a shorter or longer period show no disease of any organ. They only show a larger accumulation of fat in those localities where fat is usually found in dogs.

While Keyes's conclusions as to the results of small doses of mercury are thus confirmed up to a certain point, Schlesinger is inclined to doubt the tonic action of mercury thus given; for, of all the favorable effects which we are accustomed to observe after the use of that certainly active tonic, iron, none appeared to be present after the employment of mercury. In those cases where iron acts as a tonic,—that is, where the blood appears to be impoverished of its normal hæmoglobin (*i.e.*, ferruginous contents),—we see going hand in hand with the increase in the number of red blood-corpuscles a rise in the body-temperature, increase in frequency in the pulse, in the body-weight, and in the excretion of urea. In the case of Schlesinger's dogs, increase in the number of blood-corpuscles and in body-weight was not accompanied by any change in the urinary excretion.

The increased number of red blood-corpuscles, together with the greater accumulation of fat, in the animals experimented upon, appears to show that the long-continued use of small doses of mercury, together with sufficient nourishment taken, exercises a repressive influence on the oxidation process to a slight extent. Should these researches be verified, the view must be accepted that by long-continued use of the bichloride of mercury with chloride of sodium the normal disintegration of the red blood-corpuscles is hindered in healthy persons, and, in part, precisely on this account a more considerable accumulation of fat occurs.

It may be supposed, then, that small doses of mercury do not act tonically in syphilitic patients, but that, when not sufficiently large to destroy the syphilitic virus, they leave the tissues entirely unaltered, and at most favor the increase of body-weight by their influence in retarding tissue-change and the disintegration of the red blood-corpuscles.

The following assertion, based upon the researches above mentioned, may be made,—namely, that Keyes's observations are correct, but that the conclusions which he has drawn from them are without foundation.

Case of a Tailed Man.—Max Bartels (*Virchow's Archiv*, Bd. lxxxiii. S. 189) gives an account of another of these curious formations. It occurred in the case of a hearty, well-formed man of 50. When undressed and leaning over, a body the size of a plum, covered with livid red skin, could be seen between the nates. It looked at first glance like a large hemorrhoidal tumor, but on separating the nates it was seen not to be connected in any way with the anus or nates, but to hang freely over it by a narrow cutaneous attachment to the upper end of the sacral notch, just over the point of attachment of the coccyx.

"Having just finished a work on human tails," says the enthusiastic Bartels, "the reader may imagine my agitation when I discovered this appendage, which occupied so undeniably the classical position of a tail. At once the hope was aroused in my mind of adding to the nineteen cases of tailed men thus far observed in Europe a twentieth,—a hope quickly dashed, however, by a further examination. If this appendage were a tail it should be congenital; but the patient asserted that it had only existed five years. However, when extirpated, the tumor had sufficient likeness in structure to pass for one." Bartels includes it under Virchow's classification as a "lipoma fibrosum cutis coccygialis pendulum." He remarks that there was perhaps a larger quantity of hair over the sacral region than is common.

EDITORIAL.

THE MEDICAL REGISTRY LAW.

AT the recent session of the Legislature of Pennsylvania an act was introduced which has now, by the signature of the Governor, become a law of the State, and which is intended to regulate the practice of medicine. It reads as follows.

AN ACT

To Provide for the Registration of all Practitioners of Medicine and Surgery.

SECTION 1. *Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by the authority of the same,* That the prothonotary of each county shall purchase a book of suitable size, to be known as the medical register of the county (if such book has not been purchased already), and shall set apart one full page for the registration of each practitioner, and when any practitioner shall depart this life or remove from the county he shall make a note of the same at the bottom of the page, and shall perform such other duties as are required by this act.

SEC. 2. Every person who shall practise medicine or surgery, or any of the branches of medicine or surgery, for gain, or shall receive or accept for his or her services as a practitioner of medicine or surgery any fee or reward, directly or indirectly, shall be a graduate of a legally chartered medical college or university having authority to confer the degree of doctor of medicine (except as provided for in sec. 5 of this act), and such person shall present to the prothonotary of the county in which he or she resides or sojourns his or her medical diploma, as well as a true copy of the same, including any indorsements thereon, and shall make affidavit before him that the diploma and indorsements are genuine; thereupon the prothonotary shall enter the following in the register, to wit: the name in full of the practitioner, his or her place of nativity, his or her place of residence, the name of the college or university that has conferred the degree of doctor of medicine, the year when such degree was conferred, and in like manner any other degree or degrees that the practitioner may desire to place on record, to all of which the practitioner shall likewise make affidavit before the prothonotary, and the prothonotary shall place the copy of such diploma, including the indorsements, on file in his office for inspection by the public.

SEC. 3. Any person whose medical diploma has been destroyed or lost shall present to the prothonotary of the county in which he or she resides or sojourns a duly certified copy of his or her diploma; but if the same is not obtainable, a statement of this fact, together with the names of the professors whose lectures he or she attended, and the branches of study upon which each professor lectured, to all of which the practitioner shall make affidavit before the prothonotary, after which the practitioner shall be allowed to register in manner and form as indicated in section 2 of this act, and the prothonotary shall place such certified statement on file in his office for inspection by the public.

SEC. 4. Any person who may desire to commence the practice of medicine or surgery in this State after the passage of this act, having a medical diploma issued or purporting to have been issued by any college, university, society, or association in another State or foreign country, shall lay the same before the faculty of one of the medical colleges or universities of this Commonwealth for inspection, and the faculty being satisfied as to the qualifications of the applicant and the genuineness of the diploma shall direct the dean of the faculty to indorse the same, after which such person shall be allowed to register, as required by section 2 of this act.

SEC. 5. Any person who has been in the continuous practice of medicine or surgery in this Commonwealth since one thousand eight hundred and seventy-one without the degree of doctor of medicine shall be allowed to continue such practice, but such person shall, nevertheless, appear before the prothonotary of the county in which he or she resides, and shall present to him a written statement of these facts, to which the practitioner shall make affidavit; thereupon the prothonotary shall enter the following in the register, to wit: the name in full of the practitioner, his or her place of nativity, his or her place of residence, the time of continuous practice in this Commonwealth, and the place or places where such practice was pursued, to all of which the practitioner shall likewise make affidavit, and the prothonotary shall place the certified statement on file in his office for inspection by the public.

SEC. 6. Every practitioner who shall be admitted to registration shall pay to the prothonotary one dollar, which shall be compensation in full for registration, and the prothonotary shall give a receipt for the same.

SEC. 7. Any practitioner who shall present to the faculty of an institution for indorsement, or to a prothonotary, a diploma which has been obtained fraudulently or is in whole or in part a forgery, or shall make affidavit to any false statement to be filed or registered, or shall practise medicine or surgery without conforming to the requirements of this act, or shall otherwise violate or neglect to comply with any of the provisions of this act, shall be deemed guilty of a misdemeanor, and on conviction shall be punished for each and every offence by a fine of one hundred dollars, one-half to be paid to the prosecutor and the other half to be paid to the county, or be imprisoned in the county jail of the proper county for a term not exceeding one year, or both, or either, at the discretion of the court.

SEC. 8. Nothing in this act shall be so constructed as to prevent any physician or surgeon legally qualified to practise medicine or surgery in the State in which he or she resides from practising in this Commonwealth, but any person or persons opening an office or appointing any place where he or she may meet patients or receive calls shall be deemed a sojourner, and shall conform to the requirements of this act.

SEC. 9. This act shall take effect on the first day of June, one thousand eight hundred and eighty-one.

The advantage to the community of such a law as the present has long been obvious, and credit is due to the framers of this act and to those instrumental in having it passed by the Assembly. The fact that an official register of legally qualified practitioners of medicine exists, and can readily be consulted, must alone serve to draw a

line of distinction between the illegal quack and the legally qualified physician which can be appreciated by all. And the severe penalty, pecuniary and personal, which attaches to any infraction of the law should, we hope, tend to make the unauthorized pursuit of medical practice a much more difficult matter than it has been in the past.

The requirements for registration are not onerous,—the moderate fee of one dollar, and the presentation of the diploma with due affirmation of its authenticity, being all that is required, save that a copy of the diploma must be placed on file. He to whom time and inclination are wanting to transcribe his diploma may without difficulty obtain a printed copy. These are, indeed, already issued officially by the University, and will, we doubt not, also be furnished by the other medical colleges.

A weak point in this otherwise admirable law is, it appears to us, the fact that no limit of time is fixed for registry beyond which the penalty may be exacted for non-compliance. The act went into effect on June 1. Are all practitioners who failed to register on that day liable to fine and imprisonment? Hardly, we should think. But, on the other hand, how long are the ignorant, negligent, and criminously inclined to be permitted to neglect registration? Indefinitely? It looks like it. We venture also to wonder how the prothonotary is to know when any practitioner has "departed this life." Must he scan the daily papers for this purpose? But, on the whole, the act is a good one, and fraught, we may hope, with advantage to the dignity and respectability of the profession and the health and safety of the community.

How to Register.—Take diploma and a printed copy thereof, with dates and names filled in, to Dr. S. B. Hoppin, the courteous functionary who has charge of the Medical Register, and whose desk is in the Prothonotary's Office, State-House Row.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

An adjourned conversational meeting was held May 18, to continue the discussion on "Alcohol."

Dr. Pepper read a paper on "The Effects of the Prolonged Use of Alcohol on the Viscera, Nervous System, and Organs of Special Sense" (see p. 686); and Dr. Jas. H. Hutchinson one entitled "The Symptoms and Treatment of Alcoholic Poisoning, Acute and Chronic" (see p. 687).

DISCUSSION ON ALCOHOL (*continued*).

Dr. Jas. Tyson thought that the influence of alcohol as a direct cause of renal disease had been exaggerated by many. This error was pointed out by Dr. Dickinson in the first edition of his book, and confirmed by autopsies. The effect of alcohol upon the kidneys is trifling in comparison with the action of other causes to which drunkards are exposed. The speaker had examined the urine of men accustomed to use large amounts of whisky,—drinking a pint or more daily,—and had found it free from albumen and free from casts: this had occurred over and over again. Nevertheless, there can be no doubt that drunkards are largely subjects of Bright's disease: this, however, is not the direct effect of the alcohol, but is due to the exposure to which they are constantly subjected. Of course the kidneys can be directly affected by large doses of alcohol; but this is comparatively seldom. The explanation is that before the alcohol can reach the kidneys it has to pass the bulwark of the stomach, liver, and, more especially, the lungs, where the oxidation is very rapid: very little is left in the blood which reaches the kidneys. When poisonous doses of alcohol do affect the kidneys, they produce tubal nephritis rather than interstitial, the poison operating more like that of scarlet fever.

Dr. C. B. Nancrede confirmed the observation of the lecturer that the children of the insane are more apt to be especially affected by alcohol. He reported a case of a young man whose father was insane, and whose mother was eccentric and subject to ungovernable attacks of rage. On various occasions a single glass of stimulant had caused vomiting, followed by symptoms of mania, which passed away in a week or ten days. Both father and son presented the identical symptoms at the beginning of their outbreaks.

Dr. W. F. Stewart called attention to the increased action of the heart under the effect of alcohol, as pointed out by Richardson, of London, causing an increase of from 17,000 to 24,000 beats in the twenty-four hours. In health such extra exertion must be unnecessary and injurious. The same authority con-

cludes that the alcohol affects the blood by condensing and contracting the red blood-corpuscles.

Dr. W. R. D. Blackwood said that he had seen many cases of mania and delirium tremens, and was confident that the treatment by opium had been abused. He now relied upon bromides. Moreover, he was confident that both the acute and chronic cases are better without whisky than with it. In preference to all other remedies he held digitalis: where it has failed, it is because it has not been used in sufficiently large doses. He usually gave drachm doses, but had given as much as an ounce of the tincture, repeated every three hours, and kept up for twenty-four hours,—giving in all six or eight doses,—and considered it just as safe in these doses in delirium tremens as in ten- or fifteen-drop doses under ordinary circumstances. His cases now get well without any stimulant better than they did some years ago with stimulants. The patients do not take food readily at first, on account of the gastric catarrh; but it is of great importance to give nourishment during the early stages of delirium tremens, and milk and meat extracts should be given regularly. In conclusion, he insisted that digitalis is safe in the enormous doses mentioned in delirium tremens, and is to be preferred above all other remedies which we possess.

Dr. F. G. Gross asked the preceding speaker if he had tried the infusion of digitalis. It is strange that he had recommended withholding all stimulants, and gave a tincture in half-ounce or ounce doses six or eight times in one day. This represents a considerable amount of alcohol, and as much as is ordinarily given.

Dr. Blackwood said that he had obtained the same effects from the infusion. He did not mean to say that the tincture should always be given in such large doses where smaller ones will answer the purpose, although digitalis is well borne in large doses in delirium tremens.

Dr. R. B. Cruice said that he had treated 1008 cases of alcoholism at the St. Joseph's Hospital during the last six years. The usual treatment is to give a purgative and then capsicum (three grains every hour), which stops the craving for drink and quiets the stomach. He gives a moderate amount of stimulants, depending upon hop tea and capsicum to relieve the restlessness. The food is light,—principally milk, tea, and highly seasoned soups. When there is much vomiting and pain, a small blister is placed over the epigastrium, and in some cases he applies a blister at the back of the neck. As soon as the patient begins to eat, alcohol is stopped entirely. Out of this series of more than a thousand cases there had been but one death. Opium and morphia were not used, but bromide of potassium was given in the evening if there was persistent sleeplessness; chloral was also given in special cases, but never more than one hundred and twenty grains in twenty-four hours.

Dr. Chas. K. Mills, referring to Dr. Pepper's remarks, said that he had seen a number of cases in which alcohol had developed a latent gout, or neuralgia, and even some forms of local palsy, paresis, or spasm. No class of nervous disorders respond so well to treatment as those due to alcohol in cases of gouty diathesis.

In regard to the relation between alcohol and nervous disorder, he believed that alcohol is a cause of some of the more chronic and prevailing nervous diseases. Sclerosis of brain and cord and peripheral neuroses may be due to the abuse of alcohol; but it is somewhat difficult to decide its exact influence, because such patients have generally been the subjects of syphilis and other excesses besides alcohol. The changes observed post mortem, however, in the tissues of the nervous system are much more likely to be due to alcohol than to syphilis. Epilepsy is often developed by alcohol, and cerebral meningitis of chronic form. In the case of a man who has used alcohol for years, there is enlargement of the Pacchionian granulations, and over the median and convex surfaces of the hemispheres the pia mater is milky-white or amber color; the dura mater also shows inflammatory change,—usually internal pachymeningitis of low grade and slow formation. Whether the alcohol acts upon the affected organs primarily or secondarily he was not able to decide positively, but thought that often it did act directly.

Dr. John B. Roberts remarked that alcohol may be used as an accessory article of food with advantage when used in moderation, in the opinion of Dr. Carter, of London; but the same argument would apply to the use of arsenic in Styria. Alcohol is a poison, and could not be used with impunity. The effect of alcohol upon the special senses is seen perhaps to better advantage by those who are called upon especially to treat diseases of the eye. Retinitis is frequently attributable to this cause, especially where it is combined with tobacco; retinitis potatorum is a condition generally recognized.

Delirium tremens had been referred to as being caused by the sudden withdrawal of stimulants; but he had seen a great many cases of traumatic delirium in drunkards following injuries. The highest temperature he had observed in such a case was 108° F., just before death.

Dr. W. S. Little doubted very much if it would be possible to diagnose a case of retinitis due to alcohol from another depending upon the nervous system. In a case of alcoholism the optic nerve is "dirty," there is intense redness, the vessels slightly smaller, some retraction of the field of vision,—scotoma,—from a cause not in the retina, but due to failure in the optic nerve itself. It

would be difficult to see a retinitis except in this way.

He had seen the same tremor in the ciliary muscles which is noticed in the other muscles, and thought that the "roaches and mice" seen by the patient are due to emptying of the retinal vessels, the ciliary muscles having the same effect upon the circulation of the blood in the retina as the voluntary muscles have upon the circulation in the leg. Color-blindness he had seen caused by alcohol, which was relieved by cutting off supplies of alcohol and tobacco.

Dr. J. Ashhurst, Jr., said that one point in regard to the effect of injuries in the development of delirium tremens would bear further remark. Some cases exhibit these effects in a different way from those alluded to by Dr. Hutchinson. After injury the patients are carried to a hospital, where the diet contains no stimulants, and, as pointed out by Dr. H., they may have delirium tremens as a result. But there is a view lately advanced by Prof. Verneuil, that the injury itself acts in latent alcoholism as an exciting cause. There are cases, in fact, where, from the time of receiving the injury to the outbreak of the alcoholism, the patients are under the effects of alcohol. There is no question of want of supply. Dr. Roberts had confounded traumatic delirium with delirium tremens: the first is the result of undue reaction after shock, and may occur in perfectly temperate men. Travers well described some of these cases under the name of prostration with excitement. These cases are to be treated by a proper amount of stimulant. Delirium tremens is entirely different, and is due to alcoholic poisoning. It may occur without shock after a very slight wound, such as a scalp-wound or the amputation of a finger, or, indeed, no injury whatever. The two conditions should not be confused.

Dr. Hutchinson said in regard to the production of disease of the kidney only by the use of large amounts of alcohol, that while acknowledging the force of the observation we must acknowledge that other organs are affected through the medium of the blood,—for instance, the nervous system, as instanced by another speaker. Moreover, alcohol does not generally produce an acute form, but the chronic or latent form, of Bright's disease, in which the amount of the albumen may be small, or it may be entirely absent from the urine. Therefore it is perfectly possible that even large quantities may be used without producing albumen in the urine.

The effects of tincture of digitalis have been studied by Anstie, who attributes the good effects to the alcohol it contains, as all the experiments made with the infusion were failures. It is not safe to give such large doses as had been recommended of so dangerous a remedy.

He had no doubt of the occurrence of meningitis as a result of alcoholism, and he had reported a perfect illustration of this in the paper. Nor had he any doubt as to the production of delirium by the sudden withdrawal of stimulants, or as to its occasional occurrence after slight injuries in those addicted to the excessive use of alcohol.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, APRIL 14, 1881.

The PRESIDENT, DR. S. W. GROSS, in the chair.

Specimens from a case of obstinate constipation of eighty-seven days, caused by a cancerous stricture of the descending colon. Exhibited by Dr. E. P. BERNARDY.

THE patient, male, aged 25, previous to his last illness had always enjoyed good health. About a year ago, after eating a hearty meal he lay on the floor, and while in this position a child four years old fell from the bed, striking him on the abdomen. This was followed in an hour by a free intestinal hemorrhage, which proved obstinate and only yielded after a week's treatment. Dating from this time, he suffered more or less from colicky pains, accompanied with constipation, which were relieved by purgative medicine. On July 19, 1880, after suffering for a week, and after taking several purgatives to relieve him, finding himself worse, he called in his family physician, who placed him on small doses of mass. hydrarg., ext. belladonnæ, and ext. nucis vomic. This treatment was followed by relief for a few days, when his sufferings returned with increased intensity, and constant vomiting of a bilious matter supervened. The pills were changed to powders of calomel and morphia. On July 31 his bowels were spontaneously opened, making the nineteenth day from his last passage. The abdomen now commenced to be tympanitic. The rectum was then made to take the place of the stomach, beef-tea and brandy injections being ordered.

I saw the patient for the first time on August 1, 1880. He was somewhat emaciated; pulse 120; tongue dry, but not coated, looking somewhat red and irritated; with a temperature of 101°. The abdomen was enormously distended and tympanitic; in the *right inguinal* region was an indurated mass, dull on percussion: there was no pain on the left side. On account of the indurated mass on the right side, I was somewhat dubious as to my diagnosis, but was of the opinion that I had to deal with a stricture. I simply ordered chloral hydrate with morphiæ sulph., and externally flaxseed poultices. By some misunderstanding, I did not see the case again until September 10, 1880, when I was requested to meet Dr. Hooper in consultation. The con-

dition of the patient was in every way worse: all the above conditions were increased, the spasm of the bowels could be distinctly seen through the attenuated abdominal walls, and everything was rejected from the stomach. The indurated mass in the right side had increased in size, having the appearance as if it were about to ulcerate. All medicines by the mouth were stopped, and hypodermic injections of morphia ordered.

The condition of the patient was the same, with slight variations, up to October 1, 1880, when word was sent that the bowels had been opened; but on examination it proved to be the accumulated residue of the beef-tea injections. On the 5th of October the patient suffered greatly from tenesmus. On examination a large hemorrhoid was found protruding. I then passed my hand up the rectum, but detected nothing. Two days after, I repeated the examination, and detected through the walls of the rectum, on the right side, a large tumor, which filled the whole top of the pelvis: it could easily be indented, but it could not be pushed aside. This on post-mortem proved to be the greatly distended lower portion of the ascending colon. Examination of the left side revealed, as I thought, a stricture just at the superior strait. On October 11, 1880, Dr. Curtin was called in consultation. The patient was then suffering the most agonizing pain. Dr. Curtin confirmed my diagnosis. A few days after, to relieve the patient from the abdominal distention, I passed an aspirator needle through the abdominal walls, which gave vent to a large quantity of air.

On Saturday, October 16, 1880, Dr. Parish saw the case with me. The patient was very low, and Dr. Parish suggested the formation of an artificial anus. This I had proposed on my second visit, but was opposed by the family; but I doubt if the operation would have been of any benefit.

The patient gradually continued growing worse. Tuesday afternoon, October 26, 1880, he had a slight passage of a clay color and very offensive. This was the eighty-seventh day from his last passage. On the morning of October 27, 1880, he passed nearly half a chamber-full of the same-colored fæces. His pulse was then 140, he was semi-conscious, and was evidently dying. Death took place on the morning of the 28th of October, 1880, after the most excruciating suffering.

Post-mortem.—Present, Drs. Hooper, Parish, Allis, and Bernardy. Dr. Allis conducted the autopsy, which was made about six hours after death. Body greatly wasted, with every appearance of death from starvation. Abdomen distended and tympanitic. An incision was made from the ensiform cartilage to the pubes, and a second along the lower border of the ribs: this brought all the intestines directly into view, greatly distended, and of a dull silver color, with the arteries greatly enlarged. Both the small and large intestines were dilated, the latter the most. The usual displacement in such cases was present,—viz., a letter U displacement of the transverse colon. A remarkable feature in the case was the pushing up of the liver, so that its lower surface was on a level with the nipple and about five inches from the lower border of the ribs.

The position of the constriction was in the left iliac fossa, above the sigmoid flexure, and seventeen inches from the anal orifice.

The kidneys and liver were examined, but no disease was apparent. The stomach was somewhat contracted, and pushed up under the sternum.

The examination was confined to the abdomen.

Thursday Evening, May 12, 1881.

The President, Dr. S. W. Gross, in the chair.

Two cases of carcinoma mammæ. Presented by Dr. C. B. Nancrede.

The two cases I have to present for your consideration this evening have been announced to be of special interest because they illustrate the varied course pursued by different cases of the same disease. In brief, their histories are as follows.

Case I.—Mrs. C., aged 32 years, mother of four children, was seen by me in consultation with her attendant, Dr. G. A. Rex, September 3, 1880, when I found the following conditions present. At the lower inner part of her right mammary gland was a hard, circumscribed tumor, of the size of a walnut, which moved with the breast tolerably freely over the pectoral muscle. Under the anterior fold of the axilla was another mass, evidently consisting of enlarged glands, which fully equalled in size the mammary growth, if it did not exceed it in bulk. No tenderness over the tuberosity of the humerus was noted. The tumor had been noticed barely three months previously, which date must have corresponded almost to its incipiency, as the patient said that when she first detected it the growth did not exceed in size a small bean. A broken corset steel had bruised the breast at this point, and the injury had led her to examine the breast. The patient was a robust, healthy woman, and had been delivered only about six weeks when she detected the tumor. Her mother was healthy, but her grandmother had died with carcinoma mammæ. September 26, 1880, I removed the whole gland, with the superimposed skin, dissected off the pectoral fascia, fat, etc., and cleared the whole axilla of its glands, enlarged or not, until the capsule of the shoulder-joint could be readily felt. Antiseptic precautions were used, and the wound healed by the first intention, except the track of the drainage-tubes. The skin was so lax —owing to the recent cessation of lactation

and the consequent shrinking of the breast—that, although the skin was extensively removed, very little tension resulted from the apposition of the cut surfaces. Over seven months after the operation the patient shows no return of the disease.

Case II.—Miss H. R., aged 52, with a clear family history, came to me from a neighboring State on November 25, 1880, with her entire left breast converted into a growth of stony hardness. The growth did not much exceed in bulk the normal gland. The skin over the growth presented a roundish ulcerated surface about an inch and a half in diameter. This ulcer showed the characteristic appearances of carcinoma ulcerans. Between five and six years ago she first noticed the tumor, but in which segment of the gland I am unable to say. The growth slowly increased, with but moderate pain. Neither before nor after the operation could any enlargement of the axillary glands be detected. No tenderness over the upper extremity of the humerus could be discovered. November 29, 1880, the growth was removed, with the whole of the investing skin, part of the pectoral muscle, fascia, fat, etc. No glands could be found to remove. By dissection of the skin from the chest-walls, the enormous wound left was reduced to about one-third and dressed with carbolized oil. The patient did well, and when last heard of had no return of the trouble, although a small central spot, owing to tension, etc., had declined to heal, but *did not extend in the slightest.* Her health improved markedly after the operation.

It is hardly necessary to indicate the points of interest in these two cases, presenting as they do such a marked contrast as to the contamination of the neighboring lymphatics, and the importance of judging each case upon its own merits, and not upon any preconceived ideas as to when we should, or should not, operate.

Dr. S. W. Gross remarked that one point had been alluded to by Dr. Nancrede which he had been at some pains to test by his own experience,—viz., the presence or absence of tenderness in the region of the greater tuberosity of the humerus in cases of carcinoma. Attention had been lately called to this by Mr. Snow, of London. In the last twenty cases of carcinoma mammæ under his care, careful examination had failed to discover tenderness over this portion of the humerus. *A priori*, such an involvement of the humerus is improbable, since it has been observed that this bone is very rarely affected in secondary cancerous disease of the osseous system. As his own experience in twenty cases totally failed to reveal such tenderness, and as the pathological fact just cited was against it, he was inclined to view the new symptom as worthless as a means of diagnosis.

Dr. Longstreth asked Dr. Gross whether any actual examination of the medulla of the bones had been made in the cases cited from an English source which would prove this supposed involvement of the marrow-cells.

Dr. Gross, in reply, said that he was unaware of any such.

Dr. Longstreth said that he had asked the question because in one specimen examined by him he thought that he had found the medulla cells affected. He would like to ask the experience of the members as to whether the amount of cells, the signs of their active proliferation, and the involvement of the surrounding tissues could be relied on as to the rapidity of the return or the likelihood of metastasis, and related several cases where he had been induced by such appearances to predict a rapid recurrence, but where the course of the cases completely refuted his opinion.

Dr. S. W. Gross, in reply, said that if Dr. Longstreth continued to examine such cases and make similar prognoses he would find his opinions justified by rapid returns and dissemination in the majority of cases. In general terms, the less connective tisue, the greater malignancy.

Dr. Nancrede remarked that he would like to relate the ultimate result of a case of somewhat similar disease, which illustrated the extreme rapidity of course pursued by malignant growths where the cells were at a maximum. The members might perhaps recall a specimen exhibited by him before this Society, about a twelvemonth since, of large spindle-celled sarcoma of the breast, which had been opened by the attending physician in mistake for a chronic abscess, so deceptive was the sense of fluctuation produced by the excessive softness of the growth and the hemorrhages occurring in its substance. In removing it, Dr. Nancrede only succeeded in saving its pseudo-capsule and one or two small fragments for microscopic examination. In four months the lungs were crammed with deposits, which terminated this lady's life in about nine months after operation, and less than one year from the first appearance of the disease.

REVIEWS AND BOOK NOTICES.

A Treatise on Bright's Disease and Diabetes. By James Tyson, M.D. Philadelphia, Lindsay & Blakiston, 1881.

Of the 310 pages of this book 226 are devoted to a consideration of the various affections which are habitually grouped together under the name of the famous London physician, and the rest are set apart for diabetes. In the Bright's group Dr. Tyson recognizes six individual affections,—acute and chronic parenchymatous nephritis, lardaceous disease, interstitial nephritis, suppurative interstitial

nephritis, and cyanotic induration. When the chapters which treat of these affections are studied, it will be found that they embody all that is known concerning the disease of which they treat. Whilst the historic side of the various subjects is not at all neglected,—the author evidently being equally well read in the literature of the past and the present,—the modern developments of the scientific and clinical aspects of the diseases have been elaborately and carefully studied, and the well-digested results given at length to the reader in a clear and agreeable form. There is at present no great English practice of medicine fully representing the science and art of the day, and comparable to the treatises of Watson and Wood as we studied them in our youthful days. Such a monograph as the present would well make a section of a general work of the old style; and perhaps it is better that the practitioner should fill his library with these brief, sententious monographs written by various hands than be dependent upon a single classic treatise, the output of one great mind.

A New Form of Nervous Disease—Essay on Erythroxylon Coca. By W. S. Searle, M.D. New York, Ford, Howards & Hurlbut, 1880.

We have read enough of the first of these essays not to want to read more. When an author believes that "the delicate and weakly may imbibe strength and vitality from rubbing at the hands of a vigorous man or woman," we think he ought to rub his own *caput* against some head which contains a little common sense. The new disease may possibly be a disease in the sense that athetosis, neurasthenia, etc., are called diseases,—*i.e.*, in being either a symptom or a condition,—but is characterized so unscientifically by Dr. Searle as to excite deserved ridicule. "A distinctive phenomenon," we are told, "is passive congestion, usually of the cerebellum only." Evidently the doctor is furnished with the double-million-magnifying gas microscope of hextra power, that the well-known Samuel Weller thought would be necessary to enable him to run up two flights of stairs, round one corner, and through a two-inch deal door, and is able, even in a negro with a thick skull, to watch the play of the blood-supply in the inmost cerebellum. It is a pity that we commoner mortals are not also possessed of so valuable an instrument.

Medical Electricity. By Roberts Bartholow, M.D. Philadelphia, H. C. Lea's Son & Co., 1881.

This is a well-put-together, handsomely illustrated treatise of over 260 pages, written in the author's popular style. Evidently a successful book; not remarkably original, but showing a thorough acquaintance with the subject; mostly sound in its teaching, but occasionally erring in the dogmatic statement of asserted truths whose character is, in truth, doubtful. Witness the account of the effects of galvanization of the sympathetic ganglia of the human neck from the outside of the body,—the statement on page 98,—"The direct application of the continuous galvanic current to the superior ganglion of the sympathetic contributes to the activity of the circulation, re-establishes it when arrested," etc.; also the assertion on page 183 as to the curative powers of galvanism in migraine.

A Text-Book of Practical Medicine. By Dr. Felix von Niemeyer. Revised Edition. New York, D. Appleton & Co., 1881.

In 1871, Prof. Niemeyer passed from his earthly labors, and the present volumes are not, in truth, the work of his hands. In 1880, Dr. Eugene Seitz edited a posthumous edition of the work, cutting and slashing, modelling and adding, until the book was scarcely more Dr. Niemeyer's work than a piebald circus-horse is a bay mare. The present volume is an attempt upon the part of Drs. George H. Humphreys and Charles E. Hackley, of New York, to make the book of Dr. Seitz resemble more closely the original work of Prof. Niemeyer. A good treatise upon the practice of medicine has been the result; but it should have been entitled "A Practice of Medicine founded upon that of the Late Professor Niemeyer."

Anatomical Studies of the Brains of Criminals. By Moritz Benedikt. Translated by Dr. E. P. Fowler. New York, Wm. Wood & Co., 1881.

This book consists of very detailed descriptions, fully illustrated by wood-cuts from photographs, of a number of brains of criminals. The brains were all more or less defective, especially in gyrous development, the fissures being accordingly abnormally large. The book is of value as a solid contribution to psychological anatomy, but will hardly interest the general medical reader.

GLEANINGS FROM EXCHANGES.

Removal of a Kidney on Account of Uretro-Uterine Fistula.—Crédé (*Archiv f. Gynäk.*, Bd. xvii. Hft. 2; *Edinburgh Medical Journal*) extirpated the right kidney in the case of a fistula the result of a parametric abscess following labor. There was a constant flow of urine from the vagina, while at the same time urine was passed in the natural way, and no fluid could be forced out of the bladder into the vagina. By means of a speculum the urine was seen to flow through the os uteri. On dilatation of the os and examination of the cavity of the uterus, a small depression in its upper right side was found, through which the urine gained access to the uterus. The operation was successful.

NEW BASE FOR OINTMENTS AND SUBSTITUTE FOR LARD.—Dr. J. B. Moore (*Druggists' Circular*, July, 1881) recommends the following:

℞ Lard, 16 troyounces;
White wax, 4 troyounces;
Cosmoline, 4 " "

Melt the wax by means of a water-bath, add the lard and cosmoline, and stir the mixture occasionally until liquefied, and, if necessary, strain through muslin. Stir the mixture constantly until cool.

The mixture should be allowed to cool at the ordinary temperature. If the refrigeration is urged by placing the vessel in cold water, as is sometimes injudiciously done, there is danger of causing irregular solidification.

BELLADONNA - POISONING SUCCESSFULLY TREATED BY PILOCARPIN.—Dr. Grattan (*Lancet*, vol. i., 1881, p. 951) was called to see a woman who had swallowed, by mistake, fʒii fʒii of lin. belladon. (B. P.), apparently a favorite beverage of the English lower classes, if we may judge by the number of cases where it is swallowed purposely or by accident. Dr. Grattan, after washing out the stomach, gave a hypodermic injection of one-fifth of a grain of pilocarpin, repeating the injection thrice at intervals of fifteen minutes, four-fifths of a grain having thus been given. The patient recovered.

MISCELLANY.

RABIES INOCULATED BY CEREBRAL SUBSTANCE.—Prof. Pasteur and his assistants have on different occasions, and often with success, inoculated the medulla oblongata, and even the frontal portion of one of the hemispheres and the cerebro-spinal liquid, with the product obtained by the expression of the substance of the brain of a rabitic individual. Under these circumstances the rabies has always exhibited the ordinary period of incubation. The saliva, therefore, is not the sole seat of the rabid virus, the brain also containing it, and being there possessed of a virulence at least equal to that met with in the saliva of rabid animals. Prof. Pasteur hopes to shorten the incubation of his experimental rabies, so that he will not have to wait so long to observe the effects of inoculations. He says everything is prepared in his laboratory for carrying on the study of rabies on a most extensive scale.

DR. CHARLES T. HUNTER has been appointed Demonstrator of Anatomy in the University of Pennsylvania in succession to the late Dr. Hodge, and Dr. J. William White has been appointed Demonstrator of Surgery in Dr. Hunter's place.

AFTER personal use, we can commend the Arthur Gynæcological Chair as very well made and very well adapted to its purpose.

ACCORDING to trustworthy medical reports, the Isle of Wight is in a dangerously unsanitary condition, and intending visitors are warned off by the English medical journals.

ANOTHER MASK FOR THE ODOR OF IODOFORM.—Dr. Peterson suggests a drop of tincture of musk to the ounce of iodoform, whether in a solid or a liquid form.

THE twenty-fifth anniversary of Dr. Rudolph Virchow's appointment as Professor in the University of Berlin is to be celebrated on October 13.

NOTES AND QUERIES.

AMERICAN OTOLOGICAL SOCIETY.

THE Fourteenth Annual Meeting of the Society will be held in Newport, R.I., on Tuesday, July 26. The following papers have been announced. 1. "Suggestions regarding the Treatment of Suppurative Otitis." Dr. S. Theobald, Baltimore, Md. 2. "On the Value of Operations in which the Tympanic Membrane is Incised." Dr. D. B. St. John Roosa, New York, N.Y. 3. "On the Tuning-Fork in Diagnosis." Dr. D. B. St. John Roosa. 4. "On the Use of Calcium Sulphide in Inflammatory Diseases of the Ear." Dr. Samuel Sexton, New York, N.Y. 5. "The Relative Frequency of Disease of the Right and the Left Ear." Dr. R. C. Brandeis, New York, N.Y. 6. "Removal of Foreign Body by Disarticulation of the Auricle." Dr. J. Orne Green, Boston, Mass. 7. "Malignant Growth in the Naso-Pharynx, with Early Aural Symptoms." Dr. C. H. Burnett, Philadelphia, Pa.

Secretary,
DR. I. I. B. VERMYNE,
80 Spring Street,
New Bedford, Mass.

THE American Surgical Association will hold its first regular meeting at the Oriental Hotel, Coney Island, September 13, 14, and 15. Papers are expected from several gentlemen.

THE Fifth Annual Meeting of the American Dermatological Association will be held at Newport, R. I., on August 30 and 31 and September 1.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM JULY 10 TO JULY 23, 1881.

SIMONS, JAMES, LIEUTENANT-COLONEL AND SURGEON.—Granted leave of absence for one month. S. O. 120, Department of the East, July 15, 1881.

AINSWORTH, F. C., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Fort Clark, and assigned to duty as post-surgeon at Fort McIntosh, Texas, relieving Assistant-Surgeon Gorgas. S. O. 90, Department of Arizona, July 14, 1881.

MAUS, L. M., CAPTAIN AND ASSISTANT-SURGEON.—Now awaiting orders in Washington, D.C., to report in person to Commanding Officer, Davids' Island, N.Y.H., for temporary duty at that post. S. O. 158, A. G. O., July 13, 1881.

COMEGYS, E. T., CAPTAIN AND ASSISTANT-SURGEON.—Now awaiting orders at Cincinnati, O., to report in person to Commanding Officer, Columbus Barracks, O., for temporary duty at that post. S. O. 158, c. s., A. G. O.

GARDINER, J. DE B. W., CAPTAIN AND ASSISTANT-SURGEON.—The extension of leave of absence granted him in S. O. 59, March 14, 1881, from A. G. O., further extended six months. S. O. 157, A. G. O., July 12, 1881.

SHANNON, WILLIAM C., CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty with escort to the commission from Fort Bridger to the Uintah Agency. On return of commission to Bridger, to rejoin his station, Fort D. A. Russell. S. O. 62, Department of the Platte, July 6, 1881.

GORGAS, W. C., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—When relieved at Fort McIntosh, Texas, to report to Commanding Officer, Fort Duncan, Texas, as post-surgeon. S. O. 90, c. s., Department of Texas.

PHILADELPHIA, AUGUST 13, 1881.

ORIGINAL COMMUNICATIONS.

VACCINATION.

Read before the Philadelphia County Medical Society, May 25, 1881,

BY W. M. WELCH, M.D.,
Physician to the Municipal (Smallpox) Hospital.

THE Society having requested that the subject of vaccination be presented for discussion, its Directors have honored me with the invitation to make the introductory remarks. In accepting as I do with pleasure this invitation, it is not my purpose to enter into anything like an elaborate discussion of this comprehensive subject, nor shall I be able within the short space of time at my disposal to even touch upon all the points of interest, but I propose merely to direct attention to and invite discussion on some of the more important and practical points in connection with this vastly important subject. The topics, therefore, which I have selected are as follows:

1. What conditions of the system contra-indicate vaccination? Does pregnancy forbid its use?
2. What is the best method of performing vaccination?
3. The course of true vaccinia.
4. The comparative value of humanized and bovine lymph.
5. The prophylactic power of vaccination.
6. Does vaccination in infancy protect through life?
7. What is the value of revaccination?

When vaccination is to be performed, it is of course desirable that the child should be in a good state of health. Acute diseases and cutaneous eruptions of all kinds are generally regarded as contra-indications, and among the latter affections herpes, eczema, and intertrigo are said to be very liable to interfere with the regular course of the vaccine vesicle. But under exposure to the variola contagion no condition of the system should stand in the way of vaccination. Under such circumstances I have frequently vaccinated persons suffering from measles, scarlet fever, chicken-pox, etc., and with no unpleasant results, but, to the contrary, have prevented variola.

While it is desirable that an infant should attain the age of at least three months before vaccination is performed, yet when there is immediate risk of infection no age is too early. I have repeatedly vaccinated infants on the day of their birth without any untoward effects.

A question about which there seems to be a good deal of confusion, and one which has been answered both affirmatively and negatively, is, Does pregnancy forbid vaccination? In times of smallpox prevalence I have found no difficulty in answering this question to my own satisfaction and guidance. Though my experience in this direction is not very great, I have seen nothing to lead me to believe that pregnant women incur any special risk under vaccination. Of this, however, I am very certain, viz., that smallpox among pregnant women is very fatal: abortion generally occurs, and death is the usual result. To justify, therefore, excepting pregnant women from vaccination, particularly under circumstances of exposure, it ought to be shown that the risks from vaccination are as great as from smallpox; and this I am sure has never been done.

The late Dr. Charles D. Meigs, regarding cowpox and smallpox as identical in nature and as only differing in intensity, said,* "Do not vaccinate them [pregnant women]. I have been the witness of dreadful distress from the operation. Eschew it, I entreat you."

On the other hand, Dr. Barnes's experience seems to justify the following conclusions:†

1. "Pregnant women living under epidemic or zymotic influences are more prone to take the prevalent morbid poison than others.
2. "Having taken a morbid poison, they are less able to throw it off.
3. "Their system is less able to resist its injurious action. Abortion and a most dangerous form of puerperal fever are very likely to follow."

Dr. Barnes thinks we may conclude, in the absence of decisive evidence of special danger, that "pregnant women are entitled to equal protection against smallpox with the rest of the community, and that vaccination or revaccination should be practised on pregnant women, in their own

* Females and their Diseases, p. 575.
† Half-Yearly Abstract of the Medical Sciences, July, 1871.

interest, as well as in that of the community of which they form a part."

The next topic to which I shall invite attention is, *What is the best method of performing vaccination?* This question is often asked by younger physicians, and I do not wonder at it, because little or no instruction is given on this point in our medical colleges. The frequent failures that follow the operation, and often spurious results pronounced genuine and protective, fully attest the fact that there is a great deal of carelessness, if not downright ignorance, often displayed in the simple yet important matter of vaccination. During an epidemic prevalence of smallpox nothing is more common than admission to the hospital of unvaccinated patients, stating that they had been vaccinated several times,—perhaps recently,—and that it would not "take;" and their doctor is often quoted as saying that it failed to "take" because their blood was too pure.

Now, if vaccination in an unprotected person is skilfully performed, and with well-selected vaccine virus, failure to "take" should be very uncommon, for I believe there are but very few persons insusceptible to vaccinia. Mr. Marson says that "with good lymph and the observance of all the proper precautions, an experienced vaccinator should not fail of success in his attempts to vaccinate above once in one hundred and fifty times."

The first important step in the operation is to secure a state of perfect solution of the virus to be used. Carelessness in this particular will often result in failure, not only in the use of humanized crust, but also of dried bovine lymph, as usually obtained on ivory points. I apprehend that a common cause of failure in the use of the latter material is that the points are often applied to the abraded surface of the arm, depending upon the exuded blood to dissolve the dried lymph. Instead of this, if a perfect solution of the virus is secured before the application is made, failure should rarely occur, provided the lymph has been properly collected and has not lost its virtue by age.

As regards the best mode of inserting the lymph, I prefer an ordinary thumb-lancet, with its point decidedly dull. Holding the skin at the place of insertion on the arm tense, I carefully make a few longitudinal incisions, drawing but little blood; then, grasping the arm in its circumference, I stretch apart the small incisions and press the lymph thoroughly into them, either with the lancet or ivory point. By this mode of procedure, and with active virus well dissolved, I very seldom fail to produce in an unprotected person the vaccinal effect. In my judgment, all machines and gimcracks devised especially for performing vaccination are far inferior to the lancet when used with care and skill.

The Course of True Vaccinia. — The regular succession of phenomena that constitute true vaccinia are so familiar to all that I need not stop to describe them minutely, but will be content with directing attention to some of the essential characteristics in its course which I fear are frequently not secured and often undervalued. The careful examination of many thousand vaccine cicatrices on the arms of persons vaccinated in this country and very many European countries fully convinces me that the importance of securing a true Jennerian vesicle is not duly appreciated; and in no country, I am sorry to say, is this want of appreciation more apparent than in the United States. I have been in the habit of carefully examining, for purpose of classification, all vaccine marks of patients admitted into the Municipal Hospital of this city for the past ten years, and the result proves, as my reports from year to year show, that the patients of German birth bear evidence of having had the most thorough, and those of American birth the most careless, vaccination. A perfect vaccine vesicle, pursuing its regular course undisturbed, is sure to leave an indelible scar, presenting certain peculiar characteristics. A cicatrix, therefore, that is far from being typical is evidence that the vesicle has not been of the true Jennerian type, and cannot be so well trusted to afford protection.

In perfectly typical vaccinia, papulation is noticed on the third or fourth day after insertion of the virus, the vesicle begins to form on the fourth or fifth day, the areola should be well marked on the ninth or tenth day, and the crust falls off spontaneously about the twenty-first day. The areola and some slight febrile reaction which accompanies it may, I think, be regarded as essential to true vaccinia. The earlier writers on vaccination, and especially Jenner, went so far as to say that

vaccination unattended by febrile reaction was spurious, and consequently conferred no protection against smallpox, and that in all cases of post-vaccinal variola the alleged vaccination had been of this spurious character. Concerning the correctness of the latter view I think there is much room for doubt, as we shall see farther on.

In order to secure the typical vesicle which has been described, it is necessary that the material used should be of the best quality; and in this connection let us consider *the comparative value of humanized and bovine lymph.*

There is but little difference between the course of vaccinia induced by animal virus and that by virus of recent humanization. Although the former is frequently objected to on the ground that it is dangerously violent in its action on infants, yet I believe the inflammatory action produced by virus of one, two, or three human removes is rather the more intense of the two. But lymph of very long humanization—that which has been transmitted from arm to arm for many years—seems to lose very much of its former vigor. Prior to the introduction of animal lymph into this country by Dr. Henry A. Martin, of Boston, the humanized virus then in general use induced vaccinia of rather shorter duration and of less violence than that which is induced by either the animal or the humanized virus in general use at the present time. It would, I believe, be impossible to find any of the old stock of humanized lymph now in use in this country, it having been entirely supplanted by animal lymph and lymph of recent humanization.

Although the course of vaccinia induced by long-humanized virus is somewhat diminished in its duration and severity, yet I think proof is needed to show that on this account it loses any of its prophylactic power. During the epidemic of smallpox in this city in 1871–72, when vaccination was put to the severest possible test, and when little or no virus was in use but that of long humanization, smallpox did not attack those who had been recently well vaccinated. Furthermore, I have over and over again seen vaccinia induced by this virus, inserted after undoubted infection by the variola contagion, confer complete and absolute protection against the disease; while under the same circumstances I have, I believe, during the present epidemic of smallpox, failed in all primary vaccinations to confer immunity when animal lymph has been used. This is not because vaccinia induced by animal lymph is less protective, but because the course of the process is slower, the areola often being two or three days later in appearing; and as we regard the areola and febrile reaction as evidence of systemic impression, and consequently of protection, this difference in time is often of vital importance to a person vaccinated after exposure.

As showing still further that humanized virus of long descent retains the power of inducing vaccinia of the highest degree of excellence, I refer again to the fact that in no country is vaccination carried on more thoroughly and satisfactorily than in Germany, and in that country humanized virus is generally employed. I believe the usual method of performing vaccination in Germany is by the use of eighth-day lymph, commonly practising what is called arm-to-arm vaccination. This method, when practicable, is doubtless the very best; for fresh eighth-day lymph is very certain to succeed, and can only produce true and genuine vaccination, never spurious results.

Until quite recently the vaccine crust has been the form of virus generally used in this country, and with proper care in its selection as good results may be obtained from this form as from any other. It is, however, of prodigious importance that the crusts should be selected only from healthy infants, and from those in whom the vaccination has been characterized by perfect, typical, undisturbed vesicles. The surprisingly large proportion of imperfect and uncharacteristic cicatrices that have resulted from vaccination in this country clearly indicate that vaccine crusts have not been selected with sufficient care and judgment; and to this negligence, I believe, is due the apparent deterioration of humanized lymph of long descent.

After thirty years of experience in the transmission of humanized lymph, Jenner admitted that it may degenerate from want of due care in the selection of subjects, but spoke of its alleged degeneration by mere lapse of time as a "conjecture he could destroy by facts." My arguments thus far are in full accord with this view of Jenner, but I am willing to go further and say that I believe the same want of care in the selection of subjects from whom lymph is taken would also render it liable to serious

contamination. I can, perhaps, very well illustrate my view of humanized virus by comparing it to a stream of water, which may preserve the level of its source, but cannot rise above it; and, as the stream is liable to be contaminated in its course, we are certain of obtaining the purest water from the spring. And so I believe the original source of all vaccine virus—animal lymph—should have our decided preference, if for no other reason, because of its well-known purity.

The communication of any of the ordinary cutaneous diseases, or even scrofula, by vaccination, may be regarded as doubtful. But, certainly, I cannot be considered as an alarmist when I say that there is a possibility—nay, indeed, real danger—of syphilitic infection through the use of humanized virus. That there are well-authenticated cases of vaccinal syphilis on record cannot be denied by any one who has carefully examined the literature on the subject. It is true the danger is not very great, and fortunately can be almost wholly avoided by care, so that after all we are confronted by no valid objection against vaccination, even though there were no other than humanized virus at our command. I quite agree with Dr. Martin, who has so well said,* "If our dilemma was either to abandon vaccination or to practise it notwithstanding a possibility of transmitting syphilis in the operation, I should not hesitate at all: I should continue vaccination, using every possible care to insure the purity of the virus I made use of. But there is no such dilemma. Vaccination can be done in the best possible manner with virus to which no suspicion of syphilitic contamination can attach." Of course, the virus referred to is bovine. I have already alluded to the fact that to Dr. Martin belongs the credit of the introduction of animal lymph into this country. In 1870 he sent his special agent to Europe for the express purpose of procuring some of the original Beaugency "stock." This agent succeeded in his mission, and returned in September of that year, when Dr. Martin at once began the systematic propagation of animal lymph, and, after great labor, large expenditure, and no little anxiety, succeeded in establishing in this country a "service" of animal vaccination, where lymph can be procured in great abundance, possessing well-tested prophylactic power.

Dr. Martin's success, together with the increasing demand for bovine virus, has induced very many enterprising persons to enter the field as competitors, some of whom doubtless possess the requisite knowledge and ability to carry on the work successfully and to produce virus of undoubted excellence; but there are others, I fear, who, without any fitness for the work, not even realizing its responsible nature, are engaged in propagating and selling so-called "bovine virus," the frequent failures and spurious results from which threaten great injury to the cause of animal vaccination. For some time past I have frequently met with a peculiar form of spurious vaccination, resulting from the use of some of the so-called "reliable bovine virus" now being sold in this city by apothecaries. It consists of a pseudo-vesicle, containing at first a little serum and blood, but soon becoming dense and of a bright-red color, resembling in some respects, when fully formed, a nævus or red raspberry. It is entirely different from any spurious vaccination that I have ever seen from humanized virus, and that it is wholly devoid of prophylactic power I have had abundant opportunity to prove.

For the better protection of citizens against a pestilential disease which is constantly recurring, and which is frequently most destructive to business and commerce, the propagation of animal lymph of perfect quality is of so great importance to the public that it should not be left solely to private enterprise, nor degraded to the level of a commercial trade, but should be under the control of the national or State government, where lymph of undoubtedly good quality could always be obtained free of cost. If this were so, there certainly could be no reasonable objection against the enactment of a law making vaccination compulsory.

The Prophylactic Power of Vaccination.—As regards the protection afforded by vaccination against smallpox, the facts are so numerous that it is difficult to know whence to select examples. Countries in which vaccination is most carefully and systematically performed furnish the strongest proof of its prophylactic power. In Bavaria and Sweden, where the laws regulating vaccination are perhaps the most rigid, variola has ceased to be an infantile

* Transactions of the American Medical Association for 1877.

disease. In Sweden, during the pre-vaccinal period, from 1774 to 1801, the annual average of deaths per million of inhabitants from smallpox was 1973; after vaccination was introduced, but was not obligatory, — 1802 to 1816, — the annual average per million inhabitants was 479; and after vaccination was made compulsory, during the period from 1817 to 1877, the annual average of deaths from smallpox per million of population was only 181. This shows an annual saving of life of 1792 persons out of every million of the population by vaccination, and fully justifies the law making it compulsory.

Mr. Marson's statistics, collected during thirty years of labor at the Smallpox Hospital of London, clearly prove the power of vaccination in modifying smallpox. During this period fifteen thousand cases came under his care, and he found that the unvaccinated died at the rate of thirty-five per cent., while those who had been vaccinated — in infancy, I presume — died at the rate of only six and a half per cent.

Observations made by myself show substantially the same facts. During the last ten years over four thousand cases of smallpox have come under my personal care, and within that period our city has been visited by one of the most malignant and wide-spread epidemics of which we have any record, thus subjecting vaccination to the severest possible test; and the results abundantly sustain its time-honored reputation as a most valuable protective agent. Of the four thousand cases, the unvaccinated have died at the rate of about sixty per cent., while those having been vaccinated in infancy and showing a good cicatrix died at the rate of about ten per cent. Although the death-rates are very large, for reasons which I will not stop to explain, yet the difference in favor of vaccination is certainly very great.

The examples so far given chiefly show the modifying influence of vaccination against smallpox; but vaccination is capable of doing more than that: it will afford perfect protection when recently and thoroughly done. During the past twelve months I have had under my care at the hospital about twelve hundred cases of smallpox, and of this number *only one* had been recently vaccinated. In this case vaccination had been done six months previously, and the cicatrix was of such a character that I was obliged to classify it as "fair." The disease was but slightly modified, if at all, but terminated by recovery. According to my experience, smallpox under such circumstances is so entirely exceptional that I cannot help questioning the genuineness of the vaccination, though the cicatrix was fair. I have taken the pains to write to the physician (residing in the country) who performed the vaccination, inquiring as to the material used, the course of the vaccinia, etc., but have received no reply. As showing still further the efficacy of recent vaccination, I must add that I have more than once seen a recently-vaccinated infant live in an atmosphere charged with variola contagion, and take its usual supply of nourishment from its mother's breast while the mother was suffering from a tolerably severe attack of smallpox, and the infant remain free from infection. Surely proof stronger than this is not needed to convince any intelligent, thinking person of the prophylactic power of vaccination.

Does Vaccination in Infancy Protect through Life?—It was formerly believed by all physicians, and, I think, is yet by very many, that a genuine vaccination in infancy loses none of its protective power throughout the lifetime of the individual. Now, any one who will take the pains to consult the statistics of a smallpox hospital must come to the conclusion that vaccination at first affords complete protection, or nearly so, and that the susceptibility to smallpox gradually returns and progressively increases throughout childhood and adolescence and up to an undetermined period in adult life.

According to my experience, smallpox after thorough vaccination rarely occurs within the first seven or eight years of life, and I think I may add that up to this age death never results, unless from some complication. But from this age up to the period of puberty the number of cases increase, and death is not infrequent. During the period of youth and adolescence the number of cases very greatly increase, and death becomes quite common. Within the period of life from fifteen to thirty-five years of age post-vaccinal smallpox is of exceedingly frequent occurrence, even when the vaccination of infancy has been most thorough and complete. I have frequently seen smallpox, and often of the worst type, in persons presenting most typical vaccine cicatrices, sometimes to

the extent of six or more on each arm. The sooner the profession recognizes the fact that a vaccine cicatrix, however typical, resulting from vaccination in infancy, is not proof of immunity from smallpox throughout life, the better it will be for the protection of the public against the constantly-recurring epidemics of smallpox, because it would lead to a more general practice of revaccination.

What is the Value of Revaccination?—I am convinced that there is a great deal of confusion in the minds of physicians as to what constitutes a successful revaccination. Many believe that because the vesicle and areola do not observe the typical course of true vaccinia the effect is therefore spurious,—merely the result of local irritation,—and possesses no protective value. But why should we not have modified vaccinia, or vaccinoid, after a primary vaccination, as well as modified smallpox, or varioloid? Certainly there is no reason why we should not. And I believe that as varioloid differs in various degrees of severity from true variola, so likewise does vaccinoid differ from true vaccinia. If this is true, we may then conclude that as varioloid gives protection against a second attack of smallpox, so also does vaccinoid exhaust the return of susceptibility to the disease.

Of persons vaccinated in infancy, the proportion in youth or adult life who are susceptible to revaccination to a greater or less extent may be put down, I think, at about seventy-five per cent. Dr. Martin's statistics show that with animal lymph his success "is very exactly seventy-three per cent. at the first attempt. If those cases which fail to be affected at this first trial are twice more attempted, the result is raised to a fraction over eighty per cent." Dr. Warlomont, of Belgium, who has also had extensive experience in the use of animal virus, gives his success in revaccination as sixty-two per cent., resulting, presumably, from the first attempt. Of course the proportion of successful revaccinations in any community will depend largely upon the character of the primary vaccinations. In this country, where vaccination has been so carelessly and imperfectly performed, we should expect to find revaccination successful in a larger proportion of persons than in some other countries where the operation is conducted with greater care.

Revaccination is thought by many to be necessary only where there has been some defect in the primary vaccination; but as it has already been pointed out that smallpox not unfrequently occurs after the most perfect vaccination, it is therefore evident that revaccination should be generally practised, and without regard to the character of the vaccine cicatrix. The age at which revaccination is called for may be inferred from what has already been said concerning the return of susceptibility to smallpox after vaccination in infancy. When there is danger of infection, I should say that it is wise to revaccinate all persons who have been vaccinated longer than five years, though children under seven or eight years of age will rarely be found susceptible to the vaccinal effect; but subsequent to that age, particularly about and after puberty, it is of extreme importance that revaccination should be performed.

That revaccination destroys again the renewed susceptibility to smallpox cannot be doubted, since there is abundant proof in support of this fact to be found wherever it has been carefully and systematically performed.

It has already been shown that in no country is vaccination carried on with greater care and thoroughness than in Germany. Almost every infant is vaccinated within the first year of life, and revaccination is usually performed about the twelfth year. In addition to this, every person entering the army is again vaccinated, and if this fails it is repeated again and again until the vaccinal effect is produced or the surgeon is satisfied that the person is insusceptible to vaccinia. Consequently the German army is well protected against smallpox, as official statistics prove. During the Franco-Prussian war, smallpox prevailed to an alarming extent, and both armies were freely exposed to the contagion; but the loss by death from that disease in the German army was only two hundred and sixty-three men, against twenty-three thousand four hundred and sixty-eight in the French army; and the latter was never much more than one-half the size of the former. In the French army vaccination and revaccination were in no wise compulsory. Of the large accession of recruits, many had never been vaccinated; and, as there was no rule enforcing revaccination, the army was largely unprotected against smallpox. The great

loss of life which the French army sustained by an eminently preventable disease was doubtless owing to the want of proper appreciation of vaccination on the part of the government, as evinced by the paltry sum of money appropriated for vaccine purposes. The same mistake, I fear, is now being repeated by our City Councils, who, in the face of an epidemic of smallpox of more than ordinary magnitude and virulence, have rejected the request of the Board of Health for an appropriation to carry on gratuitous vaccination.

A very striking example of the value of revaccination is given in a recent number of the *British Medical Journal.* Some eight or nine years ago, when smallpox was very prevalent, the surgeon to a large sailing-vessel discovered, when a few days out at sea, that the captain, in flagrant violation of the rules, had secretly conveyed on board the vessel his son suffering from confluent smallpox. The surgeon at once procured all the vaccine lymph that he could, and revaccinated as many of the crew as it sufficed for. Unfortunately, about one-third or one-fourth of the crew remained unvaccinated. "Of the revaccinated—two-thirds or three-fourths of the whole number—*not a single one* had caught the disease; but of those who, from no choice of their own, had remained unvaccinated, *all, or all but one or two,* caught the disease, and three died."

Referring again to Marson's very precise statistics, we find proofs that smallpox is very rare after revaccination. He asserts that but few patients have been admitted into the hospital with smallpox who stated that they had been revaccinated with effect, and that these few had the disease in a very mild form. For over thirty years, during his connection with the hospital, he revaccinated all the nurses and servants, who had not had smallpox, on their coming to live at the hospital, and *not one of them* contracted the disease. At a time, however, when a large number of workmen were employed about the hospital, most of them consented to be revaccinated, but there were a few who declined, and of these two took smallpox, while the former remained perfectly protected.

In the experience of the medical superintendents of the several smallpox hospitals of London, during the period from 1876 to 1879, when 11,412 cases of smallpox occurred among vaccinated persons, *not one case* occurred, within the cognizance of either of the medical superintendents, of any person who had been efficiently vaccinated and successfully revaccinated. Of the nurses and servants employed at the various hospitals, numbering about one thousand, some half-dozen only contracted the disease, and these for some cause or other escaped revaccination before entering the wards.

My own experience entirely agrees with that of the observers just quoted. Only very few persons have been admitted into the hospital under my charge with smallpox who presented evidence of having been successfully revaccinated, and these few have had the disease in so mild a form that death has never occurred among them. During the last ten years, no person entering the hospital in any official capacity, whether as assistant-physician, steward, matron, nurse, or other employé, who had taken the precaution to be revaccinated before entering upon duty, has taken smallpox; but, on the other hand, I have seen a few employés, in whom revaccination was omitted, infected by the disease. With such facts as these before me, I feel warranted in concluding that if vaccination were efficiently performed in infancy, and revaccination successfully accomplished at puberty, we might then be able to realize the fact that Jenner was no mere dreamer when he said that vaccination is *capable* of extirpating smallpox from the earth.

CONVULSIONS DUE TO DEPRESSION OF SPINAL REFLEX-INHIBITORY CENTRES;

WITH SPECIAL REFERENCE TO THE CONVULSIONS OF APOMORPHINE, ATROPINE, STRYCHNINE, AND OTHER POISONS.

BY EDWARD T. REICHERT, M.D.,

Formerly Demonstrator of Experimental Therapeutics and Instructor in Experimental Physiology in the Post-Graduate Course in Medicine, University of Pennsylvania.

IT seems to be a prevalent, if not, indeed, an almost universal, belief that convulsions are invariably the result of a direct or indirect stimulation of the cerebral or spinal centres, or of the nerve-peripheries or muscles; and even in the case of certain drugs that in every other respect are either depressant of nervous structures or do not appreciably affect them, nothing is more common when they cause convulsions than to find it stated that the phenomena were due to a stimulation of certain

portions of the nervous system, but of the cord more especially. My attention was first attracted to the erroneousness of this belief a couple of years ago, while experimenting with apomorphine, when I found a coexistent condition of paralysis and convulsions in animals poisoned with it. These animals, it was observed, would lie as if lifeless, and no reflex action could be elicited by any sort of stimuli; yet suddenly a hyperæsthetic condition would appear, and the slightest touch, or sometimes even a breath of air, would induce most violent tetanic convulsions, which were sometimes so very decided and persistent that the animal would die in a rigid condition and be found in the course of several days dried in an opisthotonous state. Upon testing the action of apomorphine on the motor and sensory nerves, it was found to depress both decidedly, and no evidences of a stimulation of these structures could be discovered; and in a very careful series of experiments on its action on the spinal cord not the least signs of stimulation could be observed, except during this hyperæsthetic condition, and, furthermore, the convulsions occurred in the posterior portion of the body after section of the cord in the upper dorsal region, showing that they were spinal.

These phenomena, in the light of our physiological knowledge, were then inexplicable; for it was seemingly impossible that a drug could act at the same time as a powerful depressor and stimulator of contiguous portions of a structure which is so intimately associated as the motor and sensory portions of the spinal cord; and it was similarly perplexing to understand how it was possible for a drug to cause a state of such profound paralysis, and yet in a little while, and in the midst of it and during a continued absorption of the poison, for a condition of decided stimulation to appear. Hence the utter inability to consistently believe that the paralyzed structures could be so rapidly restored, and a condition of hyperæsthesia exist, or that such a decided nervous depressant of the cord could at the same time possess the power of a stimulant so potent as to cause a hyperæsthetic condition in the midst of profound paralysis, led to the belief that the drug acted on certain hypothetical *spinal reflex-inhibitory centres*, which presumably were similar in their functions to those discovered by Setschenow in the base of the brain, and which had been inferred as existing by recent physiologists, such as Ferrier, Hermann, Bernstein, and especially Foster, who speaks of this function as a resistive power.

Atropine has been found to give rise to similar phenomena, and the action of this drug in the production of the tetanoid symptoms has been carefully studied by Frazer.* This observer found that after the exhibition of a small or rather less than a fatal dose to frogs a slight degree of weakness occurs in the posterior extremities, and motricity becomes gradually more and more impaired, until finally neither respiratory nor voluntary movements occur. Application of various stimuli to the motor and sensory nerves shows that their functions are retained, although in an impaired degree. Some hours afterwards both the afferent and efferent nerves are found to be functionally incapable, although the muscles still retain their irritability. This condition may last for many hours or several days, and the first symptom of a change in animals is noticed in regard to their flaccidity,—the anterior extremities becoming flexed, and their muscles, as well as those of the chest, becoming rigid and decidedly tetanoid. An exalted reflex excitability is now developed, so that a touch of any portion of the skin will increase the spasm in the anterior extremities and chest-muscles, and produce spasmodic movements in the posterior extremities. After a while the same stimulus will induce violent attacks of tetanus, and at a later period the tetanus becomes still more violent, and the duration of the paroxysms is decidedly more prolonged, so that when this convulsant stage is fully developed the animal is in a condition of almost constant spasm. These paroxysms may be elicited at will by simply slightly irritating the skin; but, if frequently repeated, they become shorter in duration and less violent, but reacquire their activity after a proper period of rest.

In this present condition voluntary motion is impaired, although not entirely lost, as the animals are capable of executing some movements.

Frazer now sought to determine the causation of the paralytic-convulsant phenomena, and he therefore first performed a series of experiments in which were

* Transactions of the Royal Society of Edinburgh, 1869, vol. iii. p. 357.

ligated all the blood-vessels going to a single extremity or to the two posterior extremities, when he found that the convulsions occurred in the unpoisoned limbs the same as in the others, and these results he afterwards corroborated by subsequent experiments of the same kind. This, as he points out, clearly indicates that the convulsions cannot be of peripheral origin. Experiments were then performed to show whether they were cerebral or spinal, and, consequently, section of the cord, in a number of animals, was made immediately below the brachial enlargement, with the result of finding that the convulsions occurred in both the anterior and posterior extremities,—thus satisfactorily determining that they were of spinal origin.

Finding, as he believed, that a paralyzant condition coexisted with one of spinal stimulation, he endeavored, by a very novel and ingenious method, to obtain confirmatory evidence by a means which he terms very aptly one of "physiological *synthesis*." With this process he endeavored to imitate the effects of atropine by giving in conjunction a substance that causes paralysis with one that produces spinal stimulation,—the one being methyl-strychnium, which is a paralyzant of the peripheries of the motor nerves;* the other strychnine, which, as is generally supposed, stimulates the motor portions of the spinal cord. The results of these experiments were that he observed phenomena strikingly similar to those in atropine-poisoning, and he therefore believes, after summing up all the evidence deduced from his carefully-conducted researches, that the convulsions are dependent upon a stimulation of the medullæ oblongata and spinalis, and the paralysis, as he previously intimated, to a depression, at least in part, of the efferent nerves; for it is stated that the drug paralyzed the motor nerves, and that the convulsive stage was most marked after the recovery of this paralysis.

If there is a coexistent condition of spinal stimulation and depression of the motor nerves, as above certified, it would be readily explainable how it is that the convulsive stage is put off for such a prolonged period, for it would seem apparent that the reason why impulses reaching a hyperæsthetic cord were not manifest in convulsive moments was simply because the efferent nerves were incapable of performing their function. But a conclusion like this is untenable, since it is invalidated by the results of certain of the above experiments, in which the poison was prevented from going to certain of the extremities; for it is obvious that if the tetanoid stage were postponed because of a paralysis of the motor nerves, the convulsions would occur in these unpoisoned members at once, or at least before they would in other parts of the body: but this is not the case, as has been shown by the more recent researches of Ringer and Murrell,† in which it was found that the convulsions came on in the poisoned legs as soon as in the others. And for a like reason it cannot be due to a depression of the sensory nerves, because irritation of one of these nerves, to which the access of the poison has been prevented, will not give rise to convulsions any earlier in the poisoning than irritation of other portions of the body. It seems, therefore, very clear that both the convulsant and the paralytic phenomena must be of spinal origin, although the depressed condition of both the afferent and efferent nerves would contribute to the latter result; and Ringer and Murrell's experiments fully corroborate the assumption that not only are the convulsions and paralysis due to a spinal action, but that they are both due to depression.

In their researches with this drug, and also with the box (*Buxus sempervirens*) and gelsemium, they have fairly demonstrated that the diminution or even destruction of the "resistive" power of the cord is the sole cause of the tetanus, and that all these poisons are powerful depressors of the reflex function of the spinal cord; and, furthermore, if full doses are given, complete spinal paralysis will follow. Frogs thus poisoned first exhibit great weakness, which gradually deepens, and finally tetanus supervenes. At one period of the poisoning a co-ordinate reflex act or a tetanus can be induced, according to the strength of stimulus,—the weaker stimuli eliciting the former, and the stronger the latter. As the poisoning progresses, the tetanus grows stronger and the normal co-ordinate reflex action weaker, until the animal reaches a condition of almost constant spasm, and finally the tet-

† Medico-Chirurgical Transactions, vol. lix., 1876, p. 389; and Journal of Anatomy and Physiology, 1877, p. 517.

anus itself slowly declines, until nothing but a mere quivering can be induced.

In interpreting the meaning of these phenomena they maintain that at the onset of the tetanus no increased excitability of the cord is present, but that there is one of paralysis, because the tetanus is preceded by the paralysis, and as the tetanus grows stronger co-ordinated reflex action grows correspondingly weaker, indicating that the paralysis of the cord is growing greater, because of the inability of the spinal centres longer normally to co-ordinate reflex movements; and as a consequence of this paralysis the impulses received from the peripheries are no longer confined to certain segments of the cord and reflected or transmuted so as to give rise to a normal reflex movement, but can diffuse themselves along the cord, and by thus affecting a multiplicity of motor cells give rise to a series of movements which we understand as a convulsion; and, moreover, that when the convulsions subside the cord is in a paralyzed condition, instead of possessing at least an approach to the normal irritability, as would seem to be the case if the tetanus were due to a temporary stimulation.

Of all established beliefs there appears to be none which is more universal and more firmly rooted than that strychnine is a powerful stimulant of the spinal cord, and that the convulsions it induces are due to this action; yet recent research has given us some good reasons to change our opinion entirely regarding this action, and to assume, as in the case of the drugs previously mentioned, that the tetanus is also one due to depression. 1st. This drug, as has been conclusively determined, exerts a well-marked influence on the vaso-motor centres,* which it so affects as to cause a decided rise in the blood-pressure; and it was further found by Schlesinger that after section of the cord the rise of arterial tension still occurs, and, moreover, that if a sensory nerve was stimulated in animals thus operated upon, a rise of blood-pressure would be produced; and certain of the experiments of Klapp add confirmatory proof to this. It must therefore be obvious that strychnine, unlike any other drug, affects certain spinal vaso-motor centres; and Schlesinger endeavors to explain this eccentric action by assuming that normally a peripheral vaso-motor impulse can only be reflected or transmuted from the central nervous system after it has reached the principal or presiding centres in the medulla oblongata, but that in strychnine-poisoning the medulla spinalis is so affected that these impulses are no longer conveyed to these dominant centres, but diffuse themselves along the cord, as we have seen in the case of afferent impulses in other forms of poisoning, and by affecting a multiplicity of spinal vaso-motor centres give rise to a general vaso-motor constriction. This theory of Schlesinger's very clearly coincides with the one already advanced by Ringer and Murrell and myself, and, like it, presupposes the existence of a normal "resistive" power in the cord, which is either paralyzed or, at least, held in abeyance by the poison. But in this case the resistive power would seem to be a function of special centres, which may be accurately defined as *spinal vaso-inhibitory centres*, whereas the "resistive" power as observed connected with the convulsions is probably a function of still other centres.

2d. If strychnine thus produces a general vaso-motor constriction, it is certain that there must be a marked condition of anæmia of the spinal centres, and, consequently, when we remember that depression of function in all vitalized structures is the sequence of this condition, it is obvious that the tendency here, in so far as the circulation is concerned, is the very opposite to stimulation.

3d. There can be no doubt, when the testimony of Matteucci,† Moreau,‡ Kölliker,§ Vulpian,‖ and others is considered, notwithstanding the more recent and contrary assertion of Klapp (*loc. cit.*), that strychnine causes a paralysis of the motor-nerve trunks, for it has been noted that these structures are always found to be more or less paralyzed, and stimulus applied to the trunk will either elicit but feeble response or utterly fail; and it is, moreover, clearly determined that the nerve becomes functionally incapable, because when a galvanic current is applied to it, and no movement in the muscle evinced,

§ Virchow's Archiv, Bd. x., 1856, p. 239.
‖ Arch. de Phys., Nov. 1870, p. 125; Martin-Magron and Buisson, Jour. de la Phys., 1860, vol. iii. p. 340.

muscular irritability is found still to be intact if stimulation is directly applied. It has, however, been disputed whether strychnine acts directly on the nerve-structure to bring about this paralysis, or whether it is due to the strain of excessive use. Kölliker believes that the latter entirely accounts for it, because he found that when the nerve is severed it does not lose its functional activity as soon as the intact nerve; but that this conclusion is only partially correct, and that the drug is a direct motor-nerve poison, we have sufficient proof, especially in the researches of Vulpian (*loc. cit.*) and Martin-Magron and Buisson (*loc. cit.*); for it is found that the divided nerve loses its activity, although not so quickly as the intact nerve, and, furthermore, that when excessive doses are given the animals die without any convulsions whatsoever, and the motor nerves are found paralyzed.

In the light of our present physiological knowledge it seems incredible that a poison acting so decidedly as a paralyzant to the motor nerves would act consentaneously as even a more decided stimulant on a continuous structure, such as the motor centres of the spinal cord; and, certainly, if such an action were conclusively proven to be the case, we should have a physiological anomaly so curious as to be beyond precedent. But the keenness of the experimenter has been unable to differentiate to such an extent the phenomena which result from the workings of so intricate and complex a mechanism as the spinal cord as to say decidedly from whence and how all motor impulses originate, and as a consequence he is frequently obliged to assume that a given event is the result of a probable action on a specific portion of the cord; and as an illustration of this fact we have the present drug, which has been assumed to cause convulsions by stimulating the motor centres; but which, when we consider the depressed motor nerves, the apparent loss of a resistive power by which vaso-motor impulses play at will along the cord, and the anæmic condition of this structure and consequent tendency to depressed function, are more probably the result of a depression of the "resistive" power of the cord.

It seems as though we could add indirect though corroborative proof to this by alluding to the results of experiments with the ethyl- and methyl-strychnine compounds. Brown* has shown that these compounds do not induce convulsions, but act like curare, and cause a profound paralysis of the motor-nerve endings. Hence it is believed by some that this new combination has so altered the action of the strychnine on the economy as to destroy its convulsant effects by converting it into a paralyzant instead of a stimulant; but when we consider the effect of strychnine itself on the motor nerves, and assume that it acts as a depressant to the "resistive" power of the cord, it seems evident, as Ringer and Murrell suggest, that when the strychnine is converted into an ethyl-compound its physiological action is not reversed, but only its chemical affinities so modified it that it affects the motor nerves relatively more powerfully and the spinal cord relatively less. As a consequence, the reason why convulsions do not occur is either because of the feebleness of its spinal action or because the paralysis of the motor-nerve peripheries becomes so rapidly advanced that they are unable to transmit motor impulses when the cord has reached the convulsant stage, or both.

Curare and certain other well-marked spinal depressants are sometimes observed to cause convulsions, which are usually preceded by paresis, more or less marked. Considering the above testimony, it is readily conceivable how any spinal depressant may give rise to convulsions; but if it is assumed that these phenomena are due to stimulation, we have a formidable difficulty to contend with in any attempt to explain how a drug can paralyze the cord and in the midst of it act as a stimulant sufficiently powerful to induce convulsions. The assumption of the existence of this "resistive" power of the cord—which I think can be better expressed by designating the portions of the cord in which this resistive power resides as the *spinal reflex-inhibitory centres*—makes an explanation of the *modus operandi* of causation of convulsions by spinal depressants easy, and effectually answers what has been for a long time a very perplexing question.

Strychnine, however, gives rise to convulsions at once, while the other drugs first induce a condition of paralysis. But Ringer and Murrell, in their masterly re-

* Trans. Royal Society of Edinburgh, xxv., part i. p. 151; and Journal of Anatomy and Physiology, 1868, vol. ii. p. 224.

searches, have given us an explanation of this in the fact that the difference in these results is probably dependent upon the degree to which a given drug affects reflex action; for, while some of them diminish it very materially, others, again, affect it little or not at all. They therefore assume that in strychnine-poisoning reflex action is unimpaired, while the resistive power alone is annulled; but in atropine-, box-, and gelsemium-poisoning reflex action is affected also, and, as a consequence, modifies the convulsant phenomena, both in the time of their occurrence and in their violence. In other words, the relation existing between the degree of the effect on reflex action and the resistive power of the cord determines the time and degree of the paralysis (if this is present), the early or late appearance of the convulsions, as well as the degree of their violence.

MEMBRANOUS CROUP TREATED BY PILOCARPIN—CHANGE IN THE COLOR OF THE HAIR FROM THE USE OF PILOCARPIN.

BY D. W. PRENTISS, A.M., M.D.,
Professor of Materia Medica and Therapeutics in the National Medical College, Washington, D.C.

MUCH attention has been recently attracted to the use of pilocarpin in diphtheria by the report of its favorable action in that disease by Dr. George Guttman, of Cronstadt.

Dr. Guttman obtained very favorable results in the treatment of a large number of cases. His observation was to the effect, not that the drug exerted any specific action over the disease, but that it apparently loosened and softened the false membrane by its action upon the secretion of the mucous membrane, so that the false membrane was more easily expelled. His report was followed by one from Lax, who treated ten cases of diphtheria by pilocarpin exclusively, all of which recovered. Six of these were very severe, and in two death was expected nightly. Still more recently, Dr. Ed. C. Wendt, of New York, reports three cases (*Medical Record*, April 9, 1881) in which, after other remedies had failed, pilocarpin was given and recovery followed. On the other hand, however, Dr. Neumeister has published an account of twenty-eight cases of diphtheria treated by pilocarpin with rather unfavorable results. Five of the cases were adults, and the others children. The adults seemed to be influenced favorably; but in the cases of the children thirteen out of the twenty-three died, and in eight bad effects of the pilocarpin were observed. Neumeister's conclusion is that pilocarpin is a dangerous remedy with children, and that its value in diphtheria is not sufficient to justify its use. In a disease so fatal as diphtheria,—especially that form known as *membranous croup*,—any remedy which promises to avert the usual distressing termination is welcomed with avidity by the profession. In the question under consideration the preponderance of evidence seems to be in favor of pilocarpin. The success of Guttman, Lax, and Wendt has been much more marked than that of Neumeister; nor have they observed any of the unfavorable effects claimed by Neumeister to follow its use. Undoubtedly pilocarpin is a powerful drug and capable of doing mischief, but my observation coincides with that of the first-named observers,—that its effects can be regulated and controlled.

The importance of the subject has influenced me to report the following case, in the hope that it may be an additional inducement to others to give it a trial.

Chas. S., aged 14 months,—a healthy, well-developed infant, of German parentage,—was fretful and complaining for several days previous to June 9, 1881; voice and cough hoarse. June 9 the voice was lost.

June 10, P.M.—First saw the patient. He was lying on the bed, restless, but objected to being disturbed; breathing loudly stridulous, voice entirely suppressed. On examination of the throat, the entire fauces were found covered with an ashy-white false membrane. Very little febrile disturbance. Prescribed a mixture of chlorate of potassium and tincture of chloride of iron internally, and a one-per-cent. solution of carbolic acid to be applied locally; also, in case the dyspnœa should increase, an emetic of turpeth mineral.

June 11, A.M.—Patient worse; dyspnœa and restlessness have increased; the emetic had not been administered; gave a dose (25 centigrams) while I was at the house. It caused free vomiting, with expulsion of several pieces of false membrane, and was followed by great prostration. So much difficulty was encountered in mopping the throat that it was discontinued, as was also the iron mixture. The following prescription was ordered:

℞ Pilocarpin. hydrochlor., 0.02 gram;
Sacchari lacti, 2 grams.
Fiat in chart. no. x.
S.—One every hour.

Directions to repeat the turpeth mineral if necessary. Milk punch *ad libitum*.

June 11, P.M.—Condition about the same as in the morning.

June 12, A.M.—Condition no worse. Emetic of turpeth mineral during night. Dose of *pilocarpin* doubled.

June 12, P.M.—Patient better; has slept most of the day; stridulous breathing less marked; more cough, and cough looser; sweating and salivation very free; dose of pilocarpin reduced to the original amount.

June 13, A.M.—Still better; passed a comfortable night, sleeping all night; stridulous breathing gone; false membrane has disappeared from the fauces.

June 13, P.M.—Still improving; cough troublesome, but loose; aphonia still present.

June 14, A.M.—Still improving; slight return of the voice in crying.

June 15, A.M.—All the symptoms decidedly better; appetite returning.

June 18.—Since last record the improvement has been steadily progressive. No longer any sign of false membrane, and the voice has returned. The bowels, however, are very loose. Pilocarpin discontinued, and a diarrhœa mixture ordered.

When I first saw this patient I considered the prognosis very unfavorable,—I might say almost hopeless. The child was in that state so familiar to us in advanced membranous croup. The result can hardly be attributed to the two doses of turpeth mineral taken, although portions of false membrane were thus thrown out. In numbers of other cases I have used this emetic, and never but once with favorable result. In the successful case referred to, the diphtheria had commenced in the fauces and extended to the air-passages. A complete cast of the trachea was twice expelled under the action of the yellow sulphuret of mercury. In the case now under consideration this did not occur. The improvement followed the administration of the pilocarpin, and was most marked when the action of that drug upon the system became decided. Its mode of action seemed to be by loosening and softening the false membrane, so that it was easily expelled by the act of coughing. The salivation and sweating produced did not distress the little patient, and were easily controlled. It caused a marked tendency to sleep.

A word in regard to the administration of jaborandi.

The most economical as well as the least elegant form is that of infusion. This, however, in dose of from three to six grams of the leaves is sufficiently certain in its effects. The fluid extract of jaborandi is a more concentrated form of the drug, and, if freshly prepared, is reliable in doses of four grams. The solid extract may also be used in cases where it is desirable to give the medicine in pill form. But undoubtedly the most elegant as well as the most reliable preparation is the alkaloid pilocarpin, either as the hydrochlorate or the nitrate. Pilocarpin is the active principle. In using the leaves, the activity or efficient dose will depend on the proportion of the alkaloid contained, and this varies with different specimens. The best jaborandi comes from Pernambuco, Brazil, and is the product of the *Pilocarpus pinnatifolius*. Since the development of an increased demand for jaborandi, an inferior article has been put upon the market from the Argentine Republic, consisting of the leaves of another species of pilocarpus, which contain a smaller proportion of the alkaloid. The same uncertainty of strength would apply to the fluid and solid extracts. Their strength in pilocarpin would depend upon the quality of the leaves from which they are made.

In many cases where we are called upon to administer this drug the stomach is irritable and will not retain medicine. The pilocarpin salt is soluble and entirely unirritating when given hypodermically, and in the dose of one centigram (one-sixth of a grain) acts promptly, producing full diaphoresis and salivation. For hypodermic use it is best to order it in powders,—one centigram each,—and dissolve in water at the time of using, repeating the dose hourly until the desired effect is obtained. As a general rule, solutions of all alkaloids are objectionable, for the reason that they are readily decomposed. In treating young children it is often difficult, and sometimes impossible, to administer the infusion of jaborandi, or even the fluid extract. The pilocarpin may be given in dose of from one to four milligrams (one-sixtieth to one-fifteenth of a grain), in powder with sugar, and is pleasant to the taste. I can, however, see no advantage in the combination offered by Dr. Guttman,—with pepsin and hydrochloric acid. It is best, unless there be good reason to the contrary, to keep prescriptions simple, especially where we desire to observe the action of a new remedy. For this reason I think the prescrip-

tion given above preferable to that of Dr. Guttman.

CHANGE IN THE COLOR OF THE HAIR.

In a recent article (*Philadelphia Medical Times*, July 2, 1881) I reported a case in which a remarkable change occurred in the color of the hair of a patient while under treatment by pilocarpin. Having this in view, I took a specimen of the child's hair in the present case, in order to compare with the color later and see if any change took place. The case seemed at first so hopeless that the specimen was not taken until June 17, when the pilocarpin had already been administered for six days. The second sample was cut from the child's head on June 27, ten days later, care being taken to select a place corresponding to that from which the first sample was taken. The difference between the color of the two is not great, but is sufficiently marked to be distinct. The first specimen is a light brownish-yellow, and the second is a shade darker. I did not anticipate, in this case, any change in the color of the hair, because I did not think the pilocarpin had been taken long enough. The specimens, however, show a decided change, and I record it for what it is worth.

COMPOUND DISLOCATION OF ANKLE WITH FRACTURE OF MALLEOLI—EXCISION OF JOINT—RECOVERY, WITH USEFUL LIMB.

BY H. R. WHARTON, M.D.,

Assistant to Professor of Clinical Surgery, University of Pennsylvania.

ON the evening of October 4, 1880, I was requested by Prof. Ashhurst to see, for him, the following case in his ward in the University Hospital.

J. M., aged 15 years, while playing on some iron railings, fell, his left foot being fixed, and sustained a severe injury of the ankle-joint.

On examination of the injured part I found a complete dislocation of the tibia and fibula to the fibular side, the bones protruding for two inches through a transverse wound a short distance above the position of the external malleolus; the internal malleolus was entirely detached from the tibia, and remained in contact with the internal lateral ligament of the ankle-joint; the external malleolus was fractured, and only adherent to the fibula by periosteum. The foot was twisted to the inner side; the surface of the astragulus articulating with the tibia was uninjured, and exposed in the wound. The color and temperature of the foot were good, and on examination the anterior and posterior tibial arteries were found to be uninjured.

In an injury of the ankle-joint of such severity, three methods of treatment would naturally suggest themselves: first, reducing the dislocation, having detached the loose fragments of bone; second, amputation of the limb; third, excision, complete or partial, of the bones.

The first method of treatment, I thought, might be set aside by the condition of the parts; compound dislocation with fracture, with the consequent dangers from tension after reduction. The second, amputation, I thought unquestionably the safest mode of treatment as regarded life, but it would have had the disadvantage of leaving the patient without a useful limb. The third method, excision, seemed to me, under the circumstances, the best, giving the patient a chance for a useful limb, and diminishing the dangers which follow the reduction of compound dislocations without excision.

The age of the patient and the uninjured condition of the arteries were important elements in favor of excision over amputation. The patient was etherized, when, having slightly enlarged the wound

downward, I divided the periosteum and separated it from the bones, and with a chain-saw removed one and a half inches of the tibia and fibula, leaving a small portion of the tibio-fibular articulation. The detached internal malleolus was now removed from the internal lateral ligament, to which it was adherent, and the foot brought into position without difficulty. The astragulus was not excised, as it was uninjured, and there seemed abundant room for drainage and relief of tension. The sawn ends of the bone were rounded with forceps and a drainage-tube introduced into the wound, which was closed with silver wire sutures. The wound was dressed with a laudanum dressing, and the limb placed on a bracketed wire splint, so that subsequent dressings could be accomplished without disturbing the parts.

The case after operation was under Prof. Ashhurst's care; the wound healed by adhesion, except at the lower portion, where the drainage-tube protruded. The tube was removed about the tenth day, and the wound remained open and discharged slightly for several weeks. Several abscesses appeared on the fibular side of the foot, which were opened and continued to discharge for some weeks. The leg was kept on the wire splint for six weeks, by which time all sinuses left by the abscesses had healed. It was now removed from the splint and a plaster-of-Paris dressing applied, which was retained for four weeks.

On examining the parts after removing the plaster dressing, three-fourths of an inch shortening was found to exist in the injured limb; the configuration of the joint was not much altered, there having apparently been a production of new bone near the site of the malleoli; the patient also had a fair amount of motion in the ankle-joint.

The patient was discharged from the hospital in January, 1881, walking with a slight limp, and a month later was seen in excellent health, wearing a high-heeled shoe, but walking without any lameness whatever.

1407 Locust Street.

The Last of Chian Turpentine.—Mr. Hulke (*Lancet*, June 25) reports a number of cases treated by Chian turpentine in the cancer ward of the Middlesex Hospital, none of which were benefited in the least.

TRANSLATIONS.

Temperature of Contracting Muscles of Mammals.—A summary of Dr. R. Meade Smith's interesting article on this subject (*Du-Bois Reymond's Archiv*, May, 1881), is as follows. The subject of investigation is divided into four sections:

I. The changes in temperature of the venous blood coming from contracting muscles.

II. The temperature of normal contracting muscle.

III. The share of the blood-current in the production of an increased temperature in tetanus.

IV. Heat-production in muscles with artificial circulation.

I.—The Changes in Temperature of the Venous Blood coming from Contracting Muscles.

In the first ten or fifteen seconds of a strong irritation of the crural nerve, the temperature may remain stationary or even sink from the initial arrest of the blood-current in contraction, then the temperature commences to rise rapidly, and in the first two minutes attains nearly or quite its maximum height. When the tetanus lasts longer than two minutes the temperature falls or may rise a little higher, but extremely slowly. At the end of the tetanus the temperature may continue to rise, even when the blood coming from the relaxed muscle is warmer than that flowing to it. This may be due either to a continued heat-production in relaxed muscle or to the fact that since the blood flows more slowly it has longer time to be heated up to the temperature of the muscle. In all instances the temperature of the venous blood reaches very slowly its height before the tetanus. The venous blood may become as much as 0.6° C. warmer than the arterial during a tetanus, and this, too, independently of the difference originally between the two temperatures: *e.g.*, when a second tetanus follows the first before the heating effects of the first have passed off, and while the venous blood is still warmer than the arterial, we have still an increase of temperature.

By estimating the quantity of blood flowing through the muscles in tetanus we have determined that at least as much as 25 to 75 heat units are removed by the venous blood from the muscle.

II.—The Temperature of the Normal Contracting Muscle.

The muscle mass at rest is usually 0.5° C. cooler than the artery, from loss of heat through the surface. The entire muscle is not of a uniform temperature, although in alterations of temperature all portions of the muscle are similarly and simultaneously affected.

a. The temperature of the muscle in different degrees of stretching.—The maximum temperature and the rapidity with which it is attained are, in the living, warm-blooded muscle, entirely independent of the amount of work done, thus contradicting the statement of Fick for the frog's muscle.

b. Relationship between changes of shape and temperature according to length and strength of irritation.—The changes of shape and of temperature cannot be said to be closely connected, since when we have the greatest contraction the (heat-production) increase of temperature may be slighter than in a weaker contraction: the same holds true as to actual heat-production. We may say that a stronger contracted muscle loses more heat. The muscle and venous temperature are invariably affected in the same manner. Therefore the excess of venous over the arterial temperature corresponds to the higher temperature of the muscle.

The temperature, and equally probably the development of heat, increases with the irritation, whether a corresponding increase occurs in the degree of contraction or not: so the generally admitted theory that the change of shape of the muscle and the development of heat are only different expressions of the same tissue-change, can no longer be admitted. We are not, however, thereby compelled to suppose the existence of two entirely distinct processes brought about by different nerves.

Ordinarily the muscle loses its heat-producing power before it loses its contractility. We may have a series of contractions of equal extent with a constantly diminishing heat-production in each.

"Contracture" differs from tetanus in the fact that in the former we have a rapid fall of temperature instead of the rise which occurs in the latter.

We may have an irritation strong enough to produce a decided contraction, and yet not strong enough to produce an elevation of temperature, while the results with increasing irritations coincide with those of Heidenhain as to the frog's muscle, that the development of heat grows more rapidly with an increasing irritation than the contraction.

c. Relationship between the maximal temperature of the fresh and fatigued muscle.—The experiments under this section show how variously a muscle will behave as to heat-production after prolonged exertion. They go to show what a very slight connection there is between the two results of nerve-irritation, viz., the contraction and the heat-production, contradicting Heidenhain as to the fixed relation between heat-production and fatigue.

d. The after-working of the irritation on the actual temperature.—Heat-production may continue in a relaxed muscle, though this is not the rule.

III.—The Share of the Blood-Current in the Production of an Increased Temperature in Tetanus.

a. Comparison of the temperature of tetanized muscle in the bloodless and normal condition.—In the bloodless condition only a slight share of the chemical change could be attributed to the oxygen of the blood remaining in the vessels, as time was allowed for it to become deoxygenated. During a tetanus which does not last more than two minutes in a muscle deprived of its circulation, we can have as great an increase as occurs in the normal muscle. There is, however, a slighter degree of actual heat-production. After the second minute of tetanus the increase of temperature in the bloodless muscle becomes a fall, and by the fourth minute all the increase of heat may be lost, the capability of developing heat being lost from the modification of some part of the irritable apparatus.

The influence of the continually renewed blood on the heat-producing tissue-change is positively proved by the length of time the process continues in normal muscle compared with those removed from the circulation. When the blood-stream is closed in the middle of a tetanus there is a sudden fall of temperature, and again a rise when it is reopened. If, however, at the time of closure the irritation is increased, we have a rise instead of a fall. The capability of executing work is influenced by the closure of the blood-stream in the same way as the temperature.

b. The action of curare on muscle temper-

ature.—Here we can produce contraction with acceleration of the circulation. There is here even in rest a constant upward tendency of the thermometer: the muscle may become warmer than the artery. This occurs when the circulation is mechanically retarded through the muscles, while each new injection of curare causes a fall of temperature. On direct irritation of the muscle we have a rapid increase of temperature, which may last several minutes after the tetanus, as seen in the thermometer in the muscle. The increase is not so great or so rapid as when the nerve is irritated without curare. The thermometer in the vein after the tetanus shows a rapid fall. When the nerve is irritated in curare experiments we may have a fall of temperature by action on the vaso-constrictors.

c. On the cooling influence of the blood after reduction of the pressure by bleeding or section of the cervical cord.—After bleeding we have an increase of arterial temperature and an increasing inability of the muscle to contract through a long period: nevertheless we still have a decided increase of temperature in the venous blood during a tetanus, as was also the case after section of the cervical spinal cord.

IV.—Artificial Circulation through the Muscle.

Here a rise of 0.16° C., was noted even when the arterial fluid was 0.76° cooler than the muscle.

This fact opens a very promising future for direct calorimetric studies on contracting muscles, as their irritability may be preserved for several hours.

Malarial Poisoning in Young Children.—In a clinical lecture on this subject (*Revue de Thérap.*, 1881, p. 260) Dr. Jules Simon says that while intermittent fever, especially of the severe type, is often difficult of diagnosis in the adult, it is much more so in the infant, both because its signs are different and because these may vary with the age. In the infant under two years of age the malarial poison does not show itself with the same regularity as in the adult. The quotidian type is that oftenest observed, and frequently by day as well as by night. In the latter case the symptoms are the same as those of ordinary fever from sore throat or digestive trouble. There are certain signs, however, by which it may be recognized. At whatever moment the attack begins, it is sudden. The cold stage comes on so quickly and is of such short duration that it can scarcely be recognized unless one is prepared for it; the extremities are like marble, the pulp of the fingers shrivelled, the matrix of the nail blue, the eyes sunken, the cheeks and the end of the nose pale. Then follows the feverish stage for an hour or two, terminating by a short stadium of perspiration, affecting particularly the neck and chest. When the attack comes on at night, the child wakes suddenly, crying at an unaccustomed hour, and by the time he can be examined is already in the hot stage. For this reason it is easy to mistake the infant's condition for some commencing eruptive fever, dyspepsia, dentition, etc. The tongue, however, will give some indication if examined, for, if the trouble is malarial, a semi-lunar patch of rawness may be observed about its edge.

In the irregular forms the child, without actually having any fever, may be forlorn and refuse to nurse at one time of the day, taking the breast again at a later period. These infants cry if pressed upon over the head, eyes, or ears, because they suffer with multiple neuralgia. At other times only a slight sweating is noticed, or a little diarrhœa. Sometimes quinine must be given in doubtful cases before the nature of the malady can be made out.

Infants at the breast are not free from danger regarding the chronic poisoning of malaria, which develops a cachexia from which many succumb. The child's face assumes a waxy hue, he becomes thin, his legs and face become puffed, the spleen is hypertrophied, sometimes to a considerable degree, and death often occurs in syncope, convulsions, or coma. If the infant survives, a treatment extending over years may be required to restore him to perfect health. The pernicious forms are similar to those observed in adults.

In children from two to six years of age, the attacks are more marked, if possible; they are tertian or double tertian, and are more apt to occur during the day than during the night. They may simulate typhoid fever or meningitis. Simon also mentions one curious case presenting torticollis, apparently dependent upon Pott's disease of the spine, only it returned daily at the same hour, and disappeared under the use of quinine. At other times persistent bronchitis may be observed, rebel-

lious to all medication, and only yielding at last to quinine. Now and then rachialgia of a periodic character is observed, with congestion of the meninges, causing atrocious sufferings, in the form of fulgurating pains in the limbs, with contraction.

The prognosis is serious, except in light cases. Sometimes quinine has to be given for years. The pernicious form is always fatal.

Sulphate of quinia is of course the treatment in all these cases. Up to two years of age ¾ grain to 2¼ grains may be given in little granules of ⅙ grain each, which the infant can easily be made to swallow. Enemata containing three to four grains may be administered, or the same amount by inunction. In the pernicious forms the following solution is to be given in the space of an hour:

℞ Quiniæ sulphat., gr. iij ad ivss;
Tr. opii (Sydenham.), gt. j;
Sol. sacch. alb., gtt. c.

In older children, from two to six years, the dose should be three to four and a half grains in sweetened glycerin with syrup of tartaric acid, and when the attacks are violent three-quarters of a grain may be given every hour until toxic effects are produced. If the child refuses to take the solution with glycerin, the quinine may be given in coffee or in one-sixth-grain pills in some confection.

In the chronic malarial poisoning of infants at the breast, change of air, with the administration of iron and arsenic to the nurse, may be prescribed. Above two years the treatment must vary with the case. Sometimes coffee may be given, also maceration of quinia; at other times arsenic, phosphate of lime, hydrotherapeutics, sea-bathing. Purgative and all other enfeebling treatment must be avoided.

Late Hereditary Syphilis.—At a recent meeting of the Société de Chirurgie (*La France Médicale*, 1881, p. 675) Dr. Lannelongue remarked on the osseous troubles which show themselves during the later stages of hereditary syphilis, and which, according to their origin, manifest themselves as subacute inflammation of the bone and as periostitis. The enlargement of the bone assumes the form of periostoses and hyperostoses, and it may result in augmentation of volume and also of length. The seat of the hyperostoses is the diaphyseal region in the neighborhood of the apophyses,—a point where nutritive activity is at its highest. From this region this neoplastic action is propagated along the diaphyses, following a central or peripheric course. It may include as much as ten to fifteen centimetres of the length of a long bone. The ultimate evolution of these hyperostoses gives rise occasionally, as in the adult, to abscesses and exfoliation of bone. It leaves behind it in every case singular and permanent deformities, which treatment is powerless to cure. These deformities present a peculiar physiognomy easy to recognize. The bones most frequently affected are the tibia, ulna, radius, femur, and humerus. The mixed treatment, thoroughly carried out, cures these cases when early seen. When the deformity has actually occurred, only the prevention of further extension can be hoped for.

A New Exhilarant.—Dr. Luton, of Rheims (*Bull. Gén. de Thérap.*, vol. c., 1881, p. 254), calls attention to the curious exhilarant properties of a mixture of tincture of ergot with phosphate of sodium, which he recently discovered by accident. The effects of this mixture can best be compared to those of nitrous oxide gas, but are of a more permanent character, lasting from an hour or two to several days. Patients show signs of hilarious but slight intoxication. Saturnine and melancholy individuals laugh, joke, and display the utmost gayety. Dr. Luton considers the medicine to possess a certain value in cases accompanied by melancholia, in the neurotic algidity of hysterical persons, and in the anæmia of chlorotics. A convenient formula is the following:

℞ Tincturæ ergotæ, ℥j ℈j;
Sol. sodii phosphat. (10 per cent.), f℥iv.

Mix in a quarter of a tumbler of sweetened water, and take at one dose before eating.

Locomotor Ataxia.—Prof. Pitres, in a lecture on this subject (*Revue de Thérap.*), formulates the following statements. 1. Sclerosis of the posterior columns always begins with sensory disturbances. 2. The painful symptoms almost always present a peculiar aspect, which allows an early diagnosis to be arrived at (their fulgurant, intermittent, irregular occurrence). 3. The pains may be located in any part of the body (limbs, face, viscera, vertebral column). 4. They precede the motor disturbances by months or years. 5. They may for an indefinite period constitute the only symptoms of ataxia, which in this case deserves the designation *tabes*.

EDITORIAL.

EYESIGHT IN THE PUBLIC SCHOOLS OF PHILADELPHIA.

THE report of the committee of the County Medical Society on examination of the eyes of children in the public schools of Philadelphia, which appeared in our last issue, contains facts and conclusions so interesting and important as to merit the careful attention, not only of physicians, but also of the intelligent public generally. Too little importance has heretofore been attached to the conditions of study in relation to the preservation of eyesight, and, although the attention of parents and instructors has in recent years been drawn more and more to the subject, yet, from the necessity of the case, this interest has been that of inquiring ignorance asking for that guidance which it is clearly the duty of the medical profession to furnish to the community at large.

The desired information has now been at least to some extent obtained, and, although the investigations of Dr. Risley's committee were not extended over as great a number of cases as might have been desired, yet, from the results of examination of some twenty-four hundred eyes in children attending all grades of the public schools, a fair estimate may be made of the conditions of eyesight prevalent among the school-children of Philadelphia.

The conclusions drawn are to some degree unexpected. Thus, for example, it has been generally thought that improperly lighted school-rooms were perhaps the chief factor in the production of weak eyes; and more and more attention is being paid to this subject by the school authorities. But, as Dr. Risley points out, other causes are also at work, among which are the habit of reading and study carried on at home to an excessive degree and under more or less unfavorable and injurious conditions; the custom of sending children to school at too early an age (which the investigations of the committee show to directly favor the occurrence of defective vision), and chiefly the pre-existence of more or less abnormal eyesight. To this, perhaps, may be added the use of books improperly printed on poor paper and with defective type. While we believe the books in use in our schools are usually of the proper kind in this respect, yet the prevalence and popularity of those cheap but abominably printed editions of standard authors must unquestionably exert a pernicious influence on the eyesight.

The conclusions of the committee—to the careful perusal of whose report we urge all medical men who may be personally or officially connected with the mental training of our citizens of the future—point directly to the following measures which should be carried out if the subject of eyesight in the public schools is to receive the attention it demands.

1. The proper lighting and seating of our schools should receive the earliest attention, with the view of remedying well-known existent defects and preventing for the future those errors in architectural construction which exist in present school-buildings.

2. Children should not be permitted to enter school at a too early age.

3. *A careful examination should be made of the eyes of all children on entering upon school-life, and such precautions should be taken as to correct or prevent injury to the eyes from study.*

4. Parents should be warned of the harm and injury which may result from over-study and especially from excessive reading at home, and they should also be told to take heed to the conditions of light

and position occupied by children during their hours of reading and study.

It is the duty of the medical profession to urge these views on the community at large as occasion offers, with the hope of influencing public opinion.

CORRESPONDENCE.

LONDON LETTER.

SO far as unwonted heat will permit, we are all in expectation, and the bustle expectation gives rise to, about the forthcoming International Medical Congress,—getting ready, but impeded by prostrating tropical heat. It is expected to be a monster affair, and units are coming from all corners of the earth, till aggregated units will constitute hundreds. So far the arrangements seem to be well laid out; but what the actual accomplished results will be, time will tell. Of course, already there are heart-burnings and envyings: somebody is more prominent than he ought to be, while somebody else is unduly thrown into the background who feels that he is an ornament to the profession who ought to be made the most of. It is rather humiliating to think how small humanity can be at times, how little matters can perturb the mental processes of even educated men. Granting a prominent position can be secured, how does the aspirant know that this is not going to be a misfortune rather than an advantage, if the execution is not thorough? This anxiety for prominence amidst the mediocrities is one of the curious features of human middlingness,—that it has not the wit to remain in obscurity, but moves its little macrocosm to place it where its incapacity will be only all the more conspicuous. Of course there are also a number of most competent individuals engaged in it, who will "pull the thing through" despite incapable colleagues. The promise of attendance by foreign celebrities is most encouraging for a capital meeting. With Sir William Jenner, K.C.B., at the head of English medicine, the home section will hold its own successfully against all comers. If our capricious climate will only just be accommodating, I think we will get through the ordeal fairly successfully.

In medical circles here great interest is felt in the progress of President Garfield towards convalescence after his most serious accident. The prevailing impression is that the medical part of the matter has been conducted with consummate skill, reflecting the very highest credit upon American medicine and surgery. Of course all recognize the admirable constitution and indomitable courage of the patient, which are of so great moment in such an injury, and without which all therapeutic measures would be of little or no avail. The absence of high fever and of considerable peritonitis is a feature of the case as unusual as it is interesting. The published temperatures in our papers have been curious instances of error, which must occasion great perplexity in the minds of those who are more interested in than familiar with medical details. For instance, one day when the wounded man was reported to be doing well, the temperature was given as 106.6-10°, which certainly was a mistake of the printer or the telegrapher; but a day or two later, when further satisfactory progress was announced, the temperature was stated to be 109.9°. Now, this last is a temperature which is regarded as incompatible with life, though one or two isolated cases are on record where such a temperature has been recovered from. But as to the ordinary experience of humanity, the first temperature indicates a very grave condition, while the second would necessitate the most active steps being taken to secure the completion of that voluntary offering intended to provide for his wife and children if the worst should be realized. Of course no material harm is done to anybody by such careless errors, but there is enough incorrect information about, without adding to it. Much interest, too, is felt in the means which have been adopted to lower the temperature of the room during this terrific heat-wave which we all are experiencing. Such measures have an interest for every medical man, and will be made an addition to the armamentarium of every practitioner in hot weather. The difference of a degree or two is of moment in critical cases, and every one who has had personal experience of a temperature over 105° Fahr. knows well enough the significance of that degree or two as regards the subjective sensations. The whole case, indeed, is most instructive. One was taught that wounds of the abdomen were almost certainly fatal; and yet here is a patient scarcely feverish, and free from any serious peritonitis, who carries in his abdomen the comparatively large bullet of a "California bulldozer" fired at a short distance. As said before, the whole case reflects much credit upon American medicine; and the lesson ought to bear lasting fruit, even if no heroic medicinal measures were adopted. The moral control of the case has been, of course, a very important matter; for if a patient seriously ill is surrounded by a number of persons, all of whom speak to him and treat him as if he is dying—well, he very likely will die. This is a matter not nearly sufficiently estimated, and many a patient owes his life to the disposition of his medical attendant. It is not merely enough for a doctor to visit his patient and take careful note of how he is; something more is desirable; viz., he should lend the patient a little of his

own cheerfulness. His advent should be looked for, and he should be welcomed as bringing good fortune with him. There never was a consultant in large and successful practice who was not of a cheerful disposition. For is not the indirect encouragement given to a patient by a cheerful demeanor and an inspiriting tone of voice often one of the most vitally important factors of the management of the case? On the other hand, certain relatives are death to the sick. If Peter Featherstone, in "Middlemarch," had had an ailment which permitted of recovery, or even of a temporary rally, he would have had no chance with his brother Solomon, or his sister, Mrs. Waule, to say nothing of his nephew, young Cranch. With three such enlivening individuals as allies, grim Death would carry off the best of us, if ill. So it is with other persons when ill. If they are surrounded with cheerful persons, they have a fair prospect of pulling through. But let them be encircled by moping or dolesome relatives, and their chances fade out quickly. In old Peter Featherstone's case, of course these relatives were furthering their own ends by thus depressing the little life that was left to their unamiable relative, whose very breath they seemed to grudge. But in the majority of instances these "kill-joys" are such unintentionally, and not by design. They are people of an unhappy temperament,—oppressed, too, with a sense of seriousness at the emergency very often. But they are murderous all the same. Some medical men, too, have a depressing temperament and manner with them which is lethal to their patients in any emergency. There is one such man well known in London. It is said of him, "But his patients all die!" Yet he is an able man, as is demonstrated by his written works. He is also an F.R.S. He is a finished gentleman. But he is not cheery, and he is only partially successful in proportion to his intellectual deserts. A very fashionable physician is, on the other hand, a cheery man; his tone of voice and accent are encouraging; the patient feels the better for seeing him, and naturally is glad to see him. Such a man is a godsend to patients when life and death are nearly evenly balanced and the tones of a voice may make all the difference. No wonder he gets large fees, for he deserves them. Stories are told of large sums being given him merely to visit a dying man where no hope of any improvement was entertained, but merely to cheer him with a chat. Such a presence in a sick-room breathes life into a patient, inspires him with hope, and results in his recovery, if that is among the list of the practically attainable. An observant, thoughtful medical man always looks to the individuals around a sick person, and weeds out the undesirable ones. Of course they object. But, fortunately, the fitness of relatives for nursing an invalid is an exploded notion. The tie of blood does not constitute a qualification for a sick-room, and though such frank expression may be an offence to certain personages who like to make their way into a sick-room, it is perfectly justifiable. Why in the name of common sense has a sick person to die because some gloomy-minded individual determines to nurse him? The growth of professional nurses is largely fostered by this constitutional unfitness of temperament for nursing on the part of some relations. The doctor can secure a cheerful nurse, fortunately, for nurses can be got on demand. But persons must put up with their relations; there is no changing them! And, if unfortunate enough to be seriously ill, they must take their chance with them. These croakers flock to the sick-room as gloomy as ravens. They resent any hint that they are not felt to be essential. They have come to fulfil a duty; and they are going to do it. Yes; and, if the doctor cannot succeed in getting rid of them on some pretext or other, they will persist in doing their duty till the funeral is over. Family affection is a beautiful topic for the sententious, but in a sick-room it is often an unmitigated misfortune for the sick person. The middle-aged woman, whose face is the reflex of her thoughts, and who is given to speak a word in season, whose bombazine dress is an outward indication of her unfitness to be near a person who is seriously ill,—she is simply a death-warrant incarnated. I respect her motives, but I question her suitableness for her self-elected mission. A more dangerous association for a case of serious illness it is difficult to imagine. Such a female on the premises darkens the prognosis wofully. If she cannot be got rid of, the patient's existence is merely an affair of days. Get her away, and a cheerful nurse with a pleasant voice and a light hand in her stead, and the patient's prospects immediately brighten. A pious widow with dyspepsia and strong religious convictions is a ghoul when illness is about. She sucks the life out of an invalid like a moral vampire. As life ebbs she is sustained, and when the invalid has passed the portals of another world she goes away edified, strengthened, and encouraged in her murderous mission, fully prepared to extinguish the life of any number of relatives, if ill-luck should prostrate them on a sick-bed. Yet she is devoted to her ghoulish mission. She is as convinced of her moral right to intrude herself upon her dying relatives as were old Peter Featherstone's "blood-relations, who naturally manifested more their sense of the family tie, and were more visibly numerous, now that he had become bedridden." Their obtrusiveness was not to be snubbed, and Solomon was spokesman for near kith-and-kin when he replied, on being ordered out of the room, "I shall be down-stairs, brother, whether or no. I shall do *my* duty, and it remains to be seen what the Almighty will

allow." Now, such a family demonstration may seem very absurd in your country, but it would not be in any opposition to a North-country experience, when serious illness developed. Ties of blood then became visible which ordinarily were occult; and when the funeral finally arrived, the group entitled to sit in the bedroom where the coffin lay represented the furthest development of the blood-tie, in many instances only known to exist by these periodical appearances when the undertaker's sad task called the relatives together. A sad demeanor, a suppressed manner, funereal tones, are appropriate enough when the opportunity of showing respect to a distant kinsman by being present at his obsequies calls them forth, and then are harmless; but if allowed previous to this event they are decidedly homicidal. Nevertheless, it is sometimes part of the duty of a consultant to banish certain objectionable individuals from a sick-room; and very injured the ejected look when the sentence is carried out. At other times it is not moral but physical or intellectual unfitness that constitutes the bar, —a heavy foot, a clumsy hand, an officious manner, a harsh voice unmodulated to meet the ear of the sick person, or well-intentioned willingness linked with lack of foresight, and consequently doing fifty things far better left undone, and keeping the sick-room in a perpetual turmoil instead of that orderly quiet which is so sedative and conducive to repose.

It is impossible not to feel that the successful issue of this remarkable case is due to the aggregation of all these factors: (1) an admirable patient; (2) circumspect, intelligent medical attendants; and (3) rational, well-behaved, self-controlled relatives, who, whatever they might feel, maintained a perfect composure of manner. Under such an aggregation even a wounded peritoneum has conducted itself admirably, and demonstrated how in recent times this large serous sheet can tolerate injuries to it without actively resenting them. Certainly the case in all its details is one of great scientific interest, carrying with it a message to all time. What amount of the success so far attained is due to the adoption of Lister's principles of local treatment, it is difficult to say; but it clearly seems entitled to some portion of the credit. The antiseptic seems to render innocuous the decomposing particles of the tissues actually killed by the impact of the bullet, which otherwise is such a grave source of danger. Where the bullet is actually lodged is only a matter for speculation; but, wherever it is, it seems to be exercising no injurious influence. Indeed, if it be unaccompanied by any particle of clothing, as seems the case, the leaden missile may become encysted by a capsule of connective tissue, and may be thus rendered inert and devoid of harmfulness, never making its presence felt during the rest of President Garfield's existence, which we all trust will be a prolonged one. The good feeling displayed by the sympathy with the wounded man and his family, evidenced on all sides and among all ranks of life here, will do much to cement the union betwixt two large peoples speaking the same language, as its wide issue; the success of the case will, as a minor issue, demonstrate the claims of American surgery to the respect of all. Because we in Europe see the American visiting us in his brief holiday, working hard, seeing everything, evidencing an ardent thirst after information, carrying away with him everything it is possible to secure, it will not do to imagine that he has nothing to tell us in return if he chooses to assume the rôle of teacher rather than that of student. Otis and Sayre have recently put the Britisher up to a thing or two; albeit their lessons have only been very imperfectly imbibed in a considerable proportion of cases. When the representatives of medicine and surgery assemble next month, there is every reason to hold that the delegates from the United States of America will have no cause to hide their heads at the position they will take in the mighty Congress. Of course there are probably many men on the Continent, as there undoubtedly are here, who are unfamiliar with the work done in the New World, who will be surprised at anything advanced in the United States of America, except the construction of revolvers and amusing newspaper paragraphs, or gigantic schemes for the transference of money from one pocket to another, and to whom Barnum, Colt, and Jay Gould or Jim Fiske are the best-known names. But instead of such ignorance being a matter to be proud of, as was not so very long ago the case, the better informed now show in their familiarity with matters American a spirit of appreciation which will develop further with time.

J. Milner Fothergill.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting of the Society was held at the Hall of the College of Physicians, Philadelphia, May 25, 1881, Dr. Albert H. Smith, President of the Society, in the chair. Dr. Wm. M. Welch read a paper on "Vaccination" (see page 705), which received a vote of thanks and led to general discussion.

DISCUSSION.

Dr. Henry H. Smith said that physicians generally should pay more attention to the method of vaccinating and to the course of the vesicle, in order to see whether it passes regularly through its different stages of devel-

opment in a typical manner. In order that vaccination may be effective, the virus should be introduced under the skin in a state of solution.

Dr. Ludlow agreed with the last speaker, and insisted upon the umbilicated character of the vesicle as a diagnostic point. He believed that many persons presumed that they had been vaccinated when the procedure had not been properly performed and was not protective, and referred to the fact that some have to be vaccinated a number of times before it would "take." Occasionally the papule is delayed for several days — even ten days—before it shows itself after vaccination.

Dr. Wm. P. Moon referred to a limited outbreak of smallpox in a public hospital, and the measures taken to control its spread. On the 9th of December, 1880, a patient, and on the succeeding day a servant, in the female department of the Pennsylvania Hospital for the Insane were discovered to have a severe attack of variola. Both were sent to the Municipal Hospital. On the 17th of December, 1880, a case of varioloid occurred in the person of the steward's wife. From that date to the 6th of January there had occurred thirteen cases. The hospital consisted of a central building with north-and-south wings, the latter of which was carefully isolated, and the cases were in this way confined exclusively to the south side of the house. Vaccination and revaccination were practised. Only seven or eight cases had not been previously vaccinated. Three hundred and sixty-two in all were vaccinated, one hundred and fifty-two on the south side and one hundred and ten on the north side. In the series of one hundred and fifty-two revaccinations, ninety-four took. Of these, eighty-four were vaccinated for the second time, twenty-six the third time, six the fourth time, three the fifth, and one the sixth. Out of the one hundred and ten on the north side, ninety-five were revaccination cases, nine second, two third, leaving only four which did not take of this series,—so reported by Second Assistant-Physician Henry B. Nunemaker, M.D.

The appearance of smallpox in a hospital situated as this one is caused much anxiety for its results; but, owing to the care in isolating patients, the endemic was confined to one side of the house. There was ample room for treating the cases. The centre buildings were vacated, and communication shut off from the two sides. Two cases occurred in the centre building, but no others after these had been removed to the south side.

Dr. Wm. T. Taylor said that he did not hesitate to vaccinate women during pregnancy, and reported a case where it seemed also to protect the infant. A young lady was taken with varioloid; in the same house there was a woman six months pregnant, who was at once vaccinated and escaped the disease. At the end of utero-gestation a brother of the lady was lying in an adjoining room sick with smallpox. The speaker vaccinated the infant again and again, but it would not develop. Nor did it take the smallpox. The question is, was the child protected by the vaccination of the mother during pregnancy? As regards the mode of vaccination, for the last fifteen or twenty years he had vaccinated with the needle (tattooing), using humanized virus, except occasionally when he used an ivory point. Softening the lymph-crust to the consistency of cream, it is put on the arm reddened by previous scraping, and with the needle it is pricked in fifteen or twenty times. This generally succeeds. For many years he used the crusts occasionally, keeping them for months. Lately he has commenced the use of animal virus. He also mentioned a case which had been vaccinated a number of times without any effect, as an instance of natural immunity from vaccinia.

Dr. Benjamin Lee said that in a paper previously read before this Society, in 1872, one of his conclusions was that bovine lymph was not quite so lively, the human system was not quite so susceptible to its influence as to humanized virus; but his experiments had been made with bovine virus imported from Germany in hermetically-sealed tubes, which, perhaps, had lost some of its properties. The providing of lymph should not be left to private enterprise and speculation, but every large centre of population should have a vaccine farm, and no virus should be sent out without official approval. It is not likely that we shall ever return to humanized virus. It is therefore of great importance that bovine virus should come clothed with some authority.

The lecturer had said that a vaccination might be protective and yet not pursue a typical course. He inquired what would be the test by which this might be known.

Dr. Jas. K. Collins said that twenty-five days before he had vaccinated a baby three weeks old with a bovine point obtained from an apothecary. On the fourth day the spot was red; on the tenth day a crust had formed, which fell off on the twenty-first day. Shortly afterwards he was called to see another member of the family: the child was perfectly well. On the same evening she was seized with opisthotonus; occasionally her jaws were tightly shut. She died at five o'clock the following morning with tetanus. It is the first case of the kind that he had ever met with. There appeared to be no other evidence of injury than the vaccination. The case seems unique, as he had not been able to find a parallel case.

Dr. W. R. D. Blackwood insisted upon the proper performance of vaccination, and endorsed the methods proposed, preferring in his own practice scarification,—dipping the point in water, shaking off the surplus water,

then rubbing the virus on the scarified portion for a minute or two. He reported a case in which a pregnant woman (eight months) was protected by vaccination, although small pox was in the same house. The infant never was vaccinated, but has since passed through an epidemic safely. He was therefore satisfied both that vaccination was protective after exposure and that vaccination in the later period of gestation also protects the child. He has not now used humanized virus for many years, except by special request. In using a crust he invariably pulverizes it in a mortar, and sees that it is perfectly dissolved before using it. He believed that he had seen two undoubted cases of syphilitic infection by vaccination.

Will vaccination take on those who have had smallpox? In a case of a girl eight years old, with well-marked pits upon her face, he successfully vaccinated, leaving two well-marked scars upon the arm. In a public institution he had vaccinated two hundred and thirty-four cases of all ages up to sixty and one hundred. Some of the revaccinations had typical scars just as much so as in the infants.

Dr. M. O'Hara thought that the exact value of vaccination as a protective against the smallpox cannot be estimated. He had seen people die in a second attack of smallpox. A physician died at the hospital in the third attack. We should not, therefore, ask too much from vaccination. Some persons are insusceptible to both vaccination and smallpox. Another element of doubt is the epidemic constitution of the air, which greatly affects the spread of the disease and its malignancy. He believed that much work was yet to be done in compiling the statistics of the Board of Health, in order to find out how many deaths have been prevented by public vaccination. A great amount of work had been done, and he would like to have this evident in the diminution of the death-rate.

Dr. S. K. Baldwin corroborated the remark made by a previous speaker in regard to obtaining typical vesicles in old people, even in revaccinations.

Dr. Wm. S. Stewart said that he had reported a case of supposed smallpox to the Health Office, but was told that she could not be taken to the hospital until the eruption showed itself sufficiently to enable him to be positive. He believed that the patients would do better if they could be moved earlier. He endorsed all that had been said in the paper. He had seen a case where a mother had an attack of confluent smallpox. The child was vaccinated, and, although nursed by the mother, did not have the smallpox.

Dr. Albert H. Smith had been educated in the school that believed that vaccination of pregnant women was little less than homicide. Having seen a case of varioloid terminating fatally after miscarriage at about six and one-half months, he made up his mind to vaccinate every pregnant woman where exposure had occurred, and he had since done so up to the present date. He had seen no more fatal cases since he had adopted this plan, which he highly recommended, as the danger is so much greater from variola in this condition that we are warranted in running the risk of the vaccination. His experience had been considerable, and he had never seen the slightest evidence of any disturbance of the ovum, nor threatening of miscarriage. This is a subject of vital importance, because the pregnant woman will probably die with variola if unprotected.

His experience in regard to children was different from a former speaker's. He had never failed in primary vaccination in young children. He has used bovine virus invariably for a number of years.

Dr. Arthur Meigs said that the lecturer had not stated how many insertions he was in the practice of making in vaccination, and, in the second place, in the revaccinations he had not said whether it was performed only once or more than once; in the third place, he would inquire whether a person insusceptible to vaccination could be regarded as safe from an attack of smallpox.

Dr. W. H. Parish endorsed the statements in regard to the comparative safety of vaccination of pregnant women. He had in no case seen any inconvenience resulting.

Dr. Frank Woodbury said that as a test of successful vaccination the method of double insertion had been recommended,—that is to say, the virus is inserted twice, with an interval of a day or two between. In a successful vaccination the second vesicle will catch up and develop simultaneously with the first. He thought that this simple method might be more frequently practised. In regard to the work of the public vaccine physicians, he believed that, instead of the supply of lymph being left to individual enterprise, the city authorities should take especial pains to supply the vaccinators with genuine bovine virus. Perhaps part of the failure which has been claimed to exist is due to want of proper care in the selection and use of the material they employ in vaccinating. He also referred to the present epidemic of smallpox and to the unsystematic and inefficient means adopted by the Board of Health to prevent the spread of the disease, and also to the inadequate accommodations for conveying patients to the hospital. Practically, no restrictions have been placed upon those cases of smallpox which are reported by their attending physicians as being cared for at home, nor upon their attendants. Visitors to the smallpox hospital also come and go in the regular street-cars without hindrance. Very imperfect, dilatory, and unsatisfactory measures have been taken for the disinfection of wearing-apparel and bedding, or infected prem-

ises. The manner of conducting patients to the hospital is lacking in humanity, often injurious to the patients, and extremely discreditable to a great city like Philadelphia. Cases were mentioned where patients, instead of being carried directly to the hospital, were carried in the ambulance for several miles out of their road in order to pick up other patients, to their great injury, and increasing the risk of infection in case a mistake in diagnosis had been made. Moreover, no physician is sent with the ambulance, and the responsibility of making the diagnosis is thrown upon the ordinary physician who may happen to be called in. Thus it happens that patients are not reported for removal until the eruption is fully out, and they are subjected to the risk at a time when their disease is at its height, and when the danger is naturally greatest. A case was also reported in which a respectable woman was attacked by variola, and was ordered to be sent to the hospital by her physician on account of the supposed better accommodations, although she had a comfortable home. When the ambulance arrived, it was found that it already contained a burly negro covered with smallpox eruption,—the most repulsive object that could well be imagined,—and the husband was required to carry his beloved and still conscious wife down-stairs and deposit her by the side of the other patient. Thus was she dragged away. He never saw her again, for she died in the pest-house; but he will never forget her parting look, nor this gross insult put upon him by the carelessness or parsimony of some one in authority. In conclusion, Dr. Woodbury contended that during such an epidemic as we have just passed through, house-to-house visitation by public health officials is imperatively demanded, who should be clothed with authority to isolate the sick, or, what would be better, order all cases at once and without exception to the hospital for treatment; and, further, that enough ambulances should be provided to allow of the carrying of patients singly and directly to the public hospital.

In connection with the last case it was also said that after exposure the whole family and the speaker himself were promptly vaccinated with bovine virus obtained from a regular dealer, which was supposed to be reliable, but was utterly worthless. It not only afforded no protection at all, but gave a false sense of security and prevented genuine vaccination from being practised.

Dr. H. F. Baxter said that much of the bovine virus is bad. He had used it, and he had never seen a typical vesicle. With humanized virus he had vaccinated six or seven thousand cases successfully, and had only been able to trace a single case of varioloid occurring in all these cases.

Dr. W. M. Welch, in closing the debate, spoke of the importance of introducing the lymph in a state of solution, the surface being prepared by slight scarification with a lancet. He believed that since the introduction of bovine virus (1870) there has occurred some change in the course of the vaccine pustule. Some years ago, with long-humanized lymph, the scab would fall off, or could easily be taken off, on the fourteenth or fifteenth day; now the crusts remain often until the fourth week, and sometimes longer. There is therefore some difference in its course, but whether or not there is any variation in the protective power there is room for doubt. In regard to the local effects, he did not think that a great amount of inflammatory action makes the vaccination more protective. Concerning insusceptibility to vaccinia, he believed it to be rare, but spoke of one case where he had failed after several attempts at primary vaccination, and subsequently, during an epidemic of smallpox, he tried it again, and succeeded in vaccinating the child. He had admitted patients vaccinated in infancy into the hospital with smallpox, who had been exposed to the contagion some years before without contracting the disease. If, therefore, it is true that persons may be susceptible to vaccination or smallpox at one time and not at another, is it not wise to vaccinate all persons, whether or not previously vaccinated, during an epidemic prevalence of the disease?

As regards successful revaccination, those subjects who are vaccinated within the first year of life are more apt to be successfully revaccinated at puberty than children vaccinated at a later age. He approved of vaccination, when necessary, during pregnancy, and believed that a child born under such circumstances might possibly be protected against smallpox or vaccination, though, in his opinion, this would not be the rule. Abortion very frequently occurs as the result of smallpox in pregnancy, but not always. He had kept records of some cases that went on to full term afterwards, and the child bore no marks of having undergone smallpox *in utero;* and he had never failed to obtain a characteristic vaccination. But cases have been reported where the child has survived an attack of smallpox *in utero.* Such a child would doubtless be insusceptible to vaccination. A case of miscarriage recently occurred in the hospital, in which the fœtus showed an unmistakable vesicular eruption on all parts of the body. If, therefore, the fœtus may have smallpox, may it not also be protected by vaccination of the mother?

While the bovine virus now obtainable, for some reason or other, much more frequently succeeds in inducing vaccinia than that which was in the market some years ago, it is still to be feared that much of it sold as genuine is spurious and unprotective. Dr. Martin, of Boston, in reply to a letter, wrote to the speaker that there is a great deal of spurious lymph in use, and said that many of the so-

called "cones" are particularly bad, being made up largely of dung, urea, hairs, epithelium, and only about five per cent. of animal lymph. They sometimes succeed, but more often fail, or produce spurious results.

In cases apparently insusceptible to vaccination by ordinary methods, Dr. Welch recommends fresh eight-day humanized lymph or arm-to-arm vaccination. This he has always found to be successful. Very few persons are naturally insusceptible to smallpox. He mentioned a case exposed in the hospital, and without any vaccination scar, who could not be successfully vaccinated, and who did not take smallpox; but such cases are entirely exceptional. As regards the protective power of vaccination, he was fully convinced of it. Families are often sent to the hospital, some of the members having smallpox and others well and unvaccinated: the latter, being vaccinated after admission, not unfrequently are protected against smallpox, although daily exposed to it. But, unless the vaccination gets a certain start of the disease, it exerts no modifying effect upon it whatever. Two families now at the hospital illustrate the protective power to a high degree. In one containing eight persons, all were sick except the mother, who previously had had varioloid, and a child with a well-marked cicatrix from vaccination. This one child, vaccinated two years before, was the only one of the family exempt from smallpox,—none of the other children having been vaccinated. In another family, two vaccinated children lived among the smallpox cases without taking the disease, while all the rest of the family, not being vaccinated, were sick with it.

As regards the number of insertions, he had statistics upon this subject, which had appeared in the reports of the Board of Health. During the epidemic of 1871–72—when a large number of cases came under his observation—he found that one good cicatrix gave quite as much protection as half a dozen. He had seen persons with ten or twelve—even as many as seventeen—typical scars from vaccination in infancy suffer from smallpox, and he has known deaths to occur among such. Of course they had not been revaccinated.

In regard to Bryce's test mentioned by Dr. Woodbury, of vaccinating twice, with several days' interval,—the crusts dropping off at the same time,—he did not consider it of great value where the vaccination performed first was genuine.

COPAIVA IN SCIATICA.—

℞ Bals. copaivæ, ʒiv;

S.—A tablespoonful every four hours.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, MAY 26, 1881.

The PRESIDENT, DR. S. W. GROSS, in the chair.

Primary cancer of the gall-bladder. By Dr. J. H. MUSSER.

MRS. McM., the patient from whom the specimens before you were removed, was under my care from the 9th of March until the 4th of May, 1881. Her illness dated from the middle of December, 1880, and continued until the 18th of May, 1881. She died in the Presbyterian Hospital, and I am indebted to Dr. Markoe for the privilege of this exhibition. The history previous to my attendance was apparently that of an intermittent fever with hepatic and gastric complications. The symptoms referable to the liver were paroxysmal lancinating pains in that region, at times so severe as to almost cause collapse. The gastric symptoms were epigastric pain, loss of appetite, flatulence, acid eructations, and, at variable intervals, attacks of vomiting. She had not been jaundiced.

I found her suffering from an intermitting fever with daily paroxysms, each beginning about 1 P.M. and continuing until 7 or 8 P.M. The chill lasted a half-hour, and was moderately severe; the fever lasted four hours, at its height the temperature being 103°. She was emaciated; her features indicated exhaustion and were somewhat pinched; her complexion was sallow; she was anæmic.

She suffered from severe paroxysmal pains in the epigastric and hypochondriac regions. The areas were tender on pressure, but no tumor was noticed. The liver-dulness extended three inches below the ribs in the nipple-line. The spleen was twice its natural size. The appetite was lost. She had nausea, acidity, and flatulence. The bowels were constipated. Urine contained neither albumen nor sugar. Urates and uric acid were in abundance.

During the course of her illness the symptoms may be detailed under three headings,—febrile, gastric, and hepatic. There seemed to be no relation between the different sets of symptoms, except the febrile and hepatic. The fever was more continuous when the jaundice was deepest. At the risk of some repetition, I will note them.

Gastric.—Tongue covered with a dark-yellow, heavy fur, moist, tremulous; later dry and brown. Bitter taste in the mouth, secretions viscid, loss of appetite, thirst, acidity, flatulence, weight and fulness after meals, epigastric pain and tenderness, nausea and vomiting. I desire to call particular attention to the nausea and vomiting. It, of all the gastric symptoms, was especially independent of any other symptoms. It occurred once in two weeks, once a week, or twice a week.

Each paroxysm lasted from two to four days. The fluid vomited varied, from a clear-white, sour, to a greenish-yellow, bitter liquid.

Hepatic.—Pain in the right hypochondriac region, paroxysmal, sharp, and lancinating, radiating to right and left shoulders and to epigastrium; tenderness on deep palpation, absence of tumor or irregularity of edges, enlargement as noted above. On account of liver-derangement, marked jaundice, with clay-colored stools and bile in the urine. The jaundice occurred four times while the patient was under my care. The first attack was light, lasting three days; the second and third each lasted a week; the fourth, beginning on the 25th of April, continued till death. With the second and third attacks the fever was remittent in character; with the last it was continuous. As the jaundice improved, the fever changed from the remittent to the intermittent type.

Febrile.—As may be inferred from the previous notes, the fever was irregular. At first it was intermitting, then remitting, and finally it became continued. At no time was the temperature higher than 104°. With the rise in temperature there was a corresponding pulse-rise. The increased pulse was not as great as a pulse at the height of a paroxysm of intermittent by twenty beats. The last month of illness it became rapid, feeble, compressible, and dicrotic. When the fever was remittent or continuous, in the evening there was delirium. The "typhoid" state developed the last ten days of her life, and death took place from cardiac failure. The use of antiperiodics prevented the paroxysms at first. As soon as the drug was suspended they recurred. Finally, in spite of any remedies, the fever continued.

The following facts also bear upon the case. The patient was a married woman, who had not lived with her husband for several years, on account of his brutality. She was 37 years old, a nurse by occupation. She had always been in poor health, and had had several attacks of biliary colic. The family history was good, save that a maternal aunt died of cancer. Her mother and brothers were living; her father had been killed.

The post-examination was made by Dr. Warnock. He reported that rigor mortis had set in early, that the body was greatly emaciated, and that all the tissues were stained with bile. With the exception of the liver and spleen, the organs were normal for a person who had died of heart-failure. The liver and spleen I examined carefully. The latter organ was about twice the normal size, of a dark greenish-brown color, of about normal consistence. Unfortunately, it was not examined microscopically.

The liver was of a peculiar shape. The right lobe was eight inches long, the left the same. Curiously, however, the lower edge of the latter lobe did not extend as low down as that of the right lobe, but its upper edge was three and one-half inches beyond the same edge of the right lobe, while the lobe was doubled on itself to conform with the concavity of the diaphragm. Transversely the right lobe measured five and one-quarter inches, the left three and one-half. The former was two and one-half inches thick, the latter one and one-half. The gall-bladder was in the normal position and of the normal size. It was adherent to the duodenum. The color of the outer portion was pure white, not bile-stained. It was not collapsed, and was of firm consistence. A portion of the bladder underneath the liver, not quite as large as a walnut, was of natural color and fluctuated.

On section of the gall-bladder it was found that the white appearance of the exterior was due to cancer, which involved three-quarters of the organ. The growth encroached upon the cavity so that the walls were from one-half inch to one inch thick. The mass was of the appearance of a soft cancer; the inner surface had a ragged, ulcerated appearance, and in the centre of the mass was found a gall-stone the size of a filbert, with a rough surface, looking like a mulberry calculus. The stone was lying against the mouth of the gall-bladder; behind the stone was a cavity about the size of the stone, filled with a thick greenish-yellow fluid. From the appearances one would infer that the stone acted as a ball-valve to the duct. The duct was involved to and beyond the junction with the hepatic duct. The hepatic duct was enlarged, its walls thickened, its calibre much increased. The branches extending into the upper half of the right lobe were greatly dilated, even almost to the periphery of the liver, terminating in saccular dilatations. The ducts contained a thick grayish-green matter; the walls were of a slate-gray color, dotted with dark points. The liver-substance traversed by these ducts was dark and soft, not unlike gangrene. A part in the centre about three inches square was especially of this appearance. The remainder of the structure of the organ was slightly stained with bile and fatty in appearance.

On microscopic examination the malignant mass was found to be of the nature of a medullary cancer. The cystic and part of the hepatic duct was involved. The transition from the cancerous to the catarrhal process in the ducts was well marked. In the liver, catarrhal inflammation of the ducts was very distinct. In the lymphatic spaces around the ducts there was an abundant infiltration of epithelioid or indifferent cells. It was impossible to say, though it was highly probable, that the disease had involved the ducts. No doubt such would have been the case had the patient lived longer. The cancer of the gall-bladder was no doubt primary, from the ragged appearance of the mass and the absence of nodules. I shall try to determine

why the special ducts were involved, and will report the result to the Society. Dr. Formad very kindly confirmed the examination.

I desire to discuss elsewhere, in detail, the etiology, the clinical history, and the diagnosis. Remark, however, the relation of the gall-stone to the new growth as cause and effect in a person predisposed to cancer. Let me say, too, that I did not diagnose cancer of the gall-bladder. Long before her death I suspected internal malignant disease.

Dr. FORMAD said that he had examined the specimens microscopically, and had readily detected the presence of carcinoma of the soft type. The gall-ducts were strongly catarrhal, and the surrounding lymphatics were crowded with a small-celled infiltrate, which might possibly be metastatic, as some of the cells had a suggestive look. The presence of gall-stones in this case was of interest, as pointing to a local origin of the disease, since primary carcinoma of the gall-bladder is excessively rare.

Dr. MUSSER replied that Murchison teaches that primary cancer of this organ is always associated—probably causatively—with the presence of gall-stones.

THURSDAY EVENING, JUNE 22, 1881.

The VICE-PRESIDENT, DR. JAS. TYSON, in the chair.

Specimens removed in a case of preventive trephining for a compound comminuted depressed fracture of the cranial vault. Presented by Dr. C. B. NANCREDE.

Hugh McD., æt. circa 25 years, was admitted to the male surgical wards of the Protestant Episcopal Hospital in August, 1880. When I saw him his mind seemed clear, but his pulse was decidedly slow for a man who had been so severely injured and who had lost considerable blood. He had been struck down into the hold of a vessel by the falling upon him of about a ton of iron ore, which crushed his left leg to such an extent as to demand amputation. The fracture of the skull-vault must have been produced by his head striking against the corner of a bolt-head or nut, as it had evidently resulted from contact with some small, comparatively pointed object. The bone was much depressed over a small area, somewhat resembling a punctured fracture. Considering that, from its appearance, the inner table was probably extensively fractured, and believing as I do in "preventive trephining," I removed a circle of bone, elevated the depressed portions, and removed a number of fragments of the inner table, which had been driven down upon the brain and forced beneath the contiguous undepressed portion of bone. The wound was dressed antiseptically. As far as the head-trouble went, he did uninterruptedly well. If more compound comminuted depressed fractures of the skull were elevated before secondary mischief was lighted up, many more cases would recover than do under the present "let-alone" plan of treatment. I merely present this case as a typical one, for this is the second within a year in which I have performed preventive trephining successfully. After inflammatory trouble has been set up, trephining does not usually effect more than a temporary relief of the symptoms.

Dr. HENRY asked whether any symptoms of motor paralysis had been noted, as such cases would tend to prove the correctness of Ferrier's views. The site of this injury was such as should have produced motor paralysis of the upper extremity.

Dr. NANCREDE said that none had been detected.

Dr. SEILER related a case which he had seen when last in Vienna, where, by the knowledge gained by the experiments as to cerebral localization, the surgeon had correctly diagnosed the site of an old depressed fracture, which he had successfully removed by the trephine.

Dr. HENRY mentioned Dr. Detmold's successful case of trephining and opening of an abscess deeply seated in the brain-substance.

Dr. NANCREDE then made some remarks upon what had been done in the direction of a practical application to surgery of cerebral localization in France, and cursorily reviewed some of the recent literature of the subject.

Tumor of shoulder. Presented by Dr. J. M. BARTON, for Dr. L. H. ADLER.

The growth which I here present for Dr. L. H. Adler, of this city, was removed by him on the 24th instant from the shoulder of a married lady 28 years of age. It was covered only by skin and superficial fascia, but the deeper portions were embedded in the trapezius muscle. It had a distinct capsule which was closely adherent to the muscle, and had to be removed by a tedious dissection. It had no bony attachments. The growth was noticed for the first time about two years ago, the patient stating that it was nearly as large then as now. It has never been the seat of pain, and the general health of the patient has been unaffected. The skin over the tumor was perfectly healthy. It was situated on the anterior edge of the trapezius muscle opposite the middle of the clavicle.

COCA WINE.—Under the name of *vinum Mariani*, says the *British Medical Journal*, Messrs. Roberts & Co. are introducing into England a preparation of coca prepared from the leaves of the *Erythroxylon coca*. It forms a very agreeable and, according to the clinical experiences of physicians in France as well as England, a very useful nervine stimulant. It is valuable as a remedial agent in cases of nervous exhaustion, over-study, or excessive mental exertion.

REVIEWS AND BOOK NOTICES.

SUPPLEMENT TO ZIEMSSEN'S CYCLOPÆDIA OF THE PRACTICE OF MEDICINE. Edited by GEORGE L. PEABODY, M.D. New York, William Wood & Co., 1881. 8vo, pp. 844.

This work is intended to cover only the ground gone over in the original Cyclopædia, and it aims to make such additions as recent investigations and publications have rendered necessary.

The advantage of such a book as the present is that it gives the result of recent advances in medical science in a convenient shape for the busy but studious practitioner. The names of Dr. Peabody's collaborators are a sufficient guarantee that the work has been well done. Typhoid, Relapsing Fever, and Plague are dealt with by Dr. G. B. Shattuck, of Boston; Yellow Fever, by Dr. G. M. Sternberg, U.S.A.; Croup and Diphtheria, by Dr. F. P. Kinnicutt, of New York; Varicella, Measles, Rickets, by Dr. F. Forcheimer, of Cincinnati; Smallpox, by Dr. F. P. Foster, of New York; Malarial Diseases, Dengue, by Dr. Henry M. Lyman, of Chicago; Cerebro-Spinal Meningitis, by Dr. J. Lewis Smith, of New York; Syphilis, by Dr. Jas. Nevins Hyde, of Chicago; Glanders and Anthrax, by Dr. James Law, of Ithaca; Hydrophobia, Trichinosis, Intestinal Parasites, by Dr. T. E. Satterthwaite, of New York; General Diagnosis and Therapeutics of the Diseases of the Larynx, by Dr. George M. Lefferts, of New York; Diseases of the Nose and of the Pharynx, by Dr. J. Solis Cohen, of Philadelphia; Diseases of the Pleura, by Dr. G. M. Garland, of Boston; Diseases of the Lungs, by Dr. Shattuck; Diseases of the Heart and Pericardium, by Dr. T. M. Rotch, of Boston; Diseases of the Arteries, Veins, and Lymphatics, by Dr. A. T. Cabot, of Boston; Diseases of the Stomach, Intestines, Spleen, by Dr. E. G. Cutler, of Boston; Diseases of the Bladder, Urethra, Prostate, etc., by Dr. R. F. Weir, of New York; Diseases of the Liver, by Dr. R. H. Fitz, of Boston; Diseases of the Female Sexual Organs, by Dr. Foster; Diseases of the Peripheral Cerebro-Spinal Nerves, by Dr. S. G. Webber, of Boston; Diseases of the Brain, etc., by Dr. L. Putzel, of New York; Diseases of the Spinal Cord, by Dr. R. Van Santvoord, of New York; Vaso-Motor and Trophic Neuroses, by Dr. J. J. Putnam, of Boston; Diseases of the Kidney, by Dr. A. B. Ball, of New York; Rheumatism, etc., Osteo-Malacia, Anæmia, Scrofulosis, etc., by Dr. C. E. Hackley, of New York; Diabetes, by Dr. H. N. Heineman, of New York; Hæmophilia, Purpura, Scurvy, by Dr. H. M. Bannister, of Chicago; Toxicology, by Dr. E. S. Wood, of Boston. We have given a list of authors and subjects at length because we think that in no way can we better convey an idea of the scope of this valuable work. When we add that the articles are for the most part accompanied by a bibliography (that on syphilis being, very unfortunately, an exception), the reader can see that the book is one to be kept in mind for reference, and one which, if possible, should be placed upon the library shelves.

THE ORTHOPRAGMS OF THE SPINE. An Essay on the Curative Mechanisms applicable to Spinal Curvature, exemplified by a Typical Collection lately presented to the Parke's Museum of Hygiene, University College, London. By ROBERT HEATHER BIGG, Assoc. Inst. C. E. London, T. & A. Churchill, 1880. 8vo, pp. 150.

What is an orthopragm? That is the first question which will occur to the average reader on picking up Mr. Bigg's book, and for its solution we must refer him to the work in question itself. Mr. Bigg studies the human spine from the mechanical point of view, first in its normal conformation, then in its abnormal variations, and finally the broad principles upon which *restitutio ad integrum* is to be brought about by mechanical means.

ATLAS OF SKIN DISEASES. By LOUIS A. DUHRING, M.D., Professor of Skin Diseases in the Hospital of the University of Pennsylvania, etc. Part IX. (concluding the series). Philadelphia, J. B. Lippincott & Co., 1881.

We congratulate Professor Duhring on the accomplishment of his arduous labor in connection with this truly monumental production. Unaided and alone he has pushed through to completion, amid obstacles which those only can appreciate who have attempted a similar enterprise, a work which will last when systems and treatises are obsolete and forgotten; for the faithful delineations of disease, whether by pencil or by pen, can never become obsolete. We have frequently taken occasion, in our notices of the various parts of Professor Duhring's Atlas, to express our pleasure and admiration at the truthfulness and character of these representations of average skin diseases as found from day to day. Resisting the temptation to depict strange and monstrous diseases *ad captandum vulgus*, he has been content to represent skin diseases as the practitioner finds them; and in this lies the high value of his Atlas.

The present and concluding fasciculus comprises two plates of *eczema rubrum*, one of *pemphigus*, and one of *ecthyma*, of which we need say no more than that they are fully up to the standard of the previous plates,—the ecthyma, in fact, being, in our opinion, one of the most perfect in the series. A table of contents and a classified arrangement of the plates are placed at the end of the fasciculus, and the parts may be arranged for binding either as they have been issued or with the various affections grouped in due nosological order. Seven of the nine classes of skin diseases are represented in the completed

Atlas, the hyperæmias and the neuroses alone being unrepresented. Eczema, as the commonest of skin diseases, comes in for eight plates, representing it in all its various forms. Syphilis is represented by six plates, and the other affections by two or one each. Thus the whole ground is gone over, and the practitioner who has Duhring's Atlas is prepared for most of the affections with which he is likely to meet. The letter-press should not be ignored. It is not merely a description of the plates, but a condensed and carefully-written account of the disease, with the more trustworthy forms of treatment ordinarily employed. A. V. H.

GLEANINGS FROM EXCHANGES.

ORTHOPNŒA.—Dr. Henry Cook (*Practitioner*, June, 1881) defines the term orthopnœa to mean that exaggerated condition of dyspnœa in which the act of lying down becomes impossible, and the patient is constrained to assume the upright posture more or less absolutely, owing to the sensation of want of breath which supervenes on attempting to assume the prone position. A patient suffers from orthopnœa when,—1, he cannot fully inflate his lungs, either because of fluid or air in the pleural cavity, fluid in the air-cells and smaller tubes, consolidation of the lung, pneumonic or phthisical (though the condition in these is rarely met with), asthma, stenosis of the glottis from œdema or otherwise, emphysema, abnormal fulness of the abdomen (preventing the descent of the diaphragm), ascites, tympanites, and enlarged liver and spleen. 2. A patient suffers from orthopnœa when the circulation fails through inefficient action of the heart, from thinned or degenerated walls, from inefficient valves, from stenosis of its orifices or from fluid in the pericardium, from aneurism, or from tumors of the thoracic cavity.

In all these cases the essential condition giving rise to the orthopnœa is failure of or imperfection in the oxygenation of the blood, and consequently the circulation of impure blood through the nervous system. This, so long as the nervous system is still sensible of the injury done to it, incites the patient to make efforts to relieve the circulation of blood through the lungs. When the nervous system becomes oblivious to this circulation of impure blood, the patient gives up the struggle and assumes the recumbent position,—a sign of the worst import, and, indeed, of impending dissolution.

Dr. Cook gives several cases illustrative of the various forms of orthopnœa, and then goes on to inquire, "Why is the sitting posture essential to the successful performance of respiration in these cases?"

In cases of ascites the erect posture acts mechanically in relieving the diaphragm; the same is true to a less degree in general dropsy, the interference being purely mechanical. But in diseases of the heart and aorta we must look deeper for the causation. Dr. Cook does not believe that the prone position can, under any circumstances, interfere with the action of the heart itself, nor does he think that the blood-flow in conditions resulting from imperfect valves could be influenced by this position. Whether, however, the nervous energy of the heart and arterial system can be affected by position is open to critical consideration. The conditions affecting this are very complicated and intricate, and include the nervous supply to the heart, both cerebral and sympathetic, and the vaso-motor supply to the arteries.

Dr. Cook thinks that as the great sympathetic ganglia which supply the motor force to the heart are intimately connected with and acted upon by the other divisions of the double nervous system, it is not improbable that to this central cause may be due the partial paresis of the muscular tone of the arterial system which, he goes on to show, results on assuming the prone posture, and as a result, in part at least, of this, the embarrassed condition of the circulation, and consequently of the respiration, which produces the state of orthopnœa. Experiments with the sphygmograph, tracings from which are included in Dr. Cook's paper, confirm this view.

The treatment recommended by Dr. Cook in cases of mechanical difficulty is that of free purgation by hydragogue cathartics. As regards the physiological difficulty,—this having been shown to be dependent upon diminished tone of the arterial system,—our remedies should be such as are calculated to influence this condition. If we can by the action of drugs restore to a certain extent the lost tone, we may expect to relieve the difficulty of the circulatory system, and, through it, of the respiratory.

Now, digitalis does this. It strengthens the action of the heart, slowing and steadying it, and rendering the contraction of the ventricles more efficient; but, beyond and probably independent of this, it raises the tone of the arteries, increasing the contractile power of the muscular coats and bringing it back to the condition more nearly approaching that of health.

Strychnia may be looked upon as a valuable ally and supporter of the action of digitalis. In Dr. Cook's cases, the hourly administration of nux vomica and digitalis had the best effect.

A NEW METHOD OF TREATING RECTAL FISTULÆ.—Dr. H. A. Reeves, in a note to the *British Medical Journal* (vol. i., 1881, p. 917), says that he operated on a fistula about two and a half inches long, dividing it in the usual way and then scraping away all pseudomembranous tissue and granulations with a sharp scoop. Both surfaces of the wound having

been vivified, and hemorrhage having ceased, three deep silver sutures were passed, entering the skin about a quarter of an inch from the edge of the wound, and, passing well beneath the floor of the fistula, were brought out at the same distance on the other side of the wound. The upper stitch ran through the coats of the rectum into the surrounding tissue. These stitches were removed a week after the operation (but might have been removed sooner), when the wound was soundly healed. The patient has been perfectly well since. Dr. Reeves thinks this plan will do away with the painful dressings which have to be resorted to in the common mode of dressing these wounds, and will expedite the cure of rectal fistulæ. All loose folds of skin about the fistulous track must be removed.

THE EFFECTS OF DRUGS DURING LACTATION ON THE NURSLING.—The result of Mr. T. M. Dolan's experimental inquiry into human milk and the effects of drugs during lactation on either nurse or nursling, as published in the *Practitioner*, may thus be summarized. All therapeutical agents intended to act on the mammary gland must first enter the blood, or be capable of stimulating the blood-supply in the mammary apparatus. This principle follows from what we know of the processes involved in the making of milk, and depends on the general principle that nutrition is dependent on the blood-supply. Further, all drugs derived from the families Dilleniaceæ, Cruciferæ, Solanaceæ, Umbelliferæ, etc., enter the blood and impregnate the milk, so that poisons in any of these classes must be administered with caution to the mother or nurse, lest the nursling be injured. Mr. Dolan has furnished instances where dill, aniseed, and conium had this effect. Again, there is no galactagogue in the sense in which it is understood. The nearest approach to such an agent is to be found in jaborandi; but this drug is not persistent in its action, as it only temporarily affects the mammary secretions. There is, however, an anti-galactagogue,—belladonna. The milk also of the mother may be improved in heat-forming elements by the administration of fat, and the salts of milk may be improved by the administration of medicines. Then various physiological actions—purgative, alterative, diuretic, etc.—may be produced in the child by the administration of drugs to the mother, as is well known. Finally, if we are to expect any improvement in milk-secreting power, as to both quantity and quality, we must look to diet for the attainment of that object.

Three nitrogenized compounds, vegetable fibrin, albumen, and casein, supply flesh-forming food. The chemical analysis of these three substances has led to the very interesting result that they contain the same organic matter, united in the same proportion by weight, and, what is still more remarkable, that they are identical in composition with the chief constituents of blood, animal fibrin and albumen. They all three dissolve in concentrated muriatic acid with the same deep purple color, and even in the physical elements animal fibrin and albumen are in no respect different from vegetable fibrin and albumen. In regard to the presence and relative amount of sulphur, phosphorus, and phosphate of lime, no difference can be observed.—*New York Medical Record.*

HYDROCHLORIC-ACID POISONING — RECOVERY.—Dr. MacDonald (*Edinburgh Medical Journal*, June, 1881, p. 1093) was called to see a man who had taken an ounce and a half of hydrochloric acid, presumably in one gulp, as there was no corrosion of the mucous membrane of the mouth or fauces. He had taken, by way of antidote, before the doctor's arrival, a teaspoonful and a half of bicarbonate of sodium, and a bottle of soda-water. Dr. MacDonald immediately gave him a cupful of solution of carbonate of sodium, which was rejected with some coffee-ground-like matter. The patient was then surrounded with hot-water bottles, and was directed to have milk alone as a nourishment. Subsequently the temperature rose to 102°; pulse, 100 to 108. The epithelium of the tongue became leathery and ichthyosed in appearance; and this cleared off on the tenth day. There was complaint of pain opposite the cardiac and pyloric stomachic orifices, and general tenderness over the abdomen. Opium was given for sleeplessness, and turpentine stupes were placed over the whole abdomen. A little diarrhœa of irritation set in, the stools smelling of turpentine. The inflammatory danger over, convalescence was uninterrupted save by a little cough, which succumbed to an ordinary mixture. Dr. MacDonald remarks on this case that it gives evidence of the low corrosive power of hydrochloric acid; the absence of mouth-signs to aid the diagnosis, which might happen in a case where no information could be had as to the poison taken; the diarrhœa of irritation containing absorbed turpentine; and the apparent general result to the patient of only some gastric catarrh, evidence of œsophageal stricture or gastric ulcer being in the mean time wanting.

CARBOLIC ACID IN WHOOPING-COUGH.—Dr. MacDonald (*Edinburgh Medical Journal*, 1881, p. 1094) says that on extended trial he finds carbolic acid, in doses of one-fourth minim to a child of six months, one-half minim for a year, and one minim for two years and upwards, to be the best remedy for whooping-cough. The whoop goes; the vomiting ceases; the paroxysms are modified in intensity and frequency. This result Dr. MacDonald believes to arise from a similar action to that of creasote on the motor fibres of the vagus to the stomach, and from a lowering of vitality of the specific germ of whooping-cough disease. This points to the

antiseptic treatment of the zymotic diseases generally.

BELLADONNA-POISONING TREATED SUCCESSFULLY BY PHYSOSTIGMA.—Dr. Hudson, of New Zealand (*British Medical Journal*, vol. i., 1881, p. 918), in the case of a man who had injected a considerable amount (probably the twelfth of a grain) of atropia hypodermically, gave hypodermic injections of a solution of the extract of physostigma (quantity not mentioned). The patient recovered.

ATROPIA FOR THE PAIN OF CANCER.—Auger (*Edinburgh Medical Journal;* from *Union Médicale*) uses a lotion of 1 part in 1000 of sulphate of atropia, applied by means of a compress wetted with the solution and covered with oil-silk. This gives considerable relief to the pain of cancer without causing dilatation of the pupil or dryness of the throat.

MISCELLANY.

REQUEST FOR SPECIMENS OF SUSPECTED WATER.—Dr. J. W. Mallet, of the University of Virginia, has undertaken, by order of the National Board of Health, a careful study of the chief methods in use for the chemical examination of potable water, so far as organic matter is concerned. It is particularly requested of the correspondents of the Board, of medical men throughout the country, and of others interested in sanitary matters, that any well-marked case of disease which may seem on medical grounds fairly attributable to organic impurities in drinking-water be promptly reported to Dr. J. W. Mallet, University of Virginia Post-Office, Albemarle County, Virginia, with a few lines stating clearly the medical nature of the case and the character of the evidence on which the water in question is suspected of having actually caused disease in persons who have used it. It is further desired that a sample of each such water be forwarded for examination, *but not until notice has been received from Dr. Mallet that the analysts are ready to proceed with it*, since it is important that no useless delay should occur between the shipping of the sample and its investigation in the laboratory. In notifying any one who may be able to furnish specimens of suspected waters that may be forwarded, clear instructions will be sent as to the quantity of water required, and the mode of collecting, packing, and shipping it. It is particularly desired that no case be presented on doubtful or vague evidence, since one important object of the inquiry demands that all such be rejected, and only those cases examined which involve the strongest grounds for believing that mischief has really been caused by organically foul drinking-water.

The cost of packages and transportation for samples will be borne by the Board of Health.—*National Board of Health Bulletin.*

SANITARY EXHIBITION IN NEW JERSEY.—The New Jersey State Fair, to be opened at Newark on September 19, is to have a sanitary annex, as it has had for the two previous years. It is intended to make an attractive exhibition, so that visitors to the Fair may become acquainted with the best sanitary arrangements and inventors and dealers have a good opportunity for comparing and testing apparatus. An abbreviated summary of articles to be exhibited is given in the *National Board of Health Bulletin* for July 9. It comprises construction materials, furniture, wall-paper, etc., heating and ventilating apparatus, drainage and water-supply, bathing apparatus and bath-room fixtures, with gas and other lighting apparatus, druggists' samples and preserved foods, excavating and odorless apparatus, life- and labor-saving apparatus, gymnasium apparatus, sick-chairs and beds and sick-room appliances, food-adulteration and testing apparatus. Letters of inquiry may be addressed to E. A. Osborn, C.E., Middletown, N.J., or to State Board of Health, Trenton, N.J.

ENTERPRISING SURGERY.—The rage for "bold" and "daring" operations seems to have taken complete possession of the German surgeons. Dr. Zeller, of Berlin, proposes to open the trachea as a prophylactic measure during operations, and Dr. Gluck has carried out successfully the complete removal of the bladder and prostate in dogs, and hopes before long to do the same in the human subject.

DEATH OF PROF. PERLS.—The University of Giessen has sustained a severe loss by the death, on May 15, of Dr. Max Perls, Professor of Pathological Anatomy and Director of the Pathological Institute. His fame chiefly rests upon his "Allgemeine Pathologie," completed in 1879.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM JULY 24 TO AUGUST 6, 1881.

HUBBARD, VAN BUREN, CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for four months. S. O. 169, A. G. O., July 26, 1881.

KING, WM. H., CAPTAIN AND ASSISTANT-SURGEON.—Now awaiting orders at Greencastle, Pa., to report in person to Commanding General, Department of the East, for assignment to temporary duty. S. O. 171, A. G. O., July 28, 1881.

TORNEY, GEO. H., CAPTAIN AND ASSISTANT-SURGEON.—The leave of absence granted him from headquarters, Department of the Missouri, June 21, 1881, extended one month. S. O. 76, Military Division of the Missouri, July 25, 1881.

GARDNER, EDWIN F., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Relieved from duty in Department of Dakota, to proceed to Eastport, Me., and on arrival there report by letter to the Surgeon-General. S. O. 171, c. s., A. G. O.

GARDNER, EDWIN F., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—The operation of paragraph 3, S. O. 171, c. s., A. G. O., in his case, suspended one month. S. O. 177, A. G. O., August 4, 1881.

PHILADELPHIA, AUGUST 27, 1881.

ORIGINAL COMMUNICATIONS.

NEURASTHENIA.*

BY ANNA HAYWARD JOHNSON, A.M.,
Orange, N.J.

DEFINITION.—"Neurasthenia is a chronic functional disease of the nervous system, the basis of which is impoverishment of nervous force, waste of nerve-tissue in excess of repair; hence the lack of inhibitory or controlling power, physical and mental, the feebleness and instability of nerve-action, and the excessive sensitiveness and irritability, local and general, direct and reflex. The fatigue and pain that temporarily follow excessive toil or worry, or deprivation of food or rest, are symptoms of neurasthenia from which the chronic form differs only in permanence and degree. Nervousness is really nervelessness."†

Drs. Beard and Stretch Dowse both, to some extent, divide the general neurasthenia into cerebrasthenia (brain exhaustion) and myelasthenia (spinal exhaustion). As it is very doubtful whether one condition can exist without the other, I will consider them together simply as neurasthenia.

Stretch Dowse says, "There are many physicians who attribute the symptoms of neurasthenia to a bloodless condition of the brain or spinal cord. I am quite sure that this opinion is incorrect and cannot be supported by any trustworthy doctrine."‡

Beard says that neurasthenia is generally confounded with general anæmia.

Causes.—Anything that will induce expenditure of nerve-tissue without an equal storing up of new material will necessarily cause nerve-exhaustion. Super-activity and development of the nervous system must, without doubt, be the primary cause of such a condition. Civilization, consisting as it does in a sovereignty of the nervous and mental over the purely muscular and animal activities, can therefore claim as an outgrowth neurasthenia.

It is pre-eminently a disease of American civilization; for, whatever may be the cause, the fact is undoubted that American life consumes nervous force more rapidly than that of any other nation. Adult Americans of the upper and middle classes, as a rule, live on the principal, not the interest, of their strength.

Dr. Van Deusen, Medical Superintendent of the Michigan Insane Asylum, says, "Among the causes, excessive mental labor, especially when conjoined with anxiety and deficient nourishment, ranks first. Prolonged exposure to a malarial region may induce it; also great responsibility, with deprivation of sleep."

Dr. Stretch Dowse emphasizes the "heredity of nervous constitutions, which are especially liable to exhaustion and fatigue," as a predisposing cause of neurasthenia. Dr. William Erb says it generally occurs in neuropathic families. Stretch Dowse also says, "I believe that many severe cases of exhaustion of the brain are brought about by not paying sufficient attention to sleep and rest. Excessive fatigue, overwork, worry, sensuality, mental anxiety, shock, grief, are among some of its most important causes."§

"Professional men, and especially clergymen, seem to be more prone to these attacks than others, and it is not an easy matter to assign any especial reason for this. It is quite certain, however, and I believe it is a generally-admitted fact, that the performance of constant routine work without adequate change exercises, although perhaps inexplicably, an undue tension upon the nervous system and nervous centres, which in course of time leads to instability and exhaustion." The law of nature demanding to a certain extent equal development of all the faculties might suggest an explanation of this result.

So-called "cramming" is a potent cause. Stretch Dowse speaks thus strongly: "It is simply a blot upon advancing civilization. It is opposed to all biological laws,—social, moral, hygienic, ethical, physical, and rational."‖

Local diseases, especially of the digestive and of the reproductive organs, are frequent causes. They act as constant irritants to the nerve-centres, and reflexly on the whole nervous system. Sexual excess and abuse are powerful and frequent causes of many of the worst forms of neurasthenia; al-

though Dr. Van Deusen's experience has led him to an opposite conclusion. Long-continued strain from optical defects has, within a few years, been recognized by those highest in authority as a very frequent cause of nervous exhaustion.

Method of Examining Cases.—We see from the definition of the disease that its symptoms must be largely subjective. The patient and physician must, in the highest degree, work together. The physician necessarily has only the statements of the patient with regard to many symptoms, as data from which to diagnose the case. Knowing how few people can be perfectly truthful witnesses on subjects of special interest to themselves, we must expect to give unwearied patience to eliciting testimony of a subjective and also pathological character. "The effect of this scientific analysis of cases is not to make our patients hypochondriacal, but to remove their hypochondria. The worst enemy of the emotions is the intellect." (Beard.)

As a knowledge of the condition of the different organs is necessary, we must often have the aid of skilled specialists, as oculists and gynæcologists.

Symptoms.—I have found it impossible to classify the symptoms. I will, therefore, follow Dr. Beard's method of describing those of the head first, and going down to other parts of the body. Many of these symptoms I have seen; others I find described in the works of Beard, Stretch Dowse, Beard & Rockwell, Dr. Van Deusen, and in the writings of Bartholow, Flint, Niemeyer, Fothergill, and others. By the latter they are often considered as idiopathic diseases, or as symptoms of structural trouble. Only wide experience could enable one to decide between these conflicting theories.

Tenderness of the Scalp.—Dilatation or Abnormal Activity of the Pupils.—Inequality of the pupils is also a symptom of structural brain disease, but in that case the transitory character of a neurasthenic symptom is wanting.

Sick-Headache.—In certain cases this is the most troublesome expression of the neurasthenia. Fothergill says that in cerebral exhaustion the pain may be frontal, parietal, vertical, or occipital. According to Beard, attacks of sick-headache are safety-valves, preventing other nervous symptoms. Sudden cessation of attacks of sick-headache, without some improvement in the general condition, may, it is said, be the forerunner of severe structural lesions. They are apt to cease after fifty years of age.

Flint evidently directs his treatment of sick-headache to nerve-exhaustion. Niemeyer says that it is often caused by "mental excitement." To have a pathological effect, excitement must be over-excitement, which in this case would mean mental or nervous exhaustion.

Pain, Pressure, and Intense Heat of Vertex.—Symptoms particularly found in the exhaustion of the nervous system attendant upon the menopause, but not confined to that condition.

Expression of the Eyes.—Congestion of Conjunctiva.—Disturbances of Nerves of Special Sense.—Here we have "asthénopie asthénique," showing in the most thorough examinations no lesions sufficient to cause the attending symptoms. Weir Mitchell says he very seldom meets cases of nervous exhaustion without this symptom. Specks, bright flashes, and shadows before the eyes often accompany a slight form of nervous exhaustion. In one case which I have seen, these symptoms come on to a distressing extent after exhaustion amounting only to ordinary fatigue. Subjective noises,—a crackling in the ears, sometimes preceded by numbness amounting to partial deafness. Subjective odors and idiosyncrasies of the sense of smell. A weak or atonic voice.

Deficient Mental Control.—An inability to keep the mind fixed on a given subject: abnormal forgetfulness. The patient, while endeavoring to concentrate his thoughts on a matter that may be of intense interest to him, suddenly finds that he is in the midst of a waking dream. Sometimes the thought of brain-work bringing with it responsibility causes an utter inability to follow a connected line of thought. The patient even after repeated re-readings of a paragraph is unable to retain the slightest idea of its subject. Is not the entire lack of profit from hours of close study done by many students, medical as well as those who are expected to know less of hygiene, caused by this condition? "They find the brain is master and not themselves."

Mental Irritability.—Analogous to the lack of mental control, indeed only a different manifestation of the same symptom, is mental irritability. This is often

the natural habit of mind, irritability and general "total depravity" of temper; but a differential diagnosis can be made with comparative ease.

Hopelessness. — "An instinctive consciousness of inadequacy to the task before us." (Beard.) In organic diseases the opposite condition is apt to exist, and in neurasthenia the presence of this symptom would largely depend on the state of mental control of the patient, and on a clear understanding of his own case. It is a distressing symptom, which ought to be quickly ameliorated by a wise physician.

Morbid Fears.—Until recently the various forms of morbid fear have been considered as hysteria, hypochondria, dyspepsia, biliousness, or even insanity. If accompanied by delusions, they are found in insanity. Drs. Beard, Erb, Westphal, Weir Mitchell, and others, have recently diagnosed them as symptoms of neurasthenia. "The patient knows there is no just objective ground for his fear, but his emotional nature, under the influence of his exhausted nervous condition, overcomes his reason and will." (Beard.) The same author says they are never found in structural nervous disease. Niemeyer and Fothergill, though making no such assertion, lead negatively to the same impression. One form of fear, pathophobia, or fear of disease, is of particular interest to us. Authors differ as to the cause and nature of what most of them consider the disease of hypochondriasis. Beard classes under pathophobia only those cases in which the symptom is recognized by the patient as being merely morbid fear: where there are delusions and hallucinations he calls it insanity. Flint says that, although a mental aberration, it does not amount to insanity. He recognizes the two classes. Although considering it an idiopathic disease, he says, "The morbid conditions often existing in hypochondria and more or less concerned in its causation are various. Among these may be mentioned anæmia, *nervous asthenia*, and dyspeptic disorders." Niemeyer calls it insanity, and speaks of only one class of cases, those in which there are delusions.

Fidgetiness. — This, like specks and flashes before the eyes, may be a habit of life; but even then it is a symptom of nerve-exhaustion, occurring when the patient is fatigued or over-strained from lack of sleep. In one case under my observation it comes on severely during the night, preventing sleep, and is only relieved by vigorous rubbing.

Insomnia.—This condition, reacting as it does on its cause, by preventing one of the most important factors of nutrition,—*rest*,—deserves especial attention. Sleep is probably caused either by a physiological anæmia of the brain, or, according to Foster and other physiologists, by purely molecular changes in the brain, the accompanying anæmia being an effect. In accordance with the first theory, neurasthenia would act to produce sleeplessness by causing vaso-motor paresis, thus bringing about dilatation of the cerebral vessels. If the second be correct, as the character of the "purely molecular changes" is unknown, so would be the exact change caused by nerve-exhaustion. Reference to different authors leaves us in no doubt as to the existence of insomnia arising from neurasthenia, although the explanations of the condition are various.

Drowsiness.—This may be a demand of the system for more sleep. Dr. Van Deusen says there is often a functional derangement of the kidneys, as evidenced by a marked increase of urea in the urine. The drowsiness he attributes to this cause.

Nervous Dyspepsia.—In many cases this is the first noticeable symptom of the neurasthenia. It is diagnosed from other dyspepsias by these peculiarities: it is temporarily relieved by eating; it accompanies other nervous symptoms; it yields readily to nerve tonics, the bromides, and electricity. Stretch Dowse speaks of severe flatulent dyspepsias the result of anxiety and worry.

Deficient Thirst, and Inability to Assimilate Liquid.—The body contains 87 per cent. of water. The amount used by a healthy man in twenty-four hours is about eighty ounces. Any condition which would cause the supply to fall much below this normal standard must necessarily act seriously on nutrition. It tends towards "mummification." "A mummy, which is the body of a man minus water, is a very different thing from a body containing its natural proportion of water." (Dr. Meigs on "Thirst.")

Desire for Stimulants and Narcotics.—The craving of body and mind for anything that will give strength and ease leads in a large number of neurasthenic patients to confirmed inebriety and opium-

eating. Drs. Beard and Stretch Dowse consider this the principal cause of the great increase of opium and alcohol drunkards.

Abnormalities of Secretion.—There is in some cases dryness of the skin, in others excessive secretion, both due to lack of normal stimulus from the governing nerves. The latter is often very troublesome, sometimes general, more often confined to hands or feet.

Spinal Irritation.—This accompanies other neurasthenic symptoms in not a few cases. It is generally considered an idiopathic disease; but the strongest arguments are certainly in favor of its being a symptom of neurasthenia.

General Hyperæsthesia.—This frequently takes the form of sore spots over the superficial bones. It is interesting to note, in this enumeration of symptoms, how many of them we experience ourselves, in less degree, as sequences of fatigue (acute neurasthenia).

Pain, Aching, and Heaviness in the Loins and Legs.—Beard says that sometimes there are present severe, lightning-like, shooting pains, simulating those characterizing locomotor ataxy. Stretch Dowse has been led to a different conclusion. The cases in which this symptom was present have, in his practice, proved that sclerosis of the cord was commencing.

Podalgia, or Pain in the Feet.—One case that I have seen has had, for two years, severe pain in the anterior portion of the ball of one foot. We would expect to find an *Irritable Heart* in this general lack of nervous power. There is often a self-diagnosis of heart disease.

Tremors of Certain Muscles.—This has in one case under my observation become chronic in the muscles of one side of the face. Niemeyer says the course of *tic convulsif* is usually chronic. Beard thinks that chronic cases are generally due to some organic lesion. Analogous to the last symptom are *convulsive movements on going to sleep.* This is another symptom often seen in acute neurasthenia, or fatigue.

Cramps.—Beard attributes the cases of so-called idiopathic cramp, as "scrivener's spasm," etc., to neurasthenia. Niemeyer says "we are unable to point out the anatomical cause," and further on speaks of the "occurrence of muscular spasms during the course of and convalescence from acute and chronic disorders which have an exceedingly pernicious effect upon the assimilation and nutrition of the body." Such cases certainly point to neurasthenia as a cause. These patients are subject to *special idiosyncrasies*,—great sensitiveness to heat or cold, or to certain articles of food or medicine. I have seen several cases in quite good health who, at times, cannot put their hands in cold water without the fingers turning white and numb. There is also a general sluggishness of the circulation, due apparently to lack of vasomotor tone.

Tendency to "go to sleep," or to a localized numbness, is almost always present. The arms, or more frequently but one, may become numb simply from pressure on the bed, waking the patient with the feeling of weight and discomfort.

Profound exhaustion coming on suddenly without apparent cause, *excessive ticklishness, itching, general and local chill and heat,* and nervous chills closely simulating regular malarial paroxysms, are not infrequent.

Neuralgia.—The neuralgias in many forms are often present. They differ from what we might call structural neuralgias in their almost constant change of position.

Beard and Stretch Dowse emphasize the fact that all of these symptoms, and indeed many others, are often present in individuals having the appearance of vigorous health. It is very important to realize that severe neurasthenia is compatible with great muscular development and physical endurance.

Differential Diagnosis.—The importance of making a correct differential diagnosis between functional and organic nervous disease cannot be overestimated. In general, prognosis and treatment are directly opposite. It necessarily is extremely difficult, since many of the symptoms are identical. In the majority of cases only prolonged study of them will enable the most experienced physician to feel sure of his diagnosis. I think Dr. Beard strikes the key-note of diagnosis when he says, "The tendency of neuropathology is not toward but away from the idea of single pathognomonic symptoms. It is by considering groups of symptoms in their relation to each other and to the history of the case" that a diagnosis can be made. Structural as well as functional nervous troubles must of course be perfectly familiar to the physician.

Dr. William Erb says, in speaking of

diagnosis, "The decision will be based chiefly on the great disproportion between the acute subjective complaint of the patient and the almost negative result of objective examination." (Ziemssen, vol. xiii. p. 378.) Dr. Beard gives four general points which I think would be of use to one entering upon the study of this class of cases. They are:

1. The symptoms of organic disease are usually fixed and stable, while very many of those of neurasthenia and allied states are fleeting, transient, metastatic, and recurrent.

2. There are certain, though not well-known or always recognized, symptoms of neurasthenia which do not often, if at all, appear in structural disorders. Among these are general and local tenderness, fidgetiness, sick-headache, asthenopia, flushing, morbid desire for stimulants and narcotics, hopelessness, hypochondria, and morbid fears.

3. In organic disease reflex activity is generally diminished; in functional disease reflex activity is generally increased. This accounts in part for the immense number and variety of symptoms from which the neurasthenic suffer.

4. Neurasthenia and allied troubles are most likely to occur in those in whom the nervous diathesis predominates.

Stretch Dowse puts in the category of probable organic cases many of those showing the more severe symptoms which Beard considers purely functional. The necessity for endless study and experience cannot be too strongly insisted on.

A differential diagnosis must also be made between cerebrasthenia (brain exhaustion) and myelasthenia (spinal exhaustion). This has not yet been satisfactorily done. Stretch Dowse thinks that one condition cannot exist without some degree of the other. This seems highly probable. Still, it is necessary to recognize, if possible, which condition predominates. Neurasthenia must also be differentiated from its allied affections, as hysteria and the like; from anæmia; from certain manifestations of syphilis and various other organic lesions not primarily nervous.

Prognosis.—Favorable under proper treatment, according to Drs. Beard, Weir Mitchell, Erb, Van Deusen, also, to a more limited extent, according to Stretch Dowse. It depends largely on the hereditary diathesis of the patient. Dr. Van Deusen says, "We cannot but regard the early recognition of this condition as of special importance, convinced that properly-directed treatment will, in the majority of cases, stay its progress." Whether we shall be obliged to give a prognosis of organic lesions is a point on which authorities differ. Stretch Dowse says, "I have no hesitation in asserting it to be my firm belief that many of the incurable cases of insanity, locomotor ataxy, progressive muscular atrophy, and many other diseases of the brain and nervous system, commence as a neurasthenia of nervous centres, and when in this state are quite amenable to treatment." Beard does not entirely agree with him, and still cannot deny that "neurasthenia neglected, exasperated by bad hygiene or by bad treatment, may be the precursor of certain forms of insanity." The list of possible sequelæ is as long as a knowledge of the essential nature of the disease would indicate. It is comforting to know that most of them follow *neglected* neurasthenia. The most serious are the following: insanity, especially in the form of melancholia, hysteria, congestion of the kidneys in various forms, exophthalmic goitre, diseases of the reproductive organs and other animal functions, may all be found following neglected neurasthenia, inebriety, and opium-eating.

Treatment.—The two general indications for treatment are want of rest and of nutrition. More accurately speaking, rest is only one means of securing nutrition, but for convenience I shall consider treatment under the two heads.

Rest.—I speak of this first, because I believe that without it all the dietetic and therapeutic measures which could be planned and carried out by a world's congress of physicians would be of no avail. Its attainment is in all cases the first consideration. Symptoms may be ameliorated, but a cure cannot be made without it. By rest, I mean all degrees, from the absolute seclusion and rest as sometimes practised with almost marvellous success by Drs. Weir Mitchell, Charcot, Goodell, and others, to simply removing the cause of over-strain of the nervous system. The former extreme measures are particularly indicated in cases where certain mental characteristics of the patient or of his friends, or certain conditions of home life, render it impossible to attain real rest without them.

The latter equally extreme could only be indicated where the nervous exhaustion is beginning, and the recuperative power of the patient still capable of doing some extra work. The first thing to be done under all circumstances, if possible, is to remove the overwork, anxiety, or mental strain which is present. Of course, by overwork I mean work that is over or above the amount easily accomplished by the patient in his present condition. Mind and body must be put at rest. What constitutes this rest can only be decided in each individual case. One point of great importance in treatment is that no two cases can be treated alike. Each is a study in itself. It must often be very difficult to bring about this necessary change in nervous work, because these very anxieties, responsibilities, and strains of the nervous system are generally so intimately woven in the texture of the daily life of our patients. It will require, on the part of the patient, perfect confidence in the physician; on that of the physician, power to read the moral and mental as well as physical character of the patient, great delicacy of mental touch and expression, and fine tact. Under the question of rest comes that of travel. Such patients are often advised to travel; but it is almost invariably worse than useless. It is, while travelling, impossible to have the regularity in rest, sleep, and food which is of so much importance in these cases, as Stretch Dowse says. Besides that, the meeting strange people, the unseen friction kept up between human beings, is a constant drain on the nervous system. The sight-seeing and intense interest awakened by change of surroundings, though serving to keep the patient's mind off himself, use a large amount of nervous energy. The only kind of travelling that would seem adapted to this class of cases would be long sea-voyages taken under favorable circumstances. The subject of climatic influence might properly be considered here. Stretch Dowse advises cold, bracing, dry climates, never warm ones. He speaks particularly of the valley of the Upper Engadine as being well adapted to neurasthenics. Beard prefers cool mountain-air, but says that warm climates often act as well in these cases as in phthisis. That they should do so seems reasonable, for in them the body is put more entirely at rest, less nutritive energy being required to keep up the normal temperature.

A special and exceedingly important means of securing this necessary rest is the relief of that too common symptom, sleeplessness. We must give the patient sleep in some way. If the symptom quickly yields to the general treatment of the neurasthenia, the case is a very hopeful one. But we cannot wait too long for this result of general treatment. In speaking first of the simple and, if successful, better measures to induce sleep, easily-digested food taken on retiring is one of great value. Half a glass of milk, with a little sherry or whisky if alcohol is well borne, or a glass of Bass's ale, will often insure a good night's rest. While exercise in the evening is one of the best soporifics for the healthy man, the neurasthenic patient is still more exhausted and his trouble increased by it. Drs. Beard and Rockwell have found that electricity, not applied with special reference to this symptom, almost invariably exerts a beneficial influence. "The temporary relief, though far less potent than that of bromide and chloral, is decided. The permanent relief comes gradually and slowly, but surely." The bromides may be resorted to in some cases, or chloral, or opium. Stretch Dowse depends largely on opium, not only for the relief of this symptom, but for the general treatment of neurasthenia. Hammond has found that in some cases the upright position will induce sleep. This, of course, would be where cerebral hyperæmia was present. The physician's ingenuity must often be taxed in combating this symptom, and here, as everywhere, experience is of incalculable value.

Nutrition.—Under this head I will consider the remaining points of treatment,—viz., diet, drugs, and general hygiene.

Diet.—In ill health the natural instinct of hunger as a demand of the body for needed nutriment cannot be relied on. The patient must be guided by certain rules, and, as Dr. James Henry Bennett says, "Those rules which guide us in ill health must be founded on a knowledge of what occurs in health." He says, "The popular idea with regard to food in ill health that it is synonymous with strength is a fallacy and a delusion." The actually accomplished elaboration and assimilation of the food taken is synonymous with strength. The principal indication under diet is to give all the nutrition which is

required to restore the body to perfect health, and to give this in such form and manner as to use as little force as possible in accomplishing the desired end. We must, therefore, give the most easily digested and nutritious food in as large quantities as the system will assimilate. Stretch Dowse feeds some of his patients every hour, with no reference to the kind of food taken. A varied diet is generally best, although the so-called milk-diet, as tested especially by Weir Mitchell, is applicable to some cases. The whole milk is best, where it can be digested, for, as Beard says, one of the great wants of the day is an increase of fat in the food. Remembering that animal food is more condensed nutrition than vegetable and should therefore be the principal, but, except in certain cases, not the sole, article of diet, that, as James Henry Bennett says, "Density of structure is one of the principal conditions that regulate the digestibility of both animal and vegetable food," and that the digestive system requires a certain amount of absolute rest, we have the general principles from which to develop special plans of diet for individual cases. Where there is overfeeding, the urine betrays it by an abnormal precipitate of urates.

General Hygiene.—"If we analyze the fundamental laws of hygiene, we shall find that they are all subservient to perfect nutrition,—indeed, are inseparably connected with it." Exercise, physical and mental, air, light, and clothing, are important elements of treatment. The question of exercise, from the massage used in the "rest cure," to vigorous mountain-climbing for a slightly exhausted brain, must be decided for each case. Fatigue must in all cases be avoided. In all forms of exercise, remember that to a certain extent slow movements build up, fast ones tear down. In many cases some degree of mental work is advisable. An occupation that will combine pleasant recreation and useful work will best meet the indications. For perfect nutrition we must have plenty of oxygen. Let the patient live in the country if possible; at least the dwelling-house must be well ventilated, and the sleeping-room supplied with air, pure, though not too cold. During sleep the skin is relaxed, and the general power of resistance reduced to its lowest terms, so that the temperature of the room should not fall many degrees below that of the day. Let him have all the sunlight possible. Dr. Edward Smith, of Brompton Hospital, England, has found that under the influence of sunlight one-third more air enters the lungs than in darkness or artificial light. Under hygiene would perhaps come a form of treatment called by Weir Mitchell "camp cure." I know by experience that modified forms of this life will in many cases secure favorable results.

Clothing must be thoroughly loose, light, and warm. Too much clothing is debilitating. Cold or tepid sponging and modified massage will do much towards keeping up the heat of the body.

Drugs.—Nerve tonics are of course principally indicated. Van Deusen has found quinine the most efficient; but his experience has been in a malarial district. Stretch Dowse depends largely on opium. Beard ranks opium with chloral and alcohol as of value, but much overused and attended with danger. He uses electricity,—hardly a drug, but certainly a nerve tonic,—ergot, arsenic, cannabis indica, caffeine, zinc combinations, the latter particularly useful in choreic manifestations. Bromides in large doses for a short time.

Weir Mitchell uses iron in many cases. Cod-liver oil is often of much benefit. Although electricity has in different hands given varying success, the best results have been with those who have used it most scientifically and thoroughly. Phosphoric acid and the phosphates, also extract of malt, are often good remedies.

It is an almost invariable rule that all remedies are more effectual in this condition if frequently changed or stopped. For instance, sedatives one week, tonics the next, then perhaps nothing for a few days. This plan has been thoroughly tried by Dr. Beard, and in some cases under my observation remedies used in this way have acted satisfactorily that could not have been taken for any length of time continuously.

There is still a wide field open for investigation in the special sequence of remedies, as indicated by the sequence of symptoms in the disease; for, although treatment must always be directed to the general condition, different remedies have almost specific actions in the different stages or manifestations of the disease.

We owe our knowledge of neurasthenia very largely to Dr. Beard, and, as he says, one might graduate from all of our colleges, be well read in general medical literature, and have had dispensary and hospital experience, without having learned anything of this wide-spread, American, functional nervous disease. If it increase in the future as it has in the past, keeping step with civilization, we can comfort ourselves with knowing that, notwithstanding the truth of the above statement, the medical profession are recognizing the existence of such a condition, and that greater advance has been made in this direction in the past quarter of a century than in almost any other department of medicine.

CLINICAL NOTES OF A CASE OF TWIN PREGNANCY.

*Read before the Philadelphia County Medical Society, March 9, 1881,**

BY ALBERT H. SMITH, M.D.

IN bringing this case before the Society it is not proposed to exhibit a unique case, nor one which would be at all extraordinary in its features to the active obstetrician, but merely to present to the general practitioner a case combining a number of features for study, which may impress upon the mind some important points in obstetric theory and practice.

In September last I was called to see a patient in the eighth month of gestation, her last menstruation having ceased January 24 preceding. It was her sixth pregnancy, and during each she had been the subject of much gastric and neurotic disturbance, and at the end of all, except one, delivered by forceps with some difficulty, in the second by craniotomy. During the present pregnancy her general discomforts, and especially her gastric disturbances, had been extraordinarily great, the whole summer and the latter part of the spring being passed in continuous nausea, frequent vomiting, great epigastric distress, sense of abdominal tension, anorexia, invariable suffering after eating, variations between obstinate constipation and profuse diarrhœa, and, as she described it, an utter *malaise* and moral depression, which unfitted her for the enjoyment of all social and family relations and disabled her from the performance of the ordinary domestic duties. As I was absent from home, and she regarded these conditions as merely incident to an advancing pregnancy, she consulted no one about them, took such little palliatives as her past experience suggested, and waited patiently in suffering until my return.

On the 7th of September I was sent for to see her, and found her in a really alarming condition, although not aware herself of the seriousness of her ailments. Up to this time she had been out of town, and came in to see me, expecting to return at once; but her condition was such that I insisted upon her remaining quietly at her house, away from the cares and annoyances of family duties, and so that I could have her under constant observation.

When I first saw her, she was anæmic, waxy, œdematous over her whole surface; the legs greatly swollen, and the hands and face much so, and the whole body presenting marked evidences of anasarca. The pulse was 110, feeble, and quick; the skin dry and harsh; the tongue with a slight fur upon the back part, but elsewhere intensely red, with a marked development of the papillæ, and its surface traversed by deep fissures running longitudinally, very sensitive, painful to the touch or upon motion in the mouth or in the effort at protrusion, and causing her such great distress in eating that she had abandoned the use of solid food from necessity, as well as from disgust for it. Her appetite was altogether gone, and she was living on milk and beef-tea from a sense of duty rather than from any sense of need. Nausea was almost constant, and vomiting very frequent. Epigastric pain and tenderness were marked, and the peculiar feeling of distress in the pit of the stomach, that indescribable, vague sensation so characteristic of the uræmia of pregnancy, was added to the many other discomforts. The bowels were obstinately constipated, the saline and other laxatives being required in large doses to have any effect. Locomotion was very slow and difficult, partly from a muscular soreness, and partly from the very great abdominal distention, with its attendant embarrassment and awkwardness. Dull headache was persistent; drowsiness during the day and wakefulness at night

* This paper has been unavoidably delayed, and consequently appears at a later date than the other papers read at this meeting.

habitual. Vertigo and dizziness often compelled a sudden resort to the recumbent position; and during these attacks the characteristic retinal perversions would cause great alarm,—the field of vision being limited sometimes by a vertical line, sometimes by a horizontal, and sometimes the sight completely lost. Numbness and loss of tactile sense in the fingers, and occasional loss of distinct articulation, were experienced. Altogether, the symptoms attendant upon marked renal trouble were about as decided as often seen. The urination was frequent and scanty.

Upon examination of the urine, it was found by heat and Heller's test to contain fully three-fourths of its bulk of albumen, —by the former, some specimens completely solidifying in the test tube.

I placed the patient at once upon an active course of purgative, diuretic, and tonic treatment, varying the remedies from time to time according to the indications presenting. Under the influence of iron and quinia, her tongue became less sensitive, and lost to some degree the condition above described, so that she was able to take food with rather more comfort; a pill of podophyllin, with nux, aloes, and Tyson's antimonial powder, taken at night, kept the bowels regulated; sodium bromide abated the nervous and cerebral symptoms and relieved the sleeplessness. The diuretic measures were, however, of no avail; digitalis, the alkalines, the old and admirable combination of calomel, squill, and digitalis of the first Dr. Pepper, Basham's mixture, and other ordinary renal evacuants, called forth no response from the kidneys. Benzoate of sodium was followed by a slight increase in the secretion, but no diminution perceptibly in the albumen.

On the 2d of October I decided to try a combination of benzoic acid and lime, basing my hope of gain upon the reputation of the benzoic acid, so confidently recommended by Prof. Charles D. Meigs, and some excellent results I had had formerly from large doses of lime-water in Bright's disease, following the suggestion of some Belgian physician, whose name I cannot now recall. I had Mr. Shinn prepare me a combination of benzoic acid with carbonate of lime, triturated with a little water until effervescence ceased, in proper proportion to form a calcium benzoate, and the resulting paste was placed in Planten capsules, divided into about ten grains each, and was administered in this dose every two hours during the day, beginning in the early morning and continuing till bedtime, so that about eighty grains were taken daily. The result of this treatment was successful beyond my expectation. The laxative pill and the use of the bromides when needed were still kept up, but all other treatment suspended. The amount of urine increased steadily from day to day, and the amount of albumen steadily diminished, until by the 12th it had entirely disappeared. And in proportion to the renal alteration was a change in the general condition and the special symptoms apparent, so that by the time the albumen had disappeared, the only marked signs of disturbance were those necessarily present from the great abdominal distention and pressure upon underlying organs. On the 13th, feeling so much better, and having become disgusted with the constant daily administration of the capsules, the patient begged to be let off from them, to which I consented. For some days there was no decided deterioration of condition; but five days later I saw her, and found that the œdema was decidedly increased, and all the special distresses aggravated, and that she was fast returning to the state first described. On examination of the urine, which had diminished very much in quantity and was more frequently voided, I found the albumen again developed by the tests, though in very much less amount than before. I placed her again on the use of the salt of calcium, which by this time Mr. Shinn had prepared in a separate, beautifully crystallized form, which was found to be soluble to the extent of ten grains to the tablespoonful of water. The same dose was given, and I had the satisfaction of seeing the albumen again disappearing, with the same proportional alleviation of general and special symptoms. On the 22d the patient fell in labor, and the whole combination of ailments rapidly disappeared after her delivery. Not feeling warranted by her condition in insisting upon catheterizing her to examine the water free from any lochial discharge, I had no opportunity of getting it until about the twelfth day, when all signs of albumen failed to be detected.

We will now return to the conditions of the pregnancy which may be regarded as the legitimate causes of these many troubles.

On the 27th of September I made a preliminary examination by abdominal palpation, as is my custom during the last month of gestation in the case of all pregnant women under my exclusive care, to ascertain the positive presence of a fœtus and its relation to the uterine cavity. I soon detected the signs of a twin pregnancy; the great size of the abdomen, its peculiar shape apparent to the eye, irregular and flattened in the median line, would give ground for suspicion. But upon careful abdominal examination the fact became fully established, palpation showing the presence of distinct bodies, with the four large extremities, two near the pelvic entrance and two near the fundus. A firm mass, recognized by its impression given to the hands grasping it between them from side to side as a fœtal head, lay immediately above the brim; the fingers of the left hand, with their tips pressed towards the brim in the left groin, came upon the prominent abutment formed by the chin, while the fingers of the right hand could trace the continuous dorsal plane from the occiput along the nucha and back of the fœtus till it reached the breech in the right lateral region of the uterus below the fundus; from this mass passing towards the median line of the abdomen were easily recognized the thighs and legs, their mobility and outlines being readily distinguishable through the central abdominal wall. But above these, again, towards the fundus, to the left of its median portion, was detected another large mass, whose round, uniform surface and firmness on compression showed it to be another fœtal head, from which a dorsal plane could be traced downward upon the left side, looking anteriorly and terminating above the left groin in the larger but more compressible mass of the breech; the lower extremities of the fœtus were not so easily appreciable, being directed posteriorly and a little behind the body of the first discovered. Auscultation gave two points of maximum intensity to the fœtal heart-sound,—one upon the right side of the median line below the umbilicus, and the other far over beyond the median line upon the left and a little above the umbilicus. I had thus a clear evidence of the presence of two fœtuses, which upon pressure in the median line of the uterus could be entirely isolated,—the one presenting with its head towards the pelvic brim and its dorsum lying posteriorly and to the right, the other with its head near the fundus, its dorsal plane towards the left side anteriorly, the breech under the left groin. The maternal *bruit* was not clearly distinguishable. The patient fell in labor on the morning of the 22d of October, at two o'clock A.M. I saw her at four o'clock, the os being about half open; a head was presenting well down in the brim, with the occiput posteriorly to the right. Abdominal palpation showed no change in the condition previously diagnosticated. At five o'clock A.M. the water discharged, and ten minutes after the fœtus was expelled. Knowing that there was another fœtus, I did not leave the ligation of the cord, as usual, till after the delivery of the placenta, but tied it in two places, cutting between as a precaution against possible bleeding from intercommunication of the two placentæ. On digital examination I found the cervix reconstructed, instead of the flaccid dilated condition found after the expulsion of the fœtus in an ordinary simple pregnancy, there being a firm closed conical neck restored, with about half dilatation; the presenting part of the second fœtus was entirely out of reach. Abdominal palpation revealed a transverse position of the child, the head lying in the right iliac fossa, the breech in the left. The membranes being still unbroken, I easily corrected the deviation. Standing with my back to the patient's face, my right hand made firm but gentle pressure above the right groin upon the head-globe downward and inward towards the median line. At the same time pressing the flat palm of the left hand below the prominence of the breech in the left groin, with its whole surface applied firmly but gently, I made an oblique pressure upward and inward, with a slow vermicular movement, which caused the breech gradually to ride up upon the left uterine wall, as upon an inclined plane, until it reached a point about the middle of the long axis of the uterus, when it slipped quickly upward, and the head, being left free to move towards the median line, under pressure of the right hand, still kept up steadily, glided downward into the pelvic brim. Holding the head in position at the brim with the left hand, and making firm pressure upon the uterus with the same arm, in order to render the membranes tense, I carried the index finger of my right

hand through the os uteri and tore through the membranes; the water discharged, the uterus contracted firmly upon the body of the fœtus, and fixed it in the normal position, and the trouble was permanently removed. The uterine contractions showing a disposition to inertia, I administered fifteen grains of quinia, which again roused them into activity, and at seven o'clock the second fœtus was expelled.

I then made a firm grasp upon the uterus, which soon was well contracted, but, as might be expected with twin placentæ, very large. The placenta not being at once expelled, I made an examination, and found it still firmly implanted upon the posterior wall of the uterus, just within the internal os, the lower margin being within easy reach of the finger. After continued expressive effort upon the uterus, the placenta was displaced and expelled beyond the vulva, although the uterus still remained large. Finding a firm band of membranes passing from the margin of the placenta into the vaginal cavity and resisting any reasonable traction effort to withdraw them, I followed them with the finger up into the uterus, when I found that instead of diminishing in bulk they increased into a large mass of membranes which again terminated in the margin of another placenta attached upon the posterior wall of the fundus. Continued manipulation and expression gradually displaced it, and it was expelled. Upon examination the two placentæ were found connected by a firm cohesion of a portion of the chorial surfaces, separable, however, easily by the finger.

The babies weighed eight pounds each, and were well developed, though not very vigorous.

An injection of hot water, carbolated, caused a firm contraction of the uterus, with no subsequent relaxation, and the puerperium was attended with no complication.

In the history of this case there are presented some points worthy of study, to which I will briefly call the attention of the members of the Society.

Not least among these is the value of this case as showing the influence of abdominal tension as a cause of albuminuria. That there is a predisposition in some patients to the production of renal disturbance from the condition of pregnancy alone, showing itself early,—before any possibility of pressure acting as a developing cause,—there is no doubt; and that in women who have already shown evidence of beginning Bright's disease, the occurrence of pregnancy becomes an aggravation, and is attended by a rapid increase of symptoms, is also well known; but it is none the less a fact that the acute Bright's disease of pregnancy, independent of the presence of an excessive abdominal tension, and consequent persistent and extreme pressure of the enlarged uterus posteriorly upon the abdominal vessels, is altogether exceptional. In other words, that it is a rare thing to have albuminuria, with its attendant anasarca and subsequent menacing of eclampsia, except in primiparæ, when the abdominal walls refuse to relax before the distending force brought for the first time to bear upon them, or exceptionally in multiparæ, where from some preternaturally rapid or extreme enlargement of the uterine tumor in the latter months of gestation, subjecting the abdominal walls to much more violent distention than in any previous pregnancy, the same result is brought about. Such cases are found in multiple pregnancies, and in excessive amniotic dropsy. In the patient under notice in the five previous pregnancies no renal symptoms had developed, even in the first; nor in the interval between this pregnancy and the preceding was there any deviation from a normal standard of health. Yet at about six months of gestation, when she began to suffer from a sense of great abdominal tension, the evidence of renal disturbance began to show itself, and became steadily more alarming, except when held in partial control by treatment, until the emptying of the uterus, after which it rapidly disappeared, the urine being at the end of twelve days entirely clear of albumen or casts.

In connection with this point it is worth while to call attention to the beneficial effects derived from the calcium benzoate, which could not be looked upon as a mere coincidence, dependent upon relief of pressure from uterine subsidence, nor upon the influence of other remedies, inasmuch as the renal symptoms abated steadily from the time of its administration, and began to increase again so soon as it was suspended. My experience with it in other cases has confirmed my belief that it will prove an efficient aid in controlling

the albuminuria of pregnancy, as well as a valuable remedy in Bright's disease from other sources. Mr. Shinn has produced a very beautiful crystalline salt of the calcium benzoate, consisting of exquisite translucent, colorless, acicular crystals, soluble in about the proportion of twenty grains to the fluidounce of water, and of this the dose I have adopted is in marked cases ten grains dissolved in a tablespoonful of fluid consisting of water with enough orange syrup to flavor it, to be administered every two or three hours during the day.

Another point is the value of external manipulation in establishing the conditions of pregnancy. Time does not permit me to enter fully into the consideration of this diagnostic means, by which now the well-instructed obstetrician can in almost every case make out distinctly not only the fact of pregnancy, but also the period approximatively of its advancement, the number of fœtuses, and the relations of the fœtus to the long axis of the uterus and to its transverse planes in the later months of gestation. So satisfactory has this become that I look upon it as a duty, wherever it is at all practicable, in every case over which I have the exclusive control, to make an external examination during the last three or four weeks of pregnancy, not only to avoid the disagreeable and serious possibility of finding at the last moment a case of spurious pregnancy, but also to detect in advance any malpresentation, or even a presentation of the breech, which would give ground for anxiety. In this case the value of abdominal manipulation was demonstrated in the diagnosis of the twin pregnancy, and afterwards both for diagnosis and correction of deviation in the transverse presentation of the second fœtus. This has become now so thoroughly recognized by first-class obstetric writers and teachers that no treatise on midwifery and no college course can be considered complete without giving full consideration to it as a necessary diagnostic measure, and full details of its methods of application.

Another point of interest to which attention may be called is the reconstruction of the cervix after the expulsion of the first fœtus, a condition which I have never seen before to the extent that was here present; giving protection to the second fœtus, and especially supporting the bag of waters, which, under the circumstances, involving a necessity for external version, was a fortunate exception.

Again, another peculiarity was found in the entire distinctness of implantation of the two placentæ, the one being low down near the internal os, the other at the fundus. This is the first case in which I have seen a separation of the two placentæ in my practice; nor have I ever seen an intercommunication between the vessels of the two placentæ. In every instance before I have found the usual conditions of a marginal union by connective tissue of various degrees, from a very slight, almost tangential union, to a condition in which the two placentæ were in form of two semicircles placed base to base; always with two distinct cords entering any portion of the respective placental mass, and sometimes entering so closely together upon the contiguous margins as to look at first like a single cord. An interesting feature of this case was the fact that the first placenta, although situated low down, and far below the portion of the uterus occupied by the remaining ovum, was not displaced by the uterine contraction which effected the second expulsion, and yet that, on the other hand, after the first placenta was expelled that portion of the uterus upon which it had been implanted did contract so firmly as to obliterate the open vessels of the uterus which had supplied it, so that no appreciable or troublesome hemorrhage showed itself in the interval of rest before the expulsion of the second placenta. Dr. Hodge, Sr., reports a similar case of placental anomaly.

There are some points in this case which might have been dwelt upon more at length, and more accurately developed in their obstetric relation; but the object of the report was simply to draw attention to them in their practical relation, and it would be an unwarrantable encroachment upon the time of the Society to do more.

1419 Walnut St., Philadelphia.

Bottle in the Rectum.—Dr. Rodenstein (*Annals of Anatomy and Surgery*, August, 1881) gives a case where a six-ounce medicine-bottle had been introduced into the rectum for the relief of hemorrhoids. The bottle escaped within the sphincter and gradually worked its way through the sigmoid flexure and transverse colon until it became fixed in the right iliac fossa at the cœcal pouch. The patient was relieved, under chloroform, by manipulation.

A NEW FORM OF GALVANO-CAUTERY BATTERY, AND A NEW INSTRUMENT FOR THE TREATMENT OF NASAL HYPERTROPHIES.

Read before the Philadelphia County Medical Society, June 8, 1881,

BY CARL SEILER, M.D.

BEFORE giving a description of the battery and the galvano-cautery knife, I will pass in short review those conditions of the nasal cavity in which galvano-cautery is applicable and presents advantages over other caustics which have heretofore been used for the same purposes that electricity now accomplishes. It is not my intention, however, to read an exhaustive dissertation on nasal catarrh and its different forms: I shall only point out those conditions of the disease in which I have found the use of the galvano-cautery knife to be the most satisfactory mode of treatment.

By far the greater number of cases of nasal catarrh which present themselves for treatment are those in which on examination of the nasal cavities we find portions of the mucous membrane to be hypertrophied, thereby producing partial or complete stenosis of the nasal passages according to the extent of the hypertrophies. These swellings have been proved to be true hypertrophies involving the epithelial layer, the submucous tissue, and the cavernous erectile tissue, as well as the mucous glands, by microscopical examination, and may be situated at the anterior or posterior portion of the turbinated bones, at the anterior or posterior portion of the septum, or, finally, in the vault of the pharynx, in the so-called pharyngeal tonsil. Besides giving rise to partial or complete stenosis, this hypertrophied condition of the mucous membrane gives rise to the secretion of large quantities of thick, tenacious mucus, which cannot be discharged through the obstructed nostrils, and consequently flows back into the pharynx, necessitating a constant hawking to dislodge it on the part of the patient.

Clinically these different phases of the disease have been divided into pharyngeal hypertrophy if situated in the vault of the pharynx, posterior hypertrophy if found at the posterior portion of the turbinated bones or the nasal septum, and, finally, anterior hypertrophies if they occur on the anterior portion of the turbinated bones or the septum. This latter class is by far the most frequently found, and is the one for the cure of which I am in the habit of employing the galvano-cautery.

There can be no doubt that these swellings of the mucous membrane, even when small and apparently insignificant, narrow the breathing-space in the nostrils and give rise to many of the annoying symptoms of nasal catarrh, and therefore I hold it as my opinion that they should be removed. Their very nature at once precludes the possibility of reducing them permanently by internal medication or local application of astringents, and it has been clearly demonstrated, to my mind at least, that nothing short of actual destruction of tissue is efficacious.

In treating anterior hypertrophies I am in the habit of making incisions across them with the galvano-cautery knife, at a cherry heat, deep enough to penetrate the mucous membrane and enter slightly the cavernous connective tissue, making only one or at the most two incisions at one sitting. It is necessary that the knife should be at a cherry heat, for if it be hotter considerable bleeding will follow the incision, and if it be cooler a great deal of unnecessary pain will follow the operation. The effect of such incisions is to produce bands of cicatricial tissue, which in contracting bind down the hypertrophic mucous membrane, and so relieve the stenosis. The unreliability of the galvano-cautery batteries now in the market, the inconvenience attending their use, and the costliness of the apparatus, have deterred many surgeons from employing this agent for minor operations within the cavities of the body where it is very desirable that there should be little if any bleeding. I myself, on account of these difficulties, was not able to use galvano-cautery until I constructed the battery which I have brought here this evening, out of material at hand. It is larger and heavier than need be, owing to the thickness and weight of the plates which I had and therefore used. The battery is one of carbon and zinc plates mounted on a board in such a manner as to give the greatest amount of quantity in the current. These plates are immersed in a liquid composed of sulphuric acid, bichromate of potassium, and water, contained in two large battery jars. The board to which the plates

are attached is swung between two levers, which are fastened to a cross-bar running the whole length of the box containing the jars, and revolving in slits cut into the end boards of the box. Outside of the box two long levers are fastened to the end of the cross-bar, the one carrying a weight sufficiently heavy to counterbalance the plates with the board upon which they are mounted, and the other having attached to it a treadle. When the battery is not in use, the plates are lifted out of the fluid by the counterweight and remain suspended above the jars. By placing one foot upon the treadle and making pressure upon it, the plates are immersed and the current is generated.

This mechanism, besides being very convenient and doing away with the necessity of having an assistant to immerse the plates and remove them from the fluid, places the amount of current to be used, and consequently the degree of heat in the knife, completely under the control of the operator; for the more pressure is exerted upon the treadle the deeper are the plates immersed and the more electricity is obtained. I am indebted to Mr. Griscome, of the Dynamo-Electric Company, for the idea and application of this mechanism. Another great advantage in this battery over all others is the fact that it can be used frequently without a necessity of renewing the fluid, for the jars are so large as to hold a large amount of fluid, so that it takes a long time before it becomes exhausted.

In using galvano-cautery for operations within narrow cavities, such as the larynx and nares, I found great difficulty in preventing the injury to other parts than those to be operated upon by the heat developed in the conducting wires of the knife, which usually are only covered with a thin layer of floss-silk. This readily burns off and leaves the wires bare, especially near the platinum loop, and, being of a black heat, may inflict very painful injuries to parts not intended to be burned. In order to obviate this difficulty, I searched for a substance with which the conducting wires could be insulated, and which would be at the same time a non-conductor of electricity and of heat, and found it in a substance called vulcanized fibre, manufactured in Wilmington, Delaware. The knife which I hand around has been in daily use for a number of weeks, and you see that the insulating sheath does not show the slightest trace of having been burned or injured by the heat, and when the current is passing making the platinum loop white hot, the sheath can be touched with the fingers without feeling more than warm.

1346 Spruce Street.

FATAL OTITIS.

Read before the Philadelphia County Medical Society, June 22, 1881,

BY G. C. HARLAN, M.D.,

Surgeon to the Eye and Ear Department of the Pennsylvania Hospital, and to the Wills Eye Hospital.

FOR the notes of the case which has recently called my attention to this subject I am indebted to my clinical assistant, Dr. C. H. MacIlwaine:

Sarah G., a delicate-looking child, 4 years of age, was brought to the dispensary of the Pennsylvania Hospital on the 6th of November, with the following history. She had measles two years ago, and there has been almost constant discharge from both ears since. Four months ago she was struck on the left ear, and since then there has been increased discharge from that ear, and pain, which has been constant and at times intense. For the last three days the pain has been much worse, keeping her awake at night. There has been no discharge from the right ear for some weeks. There is now no facial paralysis and no external swelling. The child is too nervous and restless for a thorough examination of the ear. Ordered ear-douche of boracic acid and warm water every two hours, and morphia at night.

November 11.—Mother noticed yesterday that the face was drawn to the right side, and there is now partial facial paralysis. Ether administered, and external meatus found filled with polypi, which were removed with forceps. Posterior and upper wall of meatus eroded, membrane destroyed, and ossicula exposed. Sol. argent. nit., gr. xl ad ℥j, applied on pledget of cotton.

November 13.—Rested well after the operation; has slept nicely for two nights, and, though the appetite is poor, she looks much better than before the operation. The facial paralysis is now complete; the left eye cannot be closed.

November 19, eight days after the operation.—Seen by Dr. MacIlwaine at her home. Intense headache and flushed face to-day. Temperature, 102°. Does not complain of pain in the ear, but is very restless.

November 23.—Has had constant headache and fever since the 19th; cannot be kept in bed; insists upon being held in her mother's

arms all the time, but is perfectly quiet if not disturbed.

November 26.—Seems in much the same condition. Great deal of headache, not located in any particular part; temperature high; quiet in mother's lap, and perfectly conscious.

November 28.—Slept fairly during the night, and seemed in about the same condition this morning, but became comatose, and in an hour afterwards died quietly.

Post-mortem, forty-eight hours after death, by Dr. MacIlwaine.—Membranes of cerebrum congested, but otherwise healthy. No sign of disease in upper surface of petrous bone. When cerebrum was removed, a bulging of the tentorium was noticed on the left side, and an abscess of the cerebellum, containing about half an ounce of pus and clotted blood, was discovered beneath it. The dura mater over the abscess seemed healthy, but the pia mater was partly destroyed and the remainder covered with lymph. The abscess was situated immediately over the entrance of the internal auditory meatus. The dura mater covering the lower aspect of the petrous bone was healthy, except at the entrance of the meatus, the edges of which were bared and bathed in greenish pus, which filled the meatus. The rest of the brain and its membranes were healthy. No other organ examined.

Examination of temporal bone.—Anterior wall of external meatus destroyed, except a narrow, jagged scale of bone; posterior portion bare and eroded; membrana tympani entirely destroyed; inner wall and floor of tympanum bare; mucous membrane about entrance of Eustachian tube and on roof much thickened; malleus and incus in place, but partially eroded; no trace of stapes; fenestræ rotunda and ovalis uncovered, and water injected into them passed out at once through internal auditory meatus; the floor of the tympanum was as thin as tissue-paper, and there was a large perforation through the anterior edge of the jugular fossa; the portion of the fossa corresponding to the floor of the tympanum was bare and rough; the vein was sound and apparently healthy; on the inner surface of the bone the dura mater was everywhere perfectly healthy, except at the mouth of the internal auditory meatus; around the margin of this opening there was a free, loose edge of dura mater, raised by the pus that filled the meatus. The facial and auditory nerves, embedded in this pus, were in a sloughing condition; on removing them the walls of the meatus were found entirely bare throughout their whole extent, but there was no caries. The foramina at the bottom of the meatus were of their normal size. The passage of water from the labyrinth to the meatus would seem to have been due to the destruction of the lining membranes of the bone. The thick greenish pus which filled the interior auditory meatus must have been formed there by the destructive inflammation of the dura mater lining it. This canal being a part of the intracranial cavity, there was no further obstruction to the progress of the disease to the cerebellum.

The unprotected condition of the jugular vein, which really formed a part of the floor of the tympanum, not even covered by mucous membrane, illustrates the necessity for care in the use of instruments in the middle ear; and the fact that fluids poured into the porches of the ear may, even without the presence of caries, pass directly to the brain, has practical interest.

Four other cases of death from disease of the ear have occurred in my practice, including one in the Pennsylvania Hospital while I was resident surgeon.

Case II.—The notes of this case have, unfortunately, been lost, and so long a time has passed that my memory can recall only its general outlines. The patient presented himself with complete paralysis of the facial nerve, which he stated was the result of a blow upon the side of the head received the day before. What appeared to be a polypus was discovered in the external auditory meatus of the same side, but it proved, on removal, to be the end of a broken knife-blade covered with granulations which had sprung up around it. Its point was embedded in the bone. The patient then stated that he had been assaulted by some boys about a year before, who had inflicted several wounds with penknives, one of them in the ear; but that he had suffered only a slight discharge and was not aware of the presence of a foreign body. There was extensive caries of the meatus and tympanum, and death resulted in a few weeks from direct extension of the disease to the brain.

The three other cases have already been reported, but may be briefly referred to. The specimen I now present is the temporal bone of a patient whose case was reported in the *Philadelphia Medical Times* for November 16, 1872.

Case III.—She was a delicate girl, 22 years of age, whose mother had died of phthisis. She had been subject to occasional discharge from the ear since early childhood, and death resulted from an abscess of the brain following upon a violent attack of otitis, which involved the tympanum, mastoid, antrum, and external meatus. The abscess was as large as a hen's egg, and rested on the upper surface

of the petrous bone, from which it was separated by the membranes and a thick layer of lymph. There was a small opening through the membranes. An interesting point in the history of the case is that the diagnosis of cerebral disease was confirmed, some time before death, by the ophthalmoscope, which revealed marked choked disks in both eyes, though there was no noticeable diminution of vision. Nearly half of the roof of the tympanum from the entrance of the Eustachian tube backward is destroyed, and the upper part of the posterior wall is gone, the tympanum and mastoid antrum forming one continuous cavity. Nothing remains of the roof of the mastoid antrum but a thin bony scale with large perforations. The outer part of the posterior wall of the external meatus and the bone around it are honeycombed, and contain sinuses leading to the mastoid cell. Notwithstanding the extensive destruction of the walls of the tympanum, the portio dura has escaped. There was no facial paralysis, though the nerve was exposed at several points by openings in the aqueduct of Fallopius. The membrane was destroyed, and there was a large polypus just within the tympanum. The development of the temporal bone is very deficient for an adult, and the mastoid process is little more than rudimentary. What there is of mastoid is sclerosed, and shows only a trace of the vertical cells,—a not uncommon result of chronic inflammation of the bone.

The two other cases were of malignant disease.

Case IV.—The specimen presented is from a woman 55 years of age, who applied for relief from a swelling behind the right ear, nearly the size and much the shape of half a hen's egg. It had so much the appearance of an abscess with very thick tense walls that two free incisions had been made in it by a surgeon. These incisions had gaped widely, and fungous granulations were springing from them. They soon assumed the character of foul-looking, sloughing ulcers, with an offensive, sanious discharge, and rapidly increasing in depth. An opening, through which the discharge flowed profusely, was formed into the external meatus and extended until the auricle was almost dissected off. As the disease progressed inward, the portio dura was involved, and the right side of the face was completely paralyzed. After several months of intense suffering, death resulted from direct extension of the disease to the brain. Nearly the whole of the mastoid portion and a part of the petrous and squamous portions of the temporal bone, the wall of the external meatus, and the angle of the parietal bone have been destroyed. The tympanum has been laid open by the destruction of its membrane and a part of its roof. When we consider the great extent and rapid progress of the disease and the close proximity of the lateral sinus, internal jugular, and carotid, it seems singular that there was no considerable hemorrhage. The carotid foramen is to a great extent, and the jugular foramen almost completely, obstructed by a bony deposit.*

Case V. is that of a little girl, 3 years of age, a patient in the Eye and Ear Department of the Children's Hospital. A year before coming under observation she had scarlet fever, and had not been in good health since. Three months before, she became restless and seemed in pain; and two months before, a slight discharge of blood from the meatus was observed for the first time. There was a fluctuating swelling beneath and behind the left auricle, and in the external meatus a thick, purulent discharge and a firm, rounded polypus the size of a pea, or larger. The facial nerve was paralyzed. The polypus was removed and an incision made into the external swelling. From the latter there was a copious discharge of offensive pus. In about two weeks the wound gaped and a fungous growth appeared in it. The polypus rapidly reformed, but became strangulated by constriction in the meatus and sloughed. The child died in about eight weeks after she was brought to the hospital. No post-mortem examination was permitted beyond the removal of the tumor. Extensive erosion of the temporal bone could be felt by the finger introduced into the wound. The extension of the disease inward was fully proved before death by paralysis of the seventh, third, and fifth nerves. Microscopical examination showed the growth to be a round-celled sarcoma.†

Though malignant disease of the middle ear is very rare,—so rare that it is not even mentioned in some of the standard text-books on aural surgery,—it is well to

* Reported in Transactions of Pathological Society of Philadelphia, vol. iv.

† Philadelphia Medical Times, December 13, 1873.

bear in mind the possibility that an aural polypus or a mastoid swelling may have this character, and that active interference may only hasten the fatal result.

Disease of the ear may result in death by means of intracranial abscess, meningitis, hemorrhage from eroded vessels, thrombosis of the lateral sinus, or purulent infection with metastatic abscess in distant organs, with or without accompanying lesions of the brain. These are not merely theoretical possibilities, but matters of history, with abundant records in medical literature to substantiate them all. The most frequent of these fatal lesions is intracranial abscess; and Lebert estimates that about one-fourth of all cases of abscess of the brain have their origin in caries of the petrous portion of the temporal bone.

Before attempting to trace the various paths that the disease may follow to its fatal termination, it may be well to recall some of the more important anatomical relations of the ear. The upper surface of the petrous bone is in relation with the cerebrum, and its posterior surface and the mastoid process with the cerebellum and the petrosal and lateral sinuses; the dura mater in both cases performing the part of periosteum. On its anterior inferior surface, which forms a part of the base of the skull, are found the carotid canal and jugular fossa. In the upper surface of the petrous bone are the upper walls of the tympanum, the mastoid antrum, and the labyrinth; on its posterior surface is the posterior wall of the labyrinth, and on its inferior surface the floor of the tympanum and of the labyrinth, while the inner wall of the mastoid cells forms the lateral sulcus. On all these surfaces there is more or less direct communication between the ear and the brain through foramina for the transmission of vessels and nerves. When disease is communicated directly from the roof of the tympanum or mastoid antrum, the cerebrum suffers; when it extends from the labyrinth or mastoid cells, including the posterior wall of the antrum, the cerebellum is, as a rule, involved; while the carotid artery and jugular vein are endangered by caries of the anterior wall and floor of the tympanum.

Whatever course the disease may eventually take, its origin is usually in the tympanum, from which it may extend in various directions. The most frequent is through the roof of the tympanum to the middle lobe of the cerebrum which rests upon it. The tegmen tympani varies much in health, and is sometimes as thin as parchment, or even deficient in places, leaving the mucous membrane of the drum in contact with the dura mater. In the greater number of post-mortem examinations made after death resulting from otitis, the roof of the tympanum has been found carious. In some cases meningitis has been the immediate cause of death; but the most frequent cerebral lesion is abscess. The abscess may be in direct contact with the carious bone, as in Case III., but is frequently—according to some authorities, in the majority of cases—at some distance from the drum, and with sound brain-substance intervening between them. The pathology of the latter class of cases is somewhat obscure. The disease is generally supposed to be conveyed through the blood-vessels, probably by emboli, though the absence of symptoms of the condition known as pyæmia, and the fact that the abscess is always found on the same side of the brain as the otitis, would seem to show that it is not exactly of the nature of typical metastatic abscess. As a proof of unsettled pathology, it may be mentioned that *bacteria* have been called upon to do duty in explanation. McBride and Bruce and Binswanger* believe that cerebral abscess resulting from disease of the temporal bone, but separated from it by healthy brain-substance, may be caused by infectious micro-organisms passing into the circulatory system from the purulent points, or transported along the perivascular connective tissue. As the roof of the horizontal mastoid cell, or mastoid antrum, is continuous with that of the tympanum, and the partition of delicate cancellated bone between them is easily broken down, they are likely to constitute practically one cavity in cases of long-standing disease. The propagation of disease from the roof of this cavity to the cerebrum is well illustrated by Case III.

Acute inflammation of the tympanum also sometimes extends to the brain. Toynbee reports a case of cerebral abscess without caries of the bone, occurring in two weeks from the commencement of an otitis media; and other somewhat similar cases are on record.

Another direction that the disease has

* Journal of Anatomy and Physiology, vol. xiv. p. 360.

taken in quite a number of reported cases is through the labyrinth and internal auditory meatus to the cerebellum, as in Case I. The destruction of the membrane of the fenestra rotunda or fenestra ovalis at once opens a free passage for pus from the tympanum to the labyrinth. In addition to this there is an anastomosis between the blood-vessels of the tympanum and those of the labyrinth. When the purulent process is once established in the internal ear there is no other obstruction to its progress towards the brain than the thin cribriform plate at the bottom of the internal auditory meatus, which, as we have seen, may be readily passed. Indeed, Hyrtl has stated that "it is not impossible that the perilymph of the vestibule is cerebro-spinal fluid." The middle and the internal ear have also been found to communicate through a perforation of the promontory by caries. Another possible channel of communication between the tympanum and the internal auditory meatus is along the course of the portio dura in the aqueduct of Fallopius, though I am not aware that any case of the kind has as yet been reported.

Though any other than a fatal result of extensive necrosis of the labyrinth must of course be extremely rare, several recorded cases prove that it is not impossible.* One was reported in the *Philadelphia Medical Times* for June 15, 1871, by Dr. W. W. Keen, to whom I am indebted for the opportunity to show this very interesting specimen, which was removed through the external meatus. It consists of the "entire petrous portion of the temporal bone, much eroded, but still showing the auditory meatus and the walls of the three semicircular canals. Of the carotid canal no distinct trace could be found, but a groove on the inferior surface seemed to indicate where it had been." The patient, a child five years old, lived to grow fat and hearty afterwards, though what was left of life—with hearing, sight, taste, and smell entirely lost—was hardly worth the preserving. The subsequent condition has been more favorable in some of the other cases.

A frequent course of the disease in its fatal progress towards the brain is by way of the mastoid cells. Mastoid suppuration may prove fatal through basilar meningitis, inflammation of the cerebellum, with or without abscess, or hemorrhage from or thrombosis of the lateral sinus. A glance at the relations of the mastoid process to the cerebellum and the lateral sinus can leave no doubt of the danger of a destructive inflammation of that bone or of a collection of pus in its cells. The operation for giving exit to such collections by perforating the bone has been successfully performed in a number of cases, and may now be considered as one of the established operations of surgery. That extensive mastoid disease may, however, sometimes spontaneously end in recovery in young subjects is shown by the not very unfrequent exfoliation of large portions of the bone in children.

For the opportunity to illustrate, by means of two specimens, the extension of disease from the mastoid cells to the lateral sinus I am indebted to the kindness of Dr. W. W. Keen and Dr. Morris Longstreth. The case from which this specimen was taken is reported in vol. viii. of the Transactions of the Philadelphia Pathological Society. There is a large carious opening from the mastoid cells directly into the lateral sinus. The sinus is filled with a gangrenous thrombus extending to the torcular Herophili. The superior petrosal sinus is also filled by a thrombus. The septum between the tympanum and the mastoid antrum is destroyed, but the other walls of the tympanum are intact, and the ossicula are in place. There was localized softening of the cerebellum. The mastoid was trephined.

The other specimen is from the museum of the Pennsylvania Hospital, and has also been presented to the Pathological Society (vol. x.). The patient (S. G., 49 years of age) had had purulent aural catarrh for a month before death, following upon an attack of erysipelas of the head and face, and presented cerebral symptoms towards the close of her life. The wall of the lateral sulcus is destroyed, and the partitions of the mastoid cells, both vertical and horizontal, are broken down, so that the mastoid space and the sulcus form a single unpartitioned, ragged cavity, which was lined with dense granulations. There is a large carious opening between this cavity and the external meatus. The squamous portion of the temporal bone is diseased, and is nearly separated from the rest through the petro-squamous suture. The

* See Wien. Allg. Zeit., Nos. 41, 43, 45, 1864, and Roosa's edition of Tröltsch.

auditory ring is entirely separated from its bony connections and is held only by the soft parts. The roof of the tympanum was removed for examination of the cavity, which was found much changed: its lining membrane was covered with granulations, and it contained thickened pus and shreds of tissue. The ossicles were in place, but partly denuded, and were bathed in pus. The Eustachian tube was also filled with thickened pus. The lateral sinus was filled with a black clot, and there were purulent basilar meningitis and inflammation of the anterior and under surfaces of the cerebellum.

Still another fatal course that tympanic disease may take is by involving the carotid artery or jugular vein. The bone separating the tympanum from these vessels is sometimes extremely thin. That forming the floor of the tympanum and the jugular fossa has been found deficient, from defective development, having openings where the mucous membrane of the drum was in contact with the vein. A number of cases are recorded in which death resulted from injury to these vessels. In several instances fatal hemorrhage from the artery has been prevented by ligation of the common carotid.

Direct extension of the disease from the middle ear to neighboring vital parts is not the only danger that threatens the life of a patient with purulent aural catarrh. A number of cases are on record in which death has resulted from pyæmia with metastatic abscesses in distant organs. This is by no means surprising when we consider that the temporal bone contains large cavities which have direct venous communication with the intracranial sinuses and which are frequently found filled with pus. The bone itself has also free vascular communication with the dura mater on one hand and the mucous membrane of the middle ear on the other; and it is a well-established fact that disease may extend from the ear to distant parts, as well as to the brain, even without the intervention of caries. For an illustration of this fact I am indebted to Dr. Burnett. This specimen is from a patient whose case is reported in vol. vii. of the Transactions of the Pathological Society of Philadelphia. There was a copious purulent discharge from the right ear, with intense pain in the ear, mastoid region, and right side of the head. Dr. Burnett trephined the mastoid with great temporary relief to the patient, who was thought to be convalescent, but who died sixteen days after the operation. The brain and the intracranial sinuses were healthy, but metastatic abscesses were found in the liver and lungs. The membrane was gone, and the tympanum and mastoid cells were filled with a cheesy mass of purulent débris. There was no caries, but the bone presents evidences of disease in hyperostosis of the outer wall of the mastoid cells and minute perforations of the inner wall.

The specimens that you have seen illustrate the extension of disease from the tympanum through its roof, through the internal ear, and through the mastoid to the brain, and through the circulation to distant organs. I have not been able to obtain one showing the progress of disease through the floor of the drum; but in Case I. the conditions of a fatal issue by this direction existed, in the extreme thinning and partial destruction of this part of the bone; and it could scarcely have been long delayed if it had not been anticipated by the deeper lesion. These specimens speak for themselves with the eloquence of evident facts, and do not need extended comment.

Von Tröltsch, after describing to his class the anatomical relations of the middle ear, exclaimed, "Do you know a small cavity in the human body which borders in a similar manner on so many important organs, and in which we should, therefore, so anxiously regard purulent processes and their common consequences?" It must be freely and thankfully admitted that the appreciation by the profession at large of the grave importance of these processes has of late years wonderfully advanced; but I may be excused for expressing the conviction that they are, even yet, far from being generally accorded the anxious attention that they deserve. Perhaps the prevalence of polypi in a given number of cases of otorrhœa may be considered as a fair indication of the degree and kind of care that the patients have received; and I have noticed a decided diminution in the proportionate number of these growths occurring in both hospital and private practice in the last ten years. It is, however, hardly an exaggeration to say that such a thing as an aural polypus should be almost unknown in a civilized community. It is not many years since, even among the

shining lights of the profession, the favorite prescription for a chronic purulent otitis was to let it alone, enforced, perhaps, by the general dictum that it was not well to meddle with the ear, or accompanied by the comforting assurance that the patient, if a child, would "grow out of it." It must be confessed that this rather barbarous expression still sometimes, though happily not often, crops out in the history of a case; and it is true that the patient may grow out of it, so far as the continuance of the loathsome discharge and the danger to life are concerned, and, at the same time, grow out of his hearing. But, on the other hand, it should never be forgotten that he may grow into it more deeply and dangerously every year, until life is sacrificed at last to the unopposed progress of a disease which in its earlier stages would almost certainly have yielded to careful and skilful treatment.

NOTE ON SCHUYLKILL WATER.

Read before the Philadelphia County Medical Society, June 22, 1881,

BY HENRY LEFFMANN, M.D.

IT is my purpose to take only a few minutes to give some results, or rather conclusions, which have been derived from recent analyses of our water-supply. Very little is heard about the hygienic relations of Schuylkill water, probably because public opinion has long since settled to the conclusion that it is a good water. Nevertheless, as visitors sometimes complain of it, and as newspapers in their flings at the water department not infrequently condemn the quality as well as the quantity of the supply, I have ventured to take up the Society's time long enough to say that examination made at various times during the winter and spring have shown that the water is of fair quality and cannot be regarded as an active cause of disease in our city. It is an insipid water, lacking the pleasant taste and sparkling character of spring water, especially of the so-called hard waters, and this lack is often taken as evidence of impurity. During the periods of freshet it becomes quite turbid from the suspension of particles mostly silicious; but such suspended matter rarely exceeds a grain or two to the gallon, and the individual particles are too minute to cause any irritation. In the turbid water several species of harmless animalcula can usually be detected. In making any brief statement of the composition of a water we are embarrassed by the fact that the modern methods of water analysis are very strictly technical: they give us not the impurities themselves, but the amount of certain indications of impurity. Without stopping to explain the mere chemical phase of the question, I will simply give a comparison of a recent analysis of Schuylkill water with that of two samples of London water analyzed by the same method and considered excellent waters:

	Schuylkill.	Kent Company, London.	Chelsea, London.
Chlorine	0.53	1.2	0.51
Ammonia, from organic matter	0.0028	0.0022	0.0035
Total solids	7.00	34.00	17.64

All the figures are grains to the imperial gallon.

The Society of Public Analysts of England has recently proposed a system by which each factor in the composition shall be valued by an arbitrary number, and all the numbers being added will give us a figure representing the standard of the water. In good waters this sum will not exceed 35. Schuylkill water varies from 17 to 23, so that it comes decidedly below the limit. In regard to Delaware water I may remark that, so far as I have examined it, it is not as good as the Schuylkill water. The amount of organic matter is higher, and the microscopic examination shows forms of life which are frequent in decomposing materials.

TRANSLATIONS.

PURPURA HÆMORRHAGICA AS A NEUROSIS.—The nervous origin of certain cutaneous affections, says Dr. H. Leloir in *Le Progrès Médical*, is a question of great interest at the present time. Recent observations tend to confirm the opinion of Drs. Stieldorf, Wagner, Henoch, Couty, and others as to the nervous origin of some cases of purpura. Rigal and Cornil (*Soc. Méd. des Hôp.*, Fév. et Mars, 1879), in discussing a case of acute purpura hæmorrhagica of which they made an autopsy, propose the following conclusions: 1. Severe purpura hæmorrhagica is a group of symptoms constituted essentially by hemorrhages in the skin and mucous mem-

branes and by progressive weakness resulting in nervous exhaustion not always commensurate with the amount of hemorrhage. 2. Whatever are the other morbid conditions which may have been concerned in the production of a given case of purpura hæmorrhagica, it is necessary to include some trouble with the vascular innervation if we are to understand the causation of the hemorrhages. This nervous disturbance may be either excitation of the sympathetics or diminution in the action of the vaso-motor centres. 3. The alterations in the blood and the lesions of the vascular walls appear to be variable and inconstant. While admitting their importance, they appear insufficient to produce purpura hæmorrhagica without some nervous perturbation.

Mackenzie (*Medical Times and Gazette*, March, 1877), referring to a case of purpura occurring in a young girl, and disappearing under the influence of treatment, only to reappear anew at the menstrual period, and giving rise to fatal symptoms, seems to think the affection due to an intracranial lesion. He does not, however, in the opinion of Dr. Leloir, bring forward sufficient proof to sustain this view.

Maiocchi (*Lo Sperimentale*, February, 1877) thinks that purpura rheumatica belongs neither to a diathesis nor to a dyscrasia nor to an infection. He makes it out an affection of the vaso-motor system. Cavalier (*Bull. Gén. de Thérap.*, 1879) reports a case of purpura hæmorrhagica alternating with paralytic symptoms. Finally, Shand (*Lancet*, July, 1879) has obtained good results in purpura hæmorrhagica by the use of electricity.

The attention of surgeons has long been drawn to certain scarlatiniform eruptions showing themselves after wounds and injuries. Authors are, however, far from being in accord in their views on the nature of these eruptions.

Stirling (*St. George's Hospital Reports*, vol. x., 1879), in an important and judicious memoir based on thirty-nine personal observations, and after discussing all the cases of the kind which have been reported, concludes that these eruptions are sometimes those of true scarlatina, while at other times they are simply scarlatiniform and non-infectious in character, resembling in pathogenesis certain erythemata, herpes, and certain papular eruptions which show themselves after injuries. He classes them as vaso-motor eruptions, regarding them as similar to the rashes which often occur in recently-parturient women. Dr. Kidd (*Dublin Journal of Medical Science*, April, 1880), who has studied these last, calls them uterine erythemata or "roseola uterina." This rash shows itself without febrile disturbance or general symptoms on the third to the fifth day after confinement, and exercises no unfavorable influence on the course of the confinement.

Frilet ("Contribution à l'Étude des Manifestations herpétiques dans leurs Rapports avec le Traumatisme") asserts the fact of the occurrence of herpes after traumatism, and says that, although in some cases it may be accounted for by reflex action, yet it is usually the expression of a general cause exercising its influence on the whole organism, which the injury sets in action. Finally, Auspitz, in his new classification, has the class "angioneurotics," which includes peliosis rheumatica.

TREATMENT OF INTERMITTENT FEVER BY SULPHATE OF QUINIA BASED ON THE EPOCH OF ITS MAXIMUM ACTION—PREVENTION OF RELAPSE BY QUINOIDINE.—In an interesting paper on this subject, published in the *Bull. Gén. de Thérap.* (1881, p. 347), Dr. Jules Augé, after speaking of the usual methods of giving quinia in use at present, suggests some modifications, as follows. He prefers to give the sulphate of quinia in powder covered with the usual bread-wafer, as being most efficient. In the treatment of the quotidian type of fever in adults, Augé gives eight grains of the sulphate of quinia in two equal doses, the first given four hours and the second two hours before the expected attack. Immediately after taking the medicine the patient swallows a bowl of soup or broth. The same dose is given daily for four days. In children from three to ten years of age, three- to four-grain doses are given in the same way. To infants, the syrup of quinia, composed as follows, is given:

℞ Quiniæ sulph., gr. xvj;
Acid. sulphuric. dil., q. s.
Dissolve, and add
Syrupi acid. tartaric., ℥viiss;
Syrupi simpl., ℥x.

The dose is two teaspoonfuls (*i.e.*, gr. ij) four hours before the attack, and two more two hours before it. Then the breast or bottle, or a little soup, is given, according to the infant's usual diet.

In tertian ague four grains of quinine are to be given four hours before the attack, and the same quantity two hours before it, with the soup as usual after each dose. On the day of intermission four grains are taken in the morning, and four more in the evening. Similar doses are given in the same way through two or three attacks of fever and apyrexia. Commonly, this course of treatment lasts four to six consecutive days. Subsequently quinoidine is administered. In children the plan followed is similar, but the syrup of quinia is used in appropriate quantities.

In quartan ague Dr. Augé gives eight to twelve grains on the day of the fever, divided into two doses and taken as above. On each day of apyrexia he gives four to five grains morning and evening, and this is kept up during two complete series of fever and apyrexia. Then, during the two series following, the quinine is replaced by a few teaspoonfuls of wine of quinoidine. It is then employed once more during a couple of series, and is subsequently permanently replaced by the quinoidine continued during a fortnight or more.

This method of treatment is particularly efficacious in those forms of malaria which are apt to occur in late autumn or winter, and which are so apt to be accompanied by engorgement of the abdominal viscera, chiefly of the spleen, and with malarial cachexia.

When quinine cannot be used on account of its cost, Augé strongly urges the employment of quinoidine, which, after a long series of experiments, has been found a most efficient substitute for quinine. The dose is larger, but it is soluble in water, and therefore more easily administered. It may be given in powder, pills, dragées, tincture, or syrup. For infants at the breast, the dose is one-sixth grain, and it runs up to eight to sixteen or twenty grains for adults. The method of administration recommended by Dr. Augé is that above given for quinine.

To prevent relapses, Dr. Augé gives the wine of quinoidine until the spleen is reduced to its normal condition. His conclusions are, essentially, that the maximum action of quinine is shown two to four hours after its ingestion; that it should never be taken fasting; that the most soluble forms of the drug are to be preferred; that wine of quinoidine should follow quinine to prevent relapses.

The Etiology of Gangrene of the Mouth (Noma).—Dr. Krasine (*La France Médicale*, 1881, p. 657; from *Vratchebniya Vaidomosti*) gives the case of two persons—a mother and daughter, aged respectively 48 and 8 years—who, following the endurance of great hardship, were attacked with gangrene of the face. Examined in the hospital two weeks after the beginning of the disease, for which neither treatment nor attention had been previously obtained, the greater part of the right cheek was found in both cases to have been destroyed by gangrene. The patients died after a fortnight's stay in the hospital, the disease having run a course of a month, which is rare in fatal cases. Krasine, in reporting the cases, discusses the pathogeny of noma in general. It is rarely found in adults,—usually in children of ten to twelve years, following eruptive or intermittent fevers. Its occurrence is favored by bad alimentation, damp dwellings, and the abuse of mercury (?—Ed.). It is more frequent among girls than among boys.

Noma generally begins by the appearance of a patch of induration situated on the mucous surface of the cheek near the labial commissure, and which is quickly surrounded by minute phlyctenulæ. The neighboring parts swell, the patch becomes black, it spreads on the surface and deeply, the soft tissues become involved, and even the bone is affected. After the removal of the sphacelated portions a hideous hole remains in the side of the cheek. Death occurs in seventy cases out of one hundred. In case of cure, extreme disfigurement, with adherent cicatrices, is apt to ensue.

This disease has sometimes been considered to originate in some disorder of the nervous system, particularly the vasomotors of the face. Krasine, however, is inclined to think that it is due to a cutting off of the blood-supply in an anæmic and broken-down person by the exercise of pressure. This pressure may in some cases be the result of lying on one side or the other during a prolonged illness, and is thus nothing more than a gangrene from decubitus.

Noma is generally limited to one side of the face: it rarely attacks the other side. Above, it may reach to the free border of the under eyelid and to the ear. It rarely

passes beyond the border of the lower jaw. The tongue and the eye of the affected side remain untouched. Noma attacks children because, in Krasine's opinion, the amount of blood in the body is relatively smaller than in adults, nutrition-changes are active, and anæmia is quickly produced and has grave consequences. Why the disease should attack little girls by preference is as yet inexplicable.

The treatment of noma has hitherto been by means of local remedies, caustics, the cautery, etc. Krasine, however, speaking from his point of view of the origin of the disease, urges improved nutrition, tonics, stimulants, etc., with simple antiseptic dressing.

A Case of Universal Xanthelasma Planum et Tuberosum.—At a recent meeting of one of the German medical societies (*Deutsche Med. Wochens.*, 1881, No. 23) Dr. Korach described the case of a woman of 25 suffering with chronic icterus, the result of total closure of the ductus choledochus of some standing. In addition to the typical patches of xanthelasma on the eyelids, the affection existed in the various parts of the body generally. While the extensor surfaces of the upper and lower extremities, as well as the nates, showed chiefly the tuberose form, the flexor surfaces displayed the flat or macular variety. In the palm of the hand and the volar surface of the fingers and thumb the patches of xanthelasma followed in confluent form the lines and furrows of the skin. Sometimes the patches coalesced into larger areas and were raised above the surface. Certain parts—as the nates, and the extensor surfaces of the knee and elbow—were thickly strewn with sago- to pepper-corn-sized xanthelasma tubercles. The color of the lesions was the typical dull yellow of xanthelasma.

Microscopic examination of the lesions showed hypertrophy of the connective tissue-cells of the corium, with an extraordinary finely-granular (fatty) degeneration or infiltration of the connective-tissue cells. There were no signs of hypertrophy or hyperplasia of the sebaceous glands.

Korach suggested that some cases resembling xanthelasma in external appearance are, in fact, commingled milium grains, as in the case of the affection published by Geber and Simon under the name xanthelasma, and which showed hypertrophy of the sebaceous glands. We have the choice either to give the name "xanthelasma" a purely symptomatic significance, including under this head all those xanthoma formations on the eyelids which chance to be of the same form, color, and general arrangement, or to take an anatomical stand-point, and only to designate as xanthelasma those cases where the lesions, in addition to presenting the typical external appearance, show the microscopic structure of fibroma lipomatodes. Korach urged the latter view, asserting that in all cases heretofore described, that of Simon and Geber excepted, the anatomical appearances were as above described. The xanthelasma in Korach's case was quite acute, having developed within a few weeks. It was accompanied by icterus with much pruritus of the skin, which lasted a month. After a year's stay in the hospital, the flow of bile into the intestine was finally established, and the icterus disappeared, the xanthelasma also fading away to a very considerable extent.

A Singular Case of Syphilis.—At a recent meeting of one of the French medical societies (*Bull. Gén. de Thérap.*, 1881, p. 378), M. Polaillon gave an account of a girl, 12 years of age, who had entered the hospital for a small ulcer on the sole of the foot. Five months and a half previously she had bought a new pair of shoes, and a projecting nail in one of them wounded the sole of the foot. A little later a lump appeared at this point, which soon broke into a deep ulcer. Later, others appeared in the neighborhood, and, joining, formed a phagedænic (?—Ed.) sore with hard, elevated edges, slightly excavated and painless, the girl continuing to go about on her feet. A month and a half after the appearance of the indurated lump the patient fell and struck the tibia. This resulted in the formation of a swelling in the bone, and finally in exostosis. There was no falling of the hair, generalized eruption, sores in the mouth, nor nocturnal pains. The patient was put to bed and the sores dressed with carbolic acid dressing, but no improvement took place. Iodide of potassium was then given, and in five or six weeks the patient was well. The absence of a history made the ulcer rather a difficult one to diagnosticate. Of course, Polaillon does not insinuate that the ulcer was anything more than a late lesion of some forgotten syphilis.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, AUGUST 27, 1881.

EDITORIAL.

WASTED OPPORTUNITIES.

TO the thoughtful mind, the waste of clinical opportunity observable in our large medical centres, and in Philadelphia perhaps no less than elsewhere, appears deplorable and discreditable. While the question of misplaced medical charity and of excessive gratuitous treatment has aroused no little attention, yet it must be remembered that the medical profession at large may be losers in more ways than through the pocket. The scores of young professional men who seize eagerly on each vacant position occurring in dispensaries and out-patient departments of hospitals too often forget that in entering upon the privileges of these posts they at the same time tacitly assume the obligation to themselves as well as to their profession to make the best possible use of the chances offered for recording unusual cases, experimenting with new remedies, or even the collection of statistics. That this may be done is shown by the fact that some of the most creditable papers appearing in our journals or read before our societies are from the few younger men whose only opportunity for clinical research is found in out-patient or dispensary practice. In fact, books reflecting honor on the writers and on the profession of this city have within recent years been written by those who have had no beds in hospitals nor even the large clinical advantages enjoyed by the considerable number of young hospital and dispensary doctors whose chief ambition at times appears to be to get through the day's work and have it over with, and who are content to prescribe "house-mixtures" and "Pill 3" or "4" as the quickest way of disposing of cases, while numerous problems to be solved are lying ready to hand and calling for study and investigation.

Bacon, in an oft-quoted aphorism, says that "every man is to be held a debtor to his profession; from the which as men of course do seek countenance and profit, so ought they of duty to endeavor themselves, by way of amends, to be a help and ornament thereunto." Would that this wholesome sentiment could be graven on the walls of every hospital and clinic!

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A CONVERSATIONAL meeting was held at the Hall of the College of Physicians, Philadelphia, March 9, 1881, Dr. Albert H. Smith, President of the Society, in the chair.

Dr. Albert H. Smith read a paper entitled "Clinical Notes of a Case of Twin Pregnancy" (see page 744), and Dr. Wm. S. Little read one on "Symptoms (Reflex) in and about the Eye, due to some Affections of the Uterus or its Appendages" (see page 581). A vote of thanks was tendered by the Society to Drs. Smith and Little for their interesting communications.

DISCUSSION UPON DR. SMITH'S PAPER.

Dr. O'Hara said that in two cases of albuminuria of pregnancy this symptom improved under the use of the benzoate of calcium, but in a case of scarlatinal Bright's disease he had not seen any benefit. As regards the causation of puerperal albuminuria, he thought that if the condition were solely due to the pressure of the enlarged uterus upon the kidneys the albuminuria would continue until the termination of the pregnancy, and would not admit of relief by remedies. He inquired whether the lecturer believed that a diagnosis of twin pregnancy can always be made prior to delivery. Dr. O'Hara reminded the lecturer of a case in which twin pregnancy was suspected by him upon examination, but which proved to be only a case of single ovum. The speaker did not think that a twin pregnancy would be more likely to be associated with albuminuria than an equally large gravid uterus containing a single fœtus.

Dr. Horner, of Virginia, being invited to take part in the debate, thanked the lecturer for his interesting paper.

Dr. W. R. D. Blackwood inquired whether the lecturer had had any experience with the remedy in any other cases than in pregnancy. Differing from the last speaker, he believed a twin pregnancy more liable to be complicated with albuminuria than a single pregnancy, because in the latter pressure from the gravid uterus is more upon one kidney, generally the right, while in the twin pregnancy the pressure is made upon both kidneys.

Dr. Henry H. Smith asked in regard to the utility of the lime in the combination. Benzoic acid is generally known to be very useful in many forms of renal disease, and especially in catarrh of the bladder. Dr. Bird, in his work on the urine, refers to the value of this agent, and especially mentions enlarged prostate with irritable bladder. He, therefore, inquired whether it was the benzoic acid or the lime that was effective in the cases reported by the lecturer. An incidental advantage in giving the benzoic acid alone is that it can be given in solution, whereas the benzoate of calcium must be given in powder.

Dr. Albert H. Smith said that he had no doubt that the lime was of service. For a long time he had treated chronic Bright's disease with various forms of lime, especially lime-water. with good results, giving it in large doses, especially in anæmic cases, with iron and cod-liver oil, and saw decidedly better results than when it was omitted. He had remarked before that he had also tried the other salts of benzoic acid, potassium, and sodium, but without equal benefit. He then determined to combine the lime with the acid, and accordingly had some of this salt made for him; the results of the trial were highly satisfactory. In regard to the diuretic action, he would say that he had seen a decided increase in the flow of urine, not only in pregnancy but in other cases.

The question in reference to the relationship of twin pregnancy to albuminuria opened up the whole subject of the causation of albuminuria in pregnancy, which did not legitimately come under discussion; but he would say that in many cases the pressure appeared to be the sole cause of the symptom. We know that in fibroid tumors pressure produces congestion of the kidneys and albuminuria: if we admit this as a cause in enlargement of the uterus from other causes, then in twin pregnancy there is greater cause for albuminuria than in single, because there is greater enlargement and greater pressure.

With regard to the diagnosis, he called attention to the fact that the case referred to by Dr. O'Hara was examined before the seventh month. There was enormous adipose enlargement of the abdominal walls, and, as was afterwards shown, amniotic dropsy, and it was only possible at that time to give a probable diagnosis. In the great majority of cases, towards the termination of the pregnancy we can make a diagnosis easily between single and twin pregnancy. This matter of diagnosis by external manipulation, although a comparatively recent teaching, has now become so thoroughly incorporated into the obstetric art that no thorough course of school teaching is without it. Not only should every student of medicine be taught it theoretically, but to be competent for a degree it should be a matter of individual clinical instruction in every first-class collegiate course. The English and American comprehensive treatises are defective generally in their handling of this important subject, while the French and German systematic treatises on obstetrics have many pages devoted to its details, and we have in the exhaustive monograph of Pinard of Paris, and even more thoroughly in that of our distinguished fellow-countryman, Dr. Mundé, this subject so fully handled and made accessible to the profession as to leave no excuse for its not being an art at the complete command of all the newly-made practitioners of medicine; and yet the lecturer was sorry to have to admit that the only medical school in Philadelphia where external palpation is at all taught as a means of diagnosis, or any stress laid upon it, except in rectifying malpositions otherwise discovered, is at the Women's Medical College, where it is not only thoroughly taught, but the students practised by their professor of obstetrics, regularly and compulsorily, upon the Pinard & Budin manikin, in the diagnosis of presentations and positions by external manipulation, and, as opportunity offers, upon the living subject in the hospital. It is to be hoped that before long the great schools of our city will furnish the same complete instruction.

In reply to a question about the solubility of calcium benzoate, he said that eight or ten grains could be dissolved in a tablespoonful of any syrup and water. It is soluble in the mouth, and has not an unpleasant taste. The other salts of benzoic acid cause a residual nausea from their lingering upon the palate, which is not the case with the calcium salt.

A conversational meeting of the Society was held at the Hall of the College of Physicians, Philadelphia, June 8, 1881, Dr. Albert H. Smith, President of the Society, in the chair. Dr. Carl Seiler read a paper on "A New Form of Galvano-Cautery Battery" (see page 749).

DISCUSSION.

Dr. A. D. Hall approved of the battery, and indorsed its claims for convenience of application. In a case of purulent otitis media, with perforation of drum of the ear, in which the stump of a polypus kept up the irritation,

he had applied the usual remedies without effect. He then thought of the galvano-cautery, and Dr. Seiler applied it with his battery with excellent result. This case demonstrated the prompt and efficient working of the battery in a most gratifying manner. This would be of great value in the treatment of fistula of the lachrymal sac, and is the only method that will cure this difficulty, the flow of the tears preventing the ordinary actual cautery from acting.

Dr. A. H. Smith noticed the convenience of use and portability of the apparatus, and said that any form of mechanism which tends to make the galvano-cautery more available would be of great service, especially in gynæcology. He had found the old forms of battery so troublesome and unreliable that he had adopted the Paquelin cautery, on account of its ease of management and comparative cheapness. It has, therefore, almost entirely driven out the moxas and actual cautery from surgery; and yet there are some cases of amputation of the cervix where an elevated position of the diseased mass, with firm fixation, and a close vulvar outlet, render its use difficult, and a galvano-cautery with wire écraseur, perfectly reliable and manageable, would be a great desideratum.

Dr. J. Solis Cohen took the opportunity of expressing his admiration of the mechanism by which the elements are lifted in and out of the fluid with a facility which was obtained in no other form of battery with which he was acquainted. He regarded it as a very great improvement over the ordinary galvano-cautery batteries. For ordinary purposes it supersedes the Paquelin *thermo-cautère*. The reason why galvano-cautery failed of general adoption before was because those using it often did not understand the physical laws of electricity; the battery would get out of order, and they would not know why. The best plan under such circumstances would be to call in the services of an electrician, who would put the battery in good order; the expense would be money well invested.

Dr. Blackwood regarded the form of office battery presented as a decided advance, the old form being expensive to get and to keep in good repair. The usual difficulty in batteries is on account of the connections, which get rusty and out of order.

Some years ago he published a communication in reference to constructing batteries, and showed how cheaply they could be made. Subsequently many letters of inquiry were received, showing the interest taken in the subject. He subsequently explained in the *Medical and Surgical Reporter* how to make a cheap galvanic battery.

He saw an advantage in connecting below the fluid rather than above it. In the ordinary plan it is exposed to the fumes of the fluid, and the connection may thus be entirely eaten away. Of course, when this happens, the battery refuses to do its work until it is put in good order again.

Dr. Seiler, in reply to a question as to the maker of the battery and the cost, said that he made the one presented at a cost of not over five dollars, but it was rather rough. Flemming and Talbot, of this city, propose to make them shortly in an improved case, at a cost not to exceed that of an ordinary portable battery.

On motion, the thanks of the Society were tendered to Dr. Seiler for his interesting and valuable communication. F. W.

A conversational meeting was held at the Hall of the College of Physicians, Philadelphia, June 23, 1881, Dr. Albert H. Smith, President of the Society, in the chair. Dr. George C. Harlan read a paper on "Fatal Otitis" (see page 750), and exhibited a number of interesting specimens and preparations.

DISCUSSION UPON FATAL OTITIS.

Dr. Chas. S. Turnbull expressed his interest in the valuable paper, especially as it treats of such an important subject to the practitioner and illustrates the dangers of neglecting chronic suppurative ear disease. He would say a few words as to the pathology of abscess of the cerebellum accompanying chronic purulent inflammations of the middle and internal ear. Such are now generally recognized as occurring in connection with chronic purulent otitis media or interna, and are caused by the escape of pus through a perforation in the roof of the tympanum, or through the labyrinth and internal auditory canal, and are the result of pressure. In several cases in which he had examined, and subsequently made post-mortem examinations, he had found a distinct abscess in the substance of the cerebellum, within a thoroughly organized abscess-wall, and enclosed in a pyogenic membrane. Politzer, Gruber, Zuckerkandl, Weber-Liel, and most of the Vienna and Berlin aurists, acknowledge that abscesses of this kind are generally caused by direct pressure, which causes breaking down of the cerebellar tissue, referring, of course, to those in which there is no direct extension of the inflammation. Too much cannot be said with regard to the danger of cerebellar disease as a result of neglected purulent otitis media: they may be fatal even when the internal ear is not at all involved.

As regards the use of strong solutions of nitrate of silver, the speaker could not approve, but rather deprecated, their use in such cases. The insufflation of powders is now used in preference to such applications. Experience has taught us to rely upon boracic acid chiefly, but iodoform or alum may also be employed with benefit. He would especially recommend *finely powdered* boracic acid insufflations in purulent disease of the

middle ear. Polypi, of course, should be removed, not by the forceps, but by the wire loop or snare of Wilde or Gruber. The reason that so few fatal cases are reported at present is that physicians of the present day, as a rule, have a much better knowledge of diseases of the ear, and conservative surgery is the rule rather than the exception. If boracic acid is used for insufflation, it should be finely powdered; coarse powders do more harm than good. When properly applied, it is one of the best antiseptic remedies we possess for the treatment of purulent inflammation of the middle or internal ear.

Dr. J. L. Ludlow said that he had treated a great many of these cases with discharge from the ear, and considered that there is a great deal of groping in the dark in regard to them. He had found experts, even, making serious mistakes in diagnosis. He referred to a case of a physician who, after an attack of pneumonia, suffered with agonizing pain in his ear, radiating also from the mastoid process down the cervical region and to the front on the face. Two specialists saw him in consultation with Dr. Ludlow, but could not agree as to the existence of mastoid inflammation. The speaker found a swelling under the ear in the fossa, pressure upon which caused bulging in the floor of the auditory meatus. The next morning the abscess opened spontaneously in front of the membrana tympani. Here was a case that narrowly escaped trephining of the mastoid cells, but entirely recovered without it.

Many cases of cold in the ears get well without special treatment. In Barbadoes the negroes squeeze cockroaches into the ear for earache. The treatment in civilized communities varies. He himself usually preferred a preparation of hyoscyamus in oil; he had great confidence in it, as it gives great relief.

Dr. C. B. Nancrede reported a case of a man, fifty years of age, who entered the Episcopal Hospital with facial paralysis, and an extensive abscess involving the left temporal region, though not much in advance of the ear. The temporal bone was principally affected, and, upon examination, was found to be bare for several inches, especially over the mastoid process. The patient was completely deaf in the left ear. After free opening and drainage was accomplished, he was completely restored, the bone became covered, and he regained his hearing.

Dr. F. Woodbury observed that an acute otitis media often caused necrosis of the chain of bones and permanent damage to hearing in the course of a few days, and he considered it highly reprehensible for a physician to simply order some drops for the earache without examining into the condition of the membrana tympani, which is accomplished with facility even in young children. He had been surprised by the curative effects of simple treatment upon perforations of the membrane, when recent. He urged that the recommendations of the paper might not pass unheeded: any patient suffering with a discharge from the ear should be regarded as being threatened with fatal cerebral disease.

He mentioned the case of a lady patient, who, as a child, and while under the care of a homœopathic physician, had a neglected ear-discharge following scarlet fever. When the speaker examined her ears, he found that the membrane and chain of bones were entirely gone on both sides. Although slightly deaf, her hearing was fairly preserved; some days she could hear better than others. She did not use an ear-trumpet.

In conclusion, the use of potassium permangate solution was opposed by the speaker on account of the oxidizing and hence caustic effects of the salt. He believed that he had seen perforation of the delicate membrane of the tympanum due to the well-known action of the salt upon organic matter. The experience of the lecturer was requested upon this subject.

Dr. Harlan, in closing the discussion, said that there was one important point in the anatomy of the petrous portion of the temporal bone that deserves discussion,—*i.e.*, the asserted facility of communication between the internal ear and the internal auditory meatus, whether or not fluid does pass readily from the labyrinth to the general cavity of the skull. He referred to the statement of Hyatt, that the fluid in the internal ear has the same composition and is probably identical with the cerebro-spinal fluid, and the conclusion that in the normal ear it passes readily from the labyrinth to the brain. After careful examination of the skull in a case which had suffered with a chronic discharge, and in which he had observed particularly that the labyrinth was entirely covered, but was not carious, he was unable to find any openings in the cribriform fascia, or at least none large enough to permit the passage of fluid. The colored injection, however, passed readily through it. He then procured a normal temporal bone and poured the liquid colored with aniline blue into the labyrinth, and with a tube endeavored to force the fluid through, but found that there was not the slightest passage of the injection. He was therefore led to conclude that in the former case the communication was due to a pathological cause.

In regard to the potassium permanganate, properly diluted, he did not think that it would cause perforation of the membrane, but it is generally caused by the disease for which the remedy is used.

In reference to the mistakes of aural surgeons, they being like other men, he supposed that they cannot claim infallibility, but thought that they probably would be less likely to make errors of diagnosis in a class of cases with which they are continually

brought in contact than physicians, who see such cases only occasionally. The instance quoted by Dr. Ludlow was a beautiful illustration of a case of mastoid abscess opening spontaneously. This was a rare result; but the patient might have been saved much suffering if the operation referred to had been performed early in the case. The operation is not a serious one, and has been frequently performed, with only one fatal result, which was not attributable to the operation. Where there is purulent inflammation in this region, it is only common sense to lay open the part freely and permit the discharge of pus. There is no portion of the human body in which it is more important to give exit to pus than in disease of the mastoid cells.

A vote of thanks was unanimously tendered to Dr. Harlan for his instructive and interesting paper.

EXAMINATION OF THE SCHUYLKILL WATER.

Dr. Leffmann read a "Note on Schuylkill Water in its Hygienic Relations." (See page 756.)

Dr. C. K. Mills inquired as to the effect of the cemeteries upon the banks of the Schuylkill upon the potability of the water and its wholesomeness.

Dr. Blackwood called attention to the amount of sewage that flows into the Schuylkill from the large towns which it drains in its course. For instance, the entire drainage of the Little Schuylkill region goes down the two rivers. So impure is the stream that near Pottsville the fish cannot live in it,—perhaps owing to its containing sulphuric acid. Doubtless it settles and purifies itself a good deal by oxidation on its way down; but it receives the drainage of Norristown, Spring Mills, Conshohocken, and numerous other populous places nearer the city, so that the amount of drainage coming down the Little Schuylkill region makes very little difference.

With regard to the Delaware water, he inquired where the sample was taken from. Above Trenton the Delaware must be comparatively pure, but near Kensington it is very foul. Gunner's Run is simply an open sewer, and the supply for the water-works is pumped directly from its outlet for delivery in Kensington for drinking-purposes.

With reference to the cemeteries, the popular idea is that the nature of the ground and the direction of the rock-strata at Laurel Hill carry the drainage away; but much of it goes into the Schuylkill, as does that from Glenwood and West Laurel Hill. Under ordinary circumstances a dead body affects the ground only to a very slight extent; but in rainy seasons there is washed into the Schuylkill a great deal of impurity from the cemeteries.

Dr. Leffmann, in reply, said that Laurel Hill does not seriously pollute the water. The Park lines extend for five miles along the river, which gives it time to purify itself before reaching Fairmount. In this distance there is only one stream that really bears sewage, and that empties into the river near the Girard Avenue Bridge.

The samples examined were taken from hydrants, which is the best way of getting at the water as delivered.

The Schuylkill in its upper part contains much iron and sulphuric acid; it then passes through a limestone region, where these are carbonized and precipitated, carrying with them organic matter. It is further purified by the slow current and the breadth of the stream, especially near Manayunk, which absorbs the air and favors oxidation.

On motion of Dr. H. H. Smith, the Committee on Hygiene were authorized to publish the results of Dr. Leffmann's examination of the water-supply of Philadelphia. The thanks of the Society were also tendered him by the usual vote. F. W.

REVIEWS AND BOOK NOTICES.

THE FIRST BABY: HIS TRIALS, AND THE TRIALS OF HIS PARENTS. By JEROME WALKER, M.D., Physician to the Sea-Side Home for Children, Coney Island, etc. New York, Brown & Derby, 1881. 12mo, pp. 203.

A companion book to "Helen's Babies," we should judge from the style and contents. We learn from the introduction that the present work is a revised edition of a former book by the same author, called "How We raised Our Baby," which has enjoyed some popularity. Dr. Walker takes us into an imaginary family circle, gives all the nursery tattle and old wives' gossip connected with the advent and early months of baby-life, and draws a picture of domestic felicity which the hardened bachelor may well chuckle with self-gratulation at having escaped. Amid this chaff certain grains of medical wisdom are asserted to lie concealed. We have not, however, found such, and would recommend lay and medical readers alike to abjure this gallimaufry in favor of any one of the really scientific and practical little books on the care of children which have recently appeared.

A TREATISE ON CONTINUED FEVERS. By JAMES C. WILSON, M.D., Physician to the Philadelphia Hospital, etc. With an Introduction by J. M. Da Costa, M.D. New York, William Wood & Co., 1881. 8vo, pp. 365.

This excellent and practical treatise is one of "Wood's Library of Standard Medical Authors," and is above the average even of that well-selected series. Simple continued fever, influenza, cerebro-spinal fever, enteric or typhoid fever, typhus fever, relapsing fever, and dengue are each treated of in successive chap-

ters with as much fulness as the space allows, and with a judicious mingling of the scientific and more purely practical. Dr. Da Costa's introduction is a graceful exordium to the work of his younger professional brother, and, while nothing more than a brief account of this distinguished physician's personal views as to the general management of fever cases, gives a pleasing *imprimatur* to the work following.

A Practical Treatise on Impotence, Sterility, and Allied Disorders of the Male Sexual Organs. By Samuel W. Gross, A.M., M.D., Lecturer on Venereal and Genito-Urinary Diseases in the Jefferson Medical College of Philadelphia, etc. With Sixteen Illustrations. Philadelphia, Henry C. Lea's Son & Co., 1881. 8vo, pp. 174.

Dr. Gross's aim has been to supply, in a compact form, practical and strictly scientific information especially adapted to the wants of the general practitioner. He considers the subjects of impotence, sterility, spermatorrhœa, and prostatorrhœa in succession, giving illustrative cases from time to time, with a full account of the treatment. Dr. Gross considers that sterility in the male has not received so much attention as it deserves. In one unfruitful marriage out of six the male is at fault. A peculiar theory of the author, and one the validity of which we fancy will not be conceded by some other specialists, is that masturbation is the cause of stricture.

GLEANINGS FROM EXCHANGES.

Milk Indigestion in Young Children. —Dr. Eustace Smith, in an article on this subject in the *British Medical Journal* (vol. i., 1881, p. 877), says that when indigestion is due to catarrh of the stomach it is readily amenable to treatment. All that is necessary is to put a stop to the milk for a day or two, and to clear away the curd by a full dose of castor oil. If, however, the fault be in the milk, and not in the digestive organs of the child, some change in the method of feeding is indispensable. In one case where curdling took place, with resultant griping and indigestion, and where various remedies had failed, Dr. Smith at last adopted the plan of giving the child barley-water from a bottle immediately before he took the breast, in the hope that by this means the milk might be diluted directly it reached the stomach. This method succeeded perfectly, and the child had no further unpleasant symptoms.

In cases of gastric catarrh, when the complaint is acute and severe, vomiting is usually the most prominent symptom. Under such circumstances milk becomes a positive poison, and no hope of alleviating the symptoms can be entertained while this diet is persisted with. In the case of an infant two months old, brought up by hand and fed upon milk and barley-water, uncontrollable vomiting and diarrhœa had reduced it to the last extremity. Dr. Smith directed a weak mustard poultice to the epigastrium. The milk was stopped and the child fed with weak veal-broth and thin barley-water mixed together in equal proportions and given cold at intervals with a teaspoon. A few drops of brandy were given occasionally, as seemed desirable. As a result of this treatment the vomiting stopped at once, and the child, when seen three days afterwards, was found to be much improved, and was cured by the end of a few days' further treatment. The most important part of the treatment in this case was the substitution of veal-broth for milk. Directly the supply of fermentable matter was stopped, fermentation ceased, acid was no longer formed, and the digestive organs returned to a healthy condition. Here the derangement was acute.

Another case of a chronic character is cited by Dr. Smith, where a little girl ten months old had been fed first with milk, then wtth farinaceous food, and later with beef-tea. She vomited everything and was growing extremely emaciated. Such a case is treated, he says, by restricting the diet to equal parts of weak veal-broth and thin barley-water, given cold, in small quantities at a time, by warmth to the belly and extremities, by perfect quiet, and by suitable remedies. The best sedative is Fowler's solution,—half a drop for the dose,—given with a few grains of bicarbonate of sodium in some aromatic water. After a few days of such treatment the power of digesting milk usually returns. But at first it should be given sparingly, freely diluted with barley-water, and only once or twice in the day.

Looseness of the bowels is a common consequence of milk indigestion. Such cases, seen in the early stage, are sometimes spoken of as cases of "inactive liver," the white stools being supposed to be merely the result of insufficient biliary secretion. Cholagogues are, however, in such cases quite useless. The stools are white because they consist of curd mixed with the farinaceous matter which is usually given in large quantities at the same time; and their character can only be improved by a complete change of diet. When a chronic diarrhœa is regularly established, the cases are very often called "consumption of the bowels." It is needless to say that they have no relation at all to "consumption," but are a purely functional derangement, a chronic catarrh of the bowels, excited and maintained by indigested food.

In another case cited by Dr. Smith, where a child of fourteen months was wasting away with chronic diarrhœa, the diet of milk and sago was changed, and the child was fed in-

stead with whey and cream, veal-broth and barley-water, yolk of eggs, and "Mellin's food" dissolved in barley-water. Iron and arsenic were also administered, and later quinine and cod-liver oil. Dr. Smith does not think well of beef-tea for children, and prefers veal-broth.

WHITLOW.—In a clinical lecture on whitlow (*Medical Times and Gazette*, vol. i., 1881, p. 667) Mr. Christopher Heath says that the subject is meagrely treated of in the text-books. If met with in the earliest stage, when the finger has just begun to redden and tingle, a twenty-grain solution of nitrate of silver, or the silver stick wetted and lightly pencilled over the affected part and a little beyond, checks it at once. When the whitlow is a little more severe,—that is, when pus forms about the nail or the tip of the finger,—the cuticle, which is insensitive, may be incised. Occasionally, however, when a foreign body has found its way beneath the nail, pus forms there and gives rise to excruciating agony from the tension beneath unyielding structures. Judicious cutting away of the nail will relieve this if near the margin; but if near to the base, it is much better to pare down to the nail with a sharp knife until the matter is let out than to resort to the unnecessary cruelty of removing the entire nail.

The third kind of whitlow is really an acute necrosis of the terminal phalanx, following periostitis and suppuration beneath the periosteum, just as it does in the case of a long bone. A very slight injury—the prick of a needle or a pin—may set it up. After some hours' uneasiness, the pain becomes acute and throbbing, and entirely prevents the patient sleeping. If timely relief is not given, pus will very slowly make its way to the surface of the finger, but never up the sheath of the tendons, and, when discharged, will leave the greatest part of the phalanx bare and dead behind it. A timely and free incision is the only mode of saving the phalanx, and cannot be resorted to too early; for, if no pus be present, the inflamed periosteum will still be divided with great relief to suffering. The finger should be held firmly on a table, and the surgeon, entering his knife just above the transverse interphalangeal mark in the skin, should cut boldly down to the bone in its whole length from base to apex. When, as so often happens, these cases have been treated domestically with "soap and sugar" and poulticing until the end of the finger is riddled with sinuses, there is nothing to be done except to extract the necrosed phalanx as soon as it is loose and to bring the finger into shape by careful water-dressing applied in strips. The base of the phalanx usually survives, giving a point of attachment to the tendons.

Inflammation of the skin and subcutaneous tissues may occur in any part of the finger. Incisions must here be made with care, so as not to open the theca or sheaths of the tendons, which then invariably slough, and the patient is left with a useless finger. For this reason incisions on each side of the finger are safer than one in the centre, that may unawares let out the tendons, which will look perfectly healthy at the moment, but soon become sodden and softened.

The synovial sheaths of the flexor tendons of the thumb are often, though not always, in direct communication with the synovial membrane of the annular ligament of the wrist, and hence pus is rapidly conducted in this way up to and, if not relieved, into the forearm.

There is much difference in the importance of saving the different digits. The thumb must be saved at all hazards. The middle and ring fingers are comparatively unimportant, and, if stiff, are apt to be in the way. A stiff forefinger is better than none.

EARTH-WORMS AND ANTHRAX.—A report has been made by M. Villemin in the name of a commission appointed by the Académie de Médecine to investigate the statements of M. Pasteur as to the presence of the germs of anthrax bacteria in the soil, and their transportation by earth-worms. These statements of M. Pasteur have been contradicted by M. Colin, of Alfort. In the investigations of the commission, they first inoculated five guinea-pigs with earth taken from the soil over a trench in which animals dead of anthrax had been buried twelve years previously. All the guinea-pigs died,—the first four from septicæmia, the fifth from well-marked anthrax; and the latter presented numerous bacteria in the blood of the heart and the spleen, which organ was considerably enlarged. A second similar series of guinea-pigs were inoculated with earth from above a pit in which animals dead of the disease had been buried for three years. The first four of these also died of septicæmia, and the fifth of anthrax, with characteristic bacteria. A third series were inoculated with "virgin soil,"—*i.e.*, earth from a spot in which, within living memory, no animal dead of anthrax had been buried. All of these continued well, presenting only at the point of the inoculation a small nodosity the size of a nut and consisting of an abscess enclosed in a pyogenic membrane. The first two of these experiments with the suspected earth were repeated, six guinea-pigs in all being inoculated. Of these all died,—five of septicæmia, the sixth of anthrax. Two other guinea-pigs were inoculated with blood from the animals to which anthrax had been communicated in the first two series of experiments, and both died of the same disease. A drop of blood taken from the ear of one and "sown" in some decoction of food reproduced pure and abundant anthrax bacteridia. Some worms were also taken from the earth over the pits in which the animals had been buried three and twelve years before, and

their excrement (the worms being still alive) was diluted with a little distilled water, and with it three guinea-pigs were inoculated. Of these two died of septicæmia, and the third from anthrax. Other three guinea-pigs were inoculated with the excrement of worms taken from the soil beneath which, during the Commune, human bodies had been interred. One of the guinea-pigs died of septicæmia; the other two continued well. Lastly, the excrement of worms collected over the trench in which the animals had been buried for twelve years, and treated by "cultivation," gave rise to a rapid production of bacteridia, which, inoculated into two guinea-pigs, caused the death of both by anthrax. The experiments and report thus give a triumphant corroboration to the assertions of M. Pasteur.—*Lancet*, vol. i., 1881, p. 877.

FAURÉ'S SECONDARY OR STORAGE BATTERY FOR MEDICAL USE.—Dr. George Buchanan (*British Medical Journal*, vol. i., 1880, p. 914) is the first practitioner to have used the new storage battery, the invention of which was hailed with so much enthusiasm by Sir William Thompson, the physicist, a month or so ago. The new battery consists of a cylindrical vessel of lead nine inches high and five inches in diameter, with a leaden bottom, but open at the top; in this is packed a kind of cushion which has the power of absorbing electricity. To this vessel are attached the poles of a working battery; and so long as the connection is maintained, the vessel accumulates the electricity flowing into it. When charged, it can be detached from its connection and kept for a long time, or carried from place to place like the jars of compressed carbonic oxide used for anæsthetic purposes. When required for use, the cushion, which should always be kept moist, is wetted with dilute sulphuric acid, and wires connecting are attached to its poles, when it is converted into a powerful battery. Dr. Buchanan has recently removed a nævoid tumor of the tongue by means of this battery, using a platinum wire écraseur. It can be managed without the least difficulty.

SKIN-GRAFTING FROM THE DEAD SUBJECT.—Dr. Girdner (*New York Medical Record*) has done this with success in a burned patient, the grafts having been taken from a suicide six hours after death.

MISCELLANY.

PRIZES OF THE ALUMNI ASSOCIATION OF THE ALBANY MEDICAL COLLEGE.—The following prizes are open to competition during the coming year: 1. A "Surgical Prize" of one hundred dollars for the best essay on "Colles' Fracture: its Pathology and Treatment," to be accompanied by a pathological specimen illustrating the fracture with or without dislocation of the ulna, or a careful dissection of the hand, wrist, and forearm. 2. A "Surgical Prize" of fifty dollars for the second best essay on the above subject. 3. A "March Memorial Prize" of one hundred dollars for the best essay on "The Pathology and Treatment of Morbus Coxarius." 4. An "Armsby Memorial Prize" of one hundred dollars for the best essay containing "A Minute Description of the Genito-Urinary Organs of the Male," together with a carefully-dissected specimen of the same. 5. A "McNaughton Memorial Prize" of one hundred dollars for the best essay on "Antisepsis in the Treatment of Diseases."

Essays and specimens, designated by a motto and accompanied by a sealed envelope enclosed with the same motto and containing the name and address of the author, must be sent to the Secretary, Dr. W. G. Tucker, by the 14th day of February, 1882. The committee to examine the essays for this year will consist of Drs. A. Van Derveer, J. S. Mosher, and Lorenzo Hale; and they reserve the right to reject any or all of the essays if not deemed worthy.

All specimens are to be deposited in the New Museum of the College, properly labelled.

OBITUARY.—Dr. Maurice Raynaud, the distinguished and eloquent French physician who was to have delivered one of the addresses before the late International Congress in London, died quite suddenly on the 29th of June, in the forty-seventh year of his age.

Dr. Raynaud was a cultivated physician, having written several medico-literary essays, among others one on "The Physicians of Molière's Time," which was quite well known. He was the most eminent and proper candidate for the chair of History of Medicine in the Faculty of Paris when this became vacant a few years since; but Raynaud was a man of decided religious convictions, and this, in the eyes of the atheistic bigotry which miscalls itself "liberalism," and which just now rules France, was sufficient to condemn a man, however illustrious by his merits.

TREATMENT OF RINGWORM OF THE HEAD.—Dr. Besnier recommends the following:

℞ Acidi boracici, gr. xv;
Sulphur. sublimat., gr. xv;
Vaselini, ℥j.

GLYCEROLE OF THYMOL.—

℞ Thymol, 1.0;
Glycerin, 25.0;
Alcohol, 25.0;
Water, enough to make 500.0.—M.

Useful in pityriasis.

THE USE OF A COMBINATION OF SALICYLIC ACID AND CAMPHOR AS A SURGICAL DRESSING is suggested by Dr. Lajoux, with the idea that the salicylic acid would act on the albuminoid ferments, and the camphor on the organisms of wounds. The compound has been employed by Dr. Heural, it is said, with satisfactory results. It was far more effica-

cious than any other application in a case of ulcerated lupus in a syphilitic patient, the sores immediately assuming a more healthy aspect and soon healing. A phagedænic ulcer of the fourchette which had lasted for six months was healed in a fortnight.

SIMPLE REMEDY FOR CHAFE.—Bathe parts well in tepid water, dry well with soft cloths, and apply, by means of a soft sponge or cloth, the following:

℞ Zinci acetatis, gr. xv;
Morphiæ acetatis, gr. ij;
Glycerin., aq. rosæ, āā ʒij.—M.

Ft. sol.

Sig.—Apply to chafed parts twice or thrice a day.

ADMINISTRATION OF MEDICINE BY THE NOSTRILS.—By Dr. Fernet's suggestion, the patient is laid on his back, with head and shoulders slightly raised by pillows. The liquid is to be poured slowly into the back part of the nares by means of a very pointed spoon or other agent, and when it reaches the pharynx it induces a movement of deglutition. Adroitly performed, food may be given in this way as well as by the mouth.

STYPTIC COLLOID.—

℞ Collodion, 100.0;
Carbolic acid, 10.0;
Tannic acid, 5.0;
Benzoic acid, 5.0.

Mix the ingredients in the above order. It instantly coagulates blood, forming a consistent clot under which wounds will readily heal.

CURE FOR RINGWORM (MORRIS).—

℞ Thymol, 0.5 to 1.0;
Chloroform, 4.0;
Olive oil, 12.0.—M.

The thymol destroys the fungus, the oil prevents irritation and rapid evaporation, while the chloroform facilitates the absorption of the active ingredient by acting on the sebaceous glands.

WHAT IS FILTH?—The English health authorities have decided that decaying vegetable and animal matter, rotten fish, the refuse of slaughter-houses, and human excrement are to be regarded as "filth." "Ordinary stable and cow-house dung," however, it appears, does not come under this designation. Good news to those who consider stable odors "healthy."

AN IMPROVEMENT IN THE PRESERVATION OF DEAD BODIES AT THE MORGUE.—The municipal authorities of Paris have adopted the refrigerating apparatus of MM. Nignon and Rouart, at a cost of about ten thousand dollars. Bodies are frozen and can then be kept on view indefinitely without decomposition. The atmosphere of the Morgue is also much improved.

AN UNNECESSARY SCARE.—Lincoln & Bennet, the famous London hat-makers, assert that no change for the smaller has taken place in hat-measurements of late years.

NOTES AND QUERIES.

PHILADELPHIA, August 17, 1881.

EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—My mite of contribution to the discussion on "Vaccination" at the meeting of the Philadelphia County Medical Society, as printed in the *Times* of August 13 (p. 729), is certainly very "*funny-graphically*" reported. I said, or *tried to say*, that I had used animal vaccine very largely, and had seen many of the spurious vaccinations described by Dr. Welch. They had occurred in the use of every form of animal vaccine (crusts, cones, quills, and points), procured from different sources of supply. As a curious fact, I stated that I had seen the "cowpox raspberry" and a typical vaccine vesicle side by side on the same arm and resulting from the use of the same point of virus. As a contribution to the value of vaccination by the much-abused public vaccine physicians, I stated that in a series of over six thousand successful vaccinations in the district under my care I had been able to trace only ten cases of *varioloid* occurring subsequently to the operation. It is easily to be seen how the printed report could be "fixed up" from the above. But as I have long advocated the *exclusive* use of animal vaccine in the public service, and have been a very large user of it in public and private practice, and with generally satisfactory results, this note of correction seems plainly due from Yours very truly,

HENRY F. BAXTER,
242 Catharine Street.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM AUGUST 6 TO AUGUST 20, 1881.

MCKEE, J. C., MAJOR AND SURGEON.—By direction of the Secretary of War, the leave of absence on Surgeon's Certificate of Disability granted in S. O. No. 177, August 19, 1880, is extended three months. Paragraph 3, S. O. 189, A. G. O., August 18, 1881.

WHITE, C. B., MAJOR AND SURGEON.—Died at Wilton, Conn., August 10, 1881.

STERNBERG, GEO. M., MAJOR AND SURGEON.—Relieved from duty in connection with the National Board of Health, to proceed from Baltimore, Md., to San Francisco, Cal., and report to Commanding General, Department of California, for assignment to duty. S. O. 182, A. G. O., August 10, 1881.

HUBBARD, V. B., ASSISTANT-SURGEON.—Promoted to the rank of Major and Surgeon in the Medical Department, to take effect from the 10th of August, 1881, vice White, deceased.

CORSON, J. K., CAPTAIN AND ASSISTANT-SURGEON.—The leave of absence granted him in S. O. 61, May 31, 1881, Department of Arizona, extended two months. S. O. 179, A. G. O., August 6, 1881.

HALL, J. D., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for one month, with permission to apply for three months' extension, to take effect on final adjournment of G. C. Martial, of which he is Judge-Advocate. S. O. 141, Department of Dakota, August 4, 1881.

SEMIG, B. G., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for six months, with permission to leave the Department of the Platte. S. O. 182, c. s., A. G. O.

PERLEY, H. O., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for four months. S. O. 178, A. G. O., August 5, 1881.

BUSHNELL, GEO. E., ASSISTANT-SURGEON.—Granted leave of absence for fourteen days. S. O. 145, Headquarters Department of Dakota, August 9, 1881.

BUSHNELL, GEO. E., ASSISTANT-SURGEON.—Relieved from duty at Fort Yates, D.T., and to report to Commanding Officer, Fort A. Lincoln, D.T., for temporary duty, on expiration of leave of absence. S. O. 146, Headquarters Department of Dakota, August 11, 1881.

PHILADELPHIA, SEPTEMBER 10, 1881.

ORIGINAL LECTURES.

CLINICAL LECTURE ON DIPHTHERIA.

BY JOHN A. LARRABEE, M.D.,

Clinical Lecturer on Diseases of Children, Hospital College of Medicine, Louisville, Ky.

GENTLEMEN,—I find in the waiting-room this patient, who, though not an infant, illustrates a class of cases to which I wish to direct your attention on this occasion. This patient complains of sore throat,—a term which does not strongly appeal to our sense of the propriety of technical terms, but which, in this case, is nevertheless suggestive. This enlargement here at the angle of the jaw is apparent to you all, and by palpation I find the sterno-cleido-mastoid muscle is elevated by it and there is some stiffness of the neck. Inspection shows the pharynx to be of a dark mahogany-red color and the tonsils studded over with little points of whitish material; and from this examination I take it for granted that the questions I shall now ask will be answered in the affirmative.

"Have you pain in the head?" "Yes." "In both ears?" "Yes." "In which is it greatest?" "In the right." (You observe, gentlemen, the severest pain corresponds to the side most swollen.) "Have you pain in the back?" "No." "Have you pain in your limbs?" "No." "Chilly sensations?" "No." "Do you feel weak and exhausted?" "Yes; have felt so since last Tuesday."

That history, gentlemen, in connection with the local manifestations, is sufficient.

In the first place, our remarks will bear upon that disease known as diphtheria. Perhaps no more important subject can engage our attention for a time. Diphtheria is a disease by no means new. Attention to the literature of the past shows it to have been in existence from the most ancient times. Notwithstanding this is true, authorities in medicine are not at the present time in harmony as to its etiology. Occurring as a sporadic disease, while it may be severe, it seldom results fatally; when it prevails in an epidemic form it is disastrous to human life in proportion as it is a serious malady in sporadic cases.

In regard to the important subject,—its etiology,—in the first place the question arises, is it a contagious disease?—that is, will contact with the breath of the affected person or with the parts produce the disease in a person who is perfectly well? I may as well forestall all argument here and say it will. Diphtheria is a disease of a mucous surface, and is capable of being communicated, as diseases of the mucous surfaces generally are. Even severe catarrhal inflammation attended by secretion of pus may be communicated, and these are communicated with certainty also from one to another.

A very important question as to the commencement of the disease relates to its constitutional or local origin. Is the disease local first and then constitutional, or first constitutional and then local? In the settlement of this question we have the key not only to the treatment, but perhaps to the etiology.

Oertel and many others have found, or think they have, the origin of this disease by the aid of the microscope, in the presence of myriads of little living organisms known as bacteria; and they have even classified these into different varieties as we would classify the different animals. It is supposed by these observers that these organisms, coming in contact with the mucous membrane, produce that which we see in this throat, viz., a diphtheritic patch or false membrane. This theory, then, would necessarily substantiate the local origin of the disease. But, say these observers, the disease, usually at first local and afterwards constitutional, may be first constitutional and afterwards local, because these bacteria may be drawn in with the inspired air and then come out at the throat.

It is best sometimes, in the consideration of these subjects, to group diseases; and I sometimes think the study of diseases and of medicine generally, and especially clinical medicine, is rendered difficult by segregation rather than aggregation. There are certain diseases which should be always regarded in one class, and it is very probable that future investigations will demonstrate that they are due to similar causes. Thus, I would place in one category erysipelatous inflammation, hospital gangrene,

and diphtheria, these constituting a class of diseases which are local and then constitutional, or *vice versâ*. The first proposition admits of demonstration, the last is probably capable of proof.

Take, for example, erysipelas,—a disease which presents itself upon the surface of the body, and generally upon that part of the body most exposed,—not only upon the head, but upon that part of the head most exposed,—the face, and, further, most frequently it appears upon the most exposed part of the face,—the nose. The favorite seat of idiopathic erysipelas is upon the side of the nose. It is a rare thing to find erysipelas attacking parts habitually covered, constantly protected; and when we do, we commonly find associated with it some solution of continuity in which a germ could have been deposited: therefore the proof is in favor of the germ theory of the origin of erysipelas.

Since, then, the atmosphere in which we move and live and have our being is laden with germs capable of producing disease, we are provided by nature with a covering to protect us.

Now, a man who has an erysipelatous patch upon his face frequently notices it before he feels the constitutional symptoms. He consults you, and you ask him questions like these:

Are you sick? No, sir. Have you had a chill? No, sir. Vomited? No, sir. Had no backache? No, sir. Not a single constitutional symptom; but in six hours he will have suffered them all.

Now let us go into a hospital ward and find an individual with a simple wound. To-day it is clean, healthy, red, and granulating; to-morrow it may look dry and free from the laudable pus which bathes the granulations, and a little mycelium scale has formed over it. Now, if you are keen you detect in that condition incipient gangrene. Then, if treatment be not at once instituted, in a short time he has the waxy cast of skin, the pallor, the headache, and the exhaustion. Here we have another form of local disease which afterwards becomes constitutional.

Now, the idea in regard to bacteria seems to me to be a little overdrawn. It seems to me that observers in the future will discover that they have found results rather than causes, inasmuch as from the teeth and gums in health you may get as many bacteria as you can in diphtheria.

Now, how are we able to detect a case of diphtheria? In this case at present the local symptoms are not so well marked, but four days ago had you looked into this throat they would have been distinctly manifest. Let me caution you, gentlemen, to be on the alert for these cases. Whenever there are swollen glands, muscular stiffness, lassitude, headache, an increase of temperature without an apparent cause, examine the throat. Now in regard to differentiation. Is every case of sore throat to be regarded as diphtheria? Certainly not. Then what constitutes the disease? Some of you have practised medicine, and perhaps you have lost a severe case in which were present, in addition to the symptoms I have mentioned, those which accompany the more severe forms of the disease. Now, because you have had such a case, if you are to make it the type by which all other cases must be measured, you will be disappointed. The fetid odor of the breath, the muscular trembling, and the paralysis which sometimes succeeds the attack, are not essential conditions before the disease can be said to exist. With such a standard for diagnosis, you will fail to recognize many of the milder forms of the disease. The attempt has been made to settle this question by saying there are two or three different kinds of diphtheria, two or three varieties of syphilis, scarlet fever, and measles. Now, there is a syphilis, and but one syphilis; the same is true of scarlet fever and measles; but these diseases manifest themselves differently in different constitutions. A seed planted on a hill-side produces one kind of stalk, while the same in a valley produces another. The phases of these diseases will be as varied as the dissimilar systems in which they are implanted. The failure to recognize this fact, along with an insufficient knowledge to render differentiation accurate, has led some writers to recognize a catarrhal diphtheria, while others say a diphtheritic. Such a multiplication of diseases is as unwise as it is unnecessary. Those cases presenting the combination of local and constitutional symptoms will in all gradations, from the mildest to the severest types, be recognized by him in whose mind the features of the disease have been stamped by study and observation as readily as the different nationalities and races of men are distinguished.

In regard to the supposed cause of this disease in cities, as for instance in the epi-

demic which has lately prevailed in Brooklyn and some parts of Massachusetts, where the boards of health have levelled all their blows at the drain-pipes, we may remark that, like a keen hunting-dog, having struck a good scent they stick to it. Having traced such connections between typhoid fever and bad drainage, the tendency is to run everything in that direction.

Out in Leadville, Colorado, I understand, diphtheria rages terribly sometimes. I do not suppose there is a water-closet in the place, much less a sewer. Diphtheria prevails where this gas does not exist.

There is an animal poison capable of reaching into every habitable portion of the globe, and generated wherever human beings have an existence, and that is the poison that results from overcrowding. This poison is generated where miners come together in camps, in soldiers' barracks, wherever people are congregated together. The human family is not different from the rest of animal life in this respect. Every farmer knows the deleterious result from penning up large numbers of sheep together.

Under the old system of fireplaces we heard less of these things, simply because all the ingenuity we could apply could not keep out the cold air; it had to have its supply of air.

Still another morbid condition remains to be differentiated from diphtheria. Essential differences exist between the two conditions, however, though each resembles the other very much in this, that both are characterized by false membranes. In the one case you have the history of the prodromal symptoms, the weariness, lassitude, and headache, and when you examine the pharynx you find the false membrane. The child with the croup is perhaps suddenly seized with stridor, a certain form of cough which, when once heard, is diagnostic for a lifetime, and, more than that, the difficulty in the case of the child with the croup seems to result entirely from the presence of the membrane. Further, this membrane once removed, an apparently healthy surface remains, and with its removal pass away also the symptoms of which the child complained. In diphtheria you may get off the last patch, and in twenty-four hours you may find new ones have substituted those removed. A difference is apparent, too, in the conditions left when nature effects the removal in the two instances. In diphtheria a granulated surface is seen after its removal; in croup a clean, apparently healthy surface. Why, then, if these diseases are so far apart, do we associate them? It is because they are at their extremes so widely different, yet when merged so like in all respects as to require a nice discrimination to decide between them. You may have the larynx invaded by a membrane, and with it all the evidences of diphtheria, and this diphtheritic form of croup is accepted as existing in the nomenclature of medicine. I maintain, gentlemen, that this is diphtheria and not croup at all. This I hold to be true whenever the tendency to recurrence of the membrane exists.

It occurs sporadically by preference in the winter months, and, while the young are especially its victims, it nevertheless is known to occur in extreme old age; while croup is a disease peculiar to infantile life. Again, in croup the deposition of the membrane is confined to the throat; while in diphtheria it may occur wherever there is a mucous membrane; and not only in these situations, but wherever the cuticle layer of the skin has been abraded, a diphtheritic patch may make its appearance. The membrane once expelled in croup, the disease no longer exists; in diphtheria your visits to the patient may have ceased, when all at once the disease is lighted up again, perhaps with renewed severity. Again, it is not unusual to find albuminuria in diphtheria, but very rarely is this manifestation present in croup.

One result among the sequelæ is to my mind pathognomonic as to the nature of the pre-existing disease; that is, paralysis: the involvement of the deeper structures which occurs interferes with the function of the nerves distributed to the parts. Usually the soft palate will hang flaccid for weeks or months. Nothing is more common than to have muscular weakness, if not paralysis, following an attack; a frequent seat of this muscular affection being found in the ocular muscles.

Now, as to treatment. If these points which I have brought forward be true, then nothing seems more conclusive than that our treatment should be both local and constitutional. The constitution, as I have said, is usually invaded before you are called to the case; and, since we regard it as a blood-dyscrasia, that constitutional treatment should be directed to supporting

the life of the blood-corpuscles. You attempt to secure that object in erysipelas and hospital gangrene; and this, as I have said before, is to be regarded as a disease of that type. A disease fraught with danger from the start, you may well imagine, requires not only accurate diagnosis, but prompt and decisive measures of treatment. Muriated tincture of iron, freely and persistently given, should form the basis of your treatment; its astringent property tends to prevent the organization of the membrane, while its effects upon the constitution tend to sustain the life of the patient, and thus enable him to throw off the membrane.

Another point I wish to speak of is this: the use of alcohol has been brought forward as something new by members of the medical profession. Any poison in the blood tending to destroy life by destruction of the blood-corpuscles, as well as by its debilitating effects upon local tissues, indicates a stimulant and a preservative. In alcohol we have the most powerful agent to prevent the destruction of animal tissues. Its stimulant property needs no comments. Give muriated tincture of iron, then, and alcohol with nourishment, but give the iron according to Col. Mulberry Sellers's directions for the use of his eye. Give along with this a whisky-toddy, a milk-punch, or, what is better, Christmas egg-nog, and don't withhold it out of fear of intoxication. The amount of alcohol that can be taken under these circumstances with immunity is astonishing. I have myself given a child, seven years old, a pint of whisky in twenty-four hours, without producing any symptom of intoxication. Now, these, gentlemen, are fundamental principles. Do not, I beg you, in such a case go off into speculations as to the value of carbolites. Carbolic acid is fit for nothing but to smell, and even for that purpose it may be very handsomely substituted. Neither is it necessary to give the sulphites, nor the hyposulphites, nor chlorate of potassium. We have recently seen from Dr. Jacobi, of New York, what we might have supposed before,—that is, that in excessive doses chlorate of potassium is a virulent poison. Then let me insist upon your strict adherence to muriated tincture of iron. Make it a religious duty, and your experience, if it correspond to mine, will give you cause for congratulation.

ORIGINAL COMMUNICATIONS.

DOES ETHER KILL?

BY JOHN GILLESPIE, JR., M.D.

IN the *Medical Times* of June 4, Dr. Roberts reports three cases of death from ether; he also quotes the cases collected by Dawson and by himself. The object of this article is to show that in every instance the death can be proved to have occurred either from disease or other morbid condition or as the result of improper administration of ether. That ether may kill is undeniable, but that it will cause death when properly administered is exceedingly improbable. The proper administration of ether consists solely in watching for the signs of danger: these signs are evident in every case in which ether is doing harm. The action of ether (depressing action) while producing anæsthesia is exerted on the respiratory centres, and death, if it be produced, is produced by paralysis of these centres.

The earlier writers uniformly asserted the perfect safety of ether. Bigelow* mentions but one case in which death followed etherization, and in that case he considers it very doubtful that ether was the cause of death. Snow† mentions two cases of reported "ether death," neither of which he accepts as being such. Dr. Snow, after reviewing his experiments, remarks, "I believe that ether is altogether incapable of producing the sudden death by paralysis of the heart which has caused the accidents which have happened during the administration of chloroform." On the same page is this sentence: "I hold it, therefore, to be almost impossible that a death can occur in the hands of a medical man who is applying it [ether] with ordinary intelligence and attention." Ether has been used in cases in which there was most serious disease of the heart; and I have seen cases of most intense asthenia, in aneurisms of the arch of the aorta, in which ether has been given without any ill effects occurring, either during the time of administration or afterwards.

Ether increases the force and frequency of the pulse and causes a rise of arterial pressure, and there is no serious impairment of this pressure until after decided

* Chapter on Anæsthetics, Piper's Surgery.
† On Anæsthetics.

embarrassment of respiration.* Dr. Roberts's quotation from the report of the Scientific Grants Committee of the British Medical Association† is evidently intended by the committee to apply to the pulmonary circulation, as it is only in connection with that system that anything is said about the depressing action of ether. The quotation which follows shows what the committee reported as to the effect of ether on the heart. After describing the method of conducting the investigation, the committee say, "It soon became evident that when chloroform is given in this way there is at once a most serious effect on the heart; the right ventricle almost immediately begins to distend, and the heart presently stops, with the right ventricle engorged with blood. The heart has often, in the case of rabbits, virtually come to a stand-still within a minute of the introduction of chloroform by the method described. The contrast was most striking when *ether* was used instead of chloroform. Ether may be given for an indefinite period *without interfering* with the heart."

The report also shows that fifty cubic centimetres of chloroform vapor administered in seventy-five seconds will cause complete stoppage of the pulmonary circulation, and that seven hundred and twenty seconds are required to re-establish it; while five hundred cubic centimetres of ether vapor given in two hundred and seventy seconds require only one hundred and eighty seconds for the restoration of the pulmonary circulation.

The report of the committee of the Royal Medical and Chirurgical Society‡ states that with ether "depressing action on the heart is either very slight or altogether absent."

In 1861, a committee of the Boston Medical Improvement Society, in its report upon the "alleged dangers of ether," stated that "there is no recorded case of death attributed to ether which cannot be explained on some other ground equally as plausible."

Almost all writers on anæsthetics mention the signs of danger during etherization, and state that if these signs are heeded the danger may be averted.

Jonathan Hutchinson§ asserts that it is to the use of complicated inhalers that the occasional ill effects of ether are due. Be this as it may, it is a fact that in many of the cases of reported death from ether, complicated inhalers have been used. Dr. Sawyer‖ declares that ether is as safe as an anæsthetic may be.

The first death reported by Dr. Roberts is that of a woman who was operated upon for fibrous anchylosis of the hip and knee. The woman had been etherized several times before without ill effects.

The autopsy showed that there was very general disease of the heart, although no particular part was very far advanced in disease. Sudden deaths occur every day from just as slight cardiac disease without any apparent exciting cause, while this woman had been greatly frightened not more than two or three minutes before etherization. The signs of cardiac weakness, feeble and rapid pulse, were first observed. The woman was breathing quietly and regularly until between forty and fifty minutes after the alarm was excited.

How can we reconcile this condition with the statements of the English Chloroform and Scientific Grants Committees?

Further, Dr. Roberts says that a "marked feature of this case was that almost every organ presented some noticeable change, although no organ had the characteristic appearance of any distinct disease."

Was this woman in a condition that would enable her to endure the shock of breaking up strong adhesions of the hip? After taking into consideration the condition of the woman before anæsthesia, the fright which she received, and the manner of death, it is but just to conclude that the death was caused, not by *ether*, but by *natural causes*. Particularly is this true since a death under similar circumstances —except that no anæsthetic was used—is reported by Dr. H. H. Smith.¶

The second case reported by Dr. Roberts is that of a man whose thigh was to have been amputated for necrosis of the femur. "There were many large sinuses, discharging large amounts of pus." Twenty grains of chloral hydrate were given to the man before etherization, and before the operation had been commenced collapse occurred and the man died.

Here was a man who was "run down"

* English Chloroform Committee.

by long-continued suppuration,—one by whom any cardiac depression would be badly borne. Therefore, when the well-known uncertainty of the effects of chloral is considered,—especially since the manner of death corresponds so well with that of death from chloral,—is it not very probable that death was caused by the chloral and not by the ether that was administered?

The third case reported by Dr. Roberts was that of a lad, aged nineteen years, with anchylosis of the knee, who was subjected to tenotomy and forcible straightening of the limb. After the operation, the boy rapidly recovered from the effects of the ether, and when he was removed from the operating-room was conscious and rational. Fifteen minutes after he was taken to his room he showed symptoms of asphyxia and congestion of the lungs, and died in one and one-fourth hours.

Here is another discrepancy. The Scientific Grants Committee's Report distinctly states that after complete stoppage of the pulmonary circulation and the consequent production of congestion of the lungs, this circulation is restored in three minutes; and yet in this case we have congestion of the lungs showing itself fifteen minutes after the boy had recovered from the ether. For years the boy had suffered with caries of the spine, which was very likely to have caused organic disease of the kidneys. At the post-mortem the lungs were found to be œdematous. The kidneys were not examined. It is to be regretted that the kidneys were not examined, because, as was said in the editorial comments on Dr. Roberts's paper, œdema of the lungs frequently occurs suddenly in the course of disease of the kidneys, and produces death in the same manner as this boy died. Here, then, is a physiological reason why death could not have been caused by ether, and the suggestion of a probable cause of death. After looking at the cases from this stand-point, can any of the three cases be said to have been a *bona fide* case of "ether death"?

The cases of death from ether which were collated by Dawson* are eighteen in number. Of these, Dawson rejects nine, while Roberts accepts three cases which Dawson rejects, and rejects one which Dawson accepts.

* British Medical Journal, vol. i., 1878.

In the following review of these cases, no notice will be taken of those which are rejected by both Dawson and Roberts, or of those cases in which any anæsthetic save ether was used. The number attached to each case is that which is assigned it by Dawson in the original article.†

Case IV.—Male, æt. 14, of strumous habit. While ether was being administered, and *after* the face had become intensely red, it was announced that the pulse was failing, and the ether was withdrawn and the operation concluded without any attempt to resuscitate the lad. Shortly afterwards the pulse became imperceptible and the boy died. The ether was administered in such a manner as to exclude air entirely.

Bigelow‡ intimates his belief that if proper treatment had been adopted the lad would not have died.

Case VIII.—A patient at the Homœopathic Hospital, New York, was etherized, and during etherization the pulse, which was watched very carefully, failed, and the man's face suddenly became blue.

Ether does not affect the respiratory centres suddenly, and the chances are that had the respirations been observed as carefully as the pulse, the man would not have died.

Case IX.—Male, æt. 74, inhaled one-half pound of ether and commenced coughing; his face became livid. The ether was withdrawn and the operation finished.

Here the charge of negligence will again hold, for no attempt at resuscitation was made.

Case X.—Female, æt. 45, was operated upon for cancer of the uterus. After anæsthesia had been produced, the ether was administered by a female attendant, and when the physicians again noticed the patient's condition she was pulseless and breathless. At the post-mortem the lungs were found gorged with blood.

Is it not possible that an embolus may have been carried from the uterine veins to the pulmonary artery and thus have produced the pulmonary engorgement? Or does the charge of improper administration have any force?

**Case XIII.*—After recovering from ether, the woman died. There were stertorous breathing and coma. The symptoms did not present themselves immediately. At the autopsy, cerebral hemorrhage was found.

If ether had caused the hemorrhage, it would have occurred when the cerebral and cardiac excitement were greatest.

† Cases marked * are rejected by Dawson and accepted by Roberts.

‡ British Medical Journal, vol. ii., 1873.

**Case XIV.*—Male, æt. 69, operated upon for strangulated hernia. Clover's inhaler used, and the man breathed only expired air and ether for some time. He struggled violently, his lips became blue, and the pulse failed. Respiration continued for some time after the pulse became imperceptible. At the post-mortem, the heart and lungs were found diseased.

This death is just the opposite of what "ether death" should be, and is very like death from collapse; and in what cases would death from collapse occur if not in cases of strangulated hernia?

Case XVII.—Male. After recovering from ether the patient was carried through an open court-yard about fifty yards in length. Death occurred in one and one-half hours.

The symptoms and manner of death are very much like those of Dr. Roberts's third case. The lungs were œdematous. Nothing is said as to the condition of the kidneys.

Case XVIII.—Female, æt. 45. Cancer of breast. After a few inspirations the face became turgid, and death ensued fifteen minutes later. At the autopsy, the lungs were found to be filled with cancerous deposits. The ether was administered from a leather cone with two openings in it. Death was from asphyxia, easily produced because of the condition of the lungs and facilitated by the use of an impervious cone.

The report of the case quoted by Dr. Roberts in his summing up shows that twenty inches of intestine were strangulated, that this intestine was becoming gangrenous, and that peritonitis had set in. Was there not sufficient cause for death in this instance? And would not death have followed whether the anæsthetic had been used or not?

In the original report of Mr. Hartley's case* a probable cause of death is given.

As was mentioned by Dr. Roberts, there is an account by Mr. Burton and Dr. Jacobs† of the deaths from ether which have been reported in the journals of Great Britain. The writers state that in almost every case some other cause than the effects of ether can be assigned as the reason for the death. The article states that since 1870 there have been reported one hundred and twenty deaths from chloroform and eleven deaths attributed to ether.

Many of the cases recorded here are reported by Dawson, and the greater number of those not given by him and mentioned by these writers are reviewed in this article.

In Dr. Dandridge's case‡ the patient had suffered for a long time with an abscess of the thigh which opened in the popliteal space. The woman was very anæmic in consequence of the drain on her system, and also from almost constant vomiting. The woman had been etherized several times before, when she was apparently in a much more enfeebled condition. The administration was proceeding very satisfactorily until, suddenly, the breathing stopped and she became pulseless. She was partially revived by appropriate treatment, but respiration gradually failed.

Here, also, because of the time elapsing from the time of inhalation until death occurred, "ether death" is improbable. There is also the possibility in this case of an embolus having been lodged either in the brain or in the lungs. The head of the patient was lowered to prevent anæmia of the brain. One and one-half pints of brandy were given her per rectum and by hypodermic injection. The amount of alcohol was sufficient to produce paralysis of the cerebrum. It is well known that large doses of alcohol decrease the force of the heart by direct action on the heart-muscle, and lessen the frequency by stimulation of the inhibitory apparatus at first, but finally the frequency is increased by paralysis of the inhibitory nerves.

In cases of congestion of the lungs or other diseases which interfere with respiration, we support the patient in a semi-recumbent position. Why, then, should this woman have had her head lowered? According to the report of the case, the danger was first exhibited by the respiratory system. Why should congestion of the lungs caused by ether be treated in a less rational manner?

I have not had access to the other cases quoted by Dr. Roberts.

After looking at the cases from this stand-point, can any one of them be said to be a genuine case of "ether death"?

THE twenty-fifth anniversary of Dr. Rudolf Virchow's appointment as Professor in the University of Berlin is to be celebrated on October 13.

THE degree of LL.D. was conferred by Yale College, at its late commencement, upon Prof. Austin Flint, of New York.

ILLUSTRATIONS OF THE USE OF LARGE HYPODERMICS OF MORPHINE AND THE DANGERS ATTENDING THEM.

BY E. T. BLACKWELL, M.D.

HYPODERMIC medication, in furnishing a means of speedy relief from pain, has made the average sufferer impatient of the delay necessary to a correct elucidation of its cause and clamorous for the application of a remedy; the bystanders also, especially in cases of abnormal nervous manifestations, often joining in the demand for instant succor, and bringing a pressure upon the physician that may cause him to hasten and obscure the final diagnosis. If the practitioner is a routinist, he is apt to resort to hypodermic application in cases where great pain might be looked for; but where, from shock or other cause, but little is felt, the unreflective or impulsive man does not appreciate, till too late, that the remedy, when placed within the integument, is to a very considerable extent beyond his control.

The following cases, in which it was necessary to push the administration of morphine to the extreme limits of safety, and in which, though great caution was observed, a perilous condition was developed, are recorded for the benefit of any who may be obliged to use medicines in this prompt and efficient but hazardous way.

Case I.—Mrs. E. A. W., brunette, 30 years of age, commenced to menstruate previous to her twelfth year, the flow being always profuse and attended by very severe headaches and confinement to bed for two or three days. She was subject to sick-headache when exposed to unusual excitement or fatigue. Her mother had a like experience.

Mrs. W.'s second pregnancy occurred in the spring of 1877. Near the end of her term she was taken with excessive tightness of the chest and a feeling of suffocation, for which she was bled, with complete relief. On January 11, 1878, after a rather easy labor of a few hours' duration, she was safely delivered of twins. Notwithstanding the satisfactory conclusion of the process and the exemption from loss of blood, she had a light swoon soon after, but was left comfortable and composed. A general peritonitis succeeded almost immediately, her convalescence from which occurred about February 10.

One day, in the week following, she had a succession of calls, followed by extreme nervousness and a uterine hemorrhage. For this she received a hypodermic injection of morphine, with Hance's extract of ergot. During the month of March each infant in succession had severe pneumonia. From the constant mental and physical strain, she had, on April 13, a headache that seemed overwhelming in its intensity. The acutest distress appeared to be in the superior convolutions of the brain. She clutched her hair desperately, at one time bringing away a handful that was long retained in her grasp. She vomited occasionally, and the nausea was great. A hypodermic of morphine, estimated at a half-grain, was gradually administered, completely relieving the head and checking the vomiting, though the nausea continued for some time.

On May 6, there was a recurrence of the seizure, extraordinary in its violence, compelling resort to the hypodermic of morphia, which was supplemented by chloral and guarana. On the 11th of June, the 21st of July, and the 7th of August there were recurrences, connected with the sickness and death of the infants from cholera infantum. These attacks were treated as before. The rest of the year, her cares being less, there was a respite from these monthly scourgings; but on January 26, 1879, there was an outbreak, which was subdued in the usual way, as was also the case April 6. During the summer months the suffering at the periods was not so extreme, and was alleviated by chloral and inhalations of ether and chloroform, administered by the husband, while the system was strengthened by constant use of syr. ferri bromidi. A thorough trial was made, during the several menstrual periods, of the fluid extract of ergot. In the autumn there is a history of monthly recurrences of the agony in the head and the accustomed resort to the use of morphia. Up to the last of this year, the amount of the medicine inserted at each period did not probably exceed a half-grain, which was administered very gradually and cautiously, the time occupied being from one to two hours. The beginning of the year 1880 was signalized by an outbreak on January 18, to be succeeded by a most terrific one on February 16. Relief was attempted by the inhalation of equal parts of stronger ether and chloroform, but, notwithstanding the pulse was nearly extinguished by their intense action on the heart, the pain abated but little. A hypodermic of morphia was now given, with a few drops of fluid extract of belladonna, which was followed, not long after, by symptoms of opium-poisoning. An additional amount of belladonna was given subcutaneously, and elixir of strychnia and whisky by the mouth, the unfavorable effects passing off in the course of two or three hours. Deeming that the menorrhagia had produced anæmia, the taking of bromide of iron was insisted on during all the intervals. The successive periods were variously passed, sometimes being endured through the inhalation of anæsthetics, or by an occasional dose of morphine by the

mouth. On the 27th of August the headache reached its acme at 9 P.M., when a half-grain of morphine was given beneath the tissues; in the course of an hour another half-grain was given. Leaving her towards eleven o'clock, not fully relieved, her husband resumed the exhibition of the chloroform mixture, which had also been used previous to my visit. While breathing this she became unconscious, a leaden blueness overspreading the face and hands, from imperfect respiration. When five drops of extract of belladonna had been exhibited subcutaneously, the blueness disappeared. A hypodermic of two grains morphia, with five drops belladonna extract, on the 30th of September and 20th of December respectively, closed the year. The new was greeted with a fresh attack, resulting from the fatigue attending the holiday hospitalities. From three to five o'clock P.M. of January 1 she received beneath the cutis two grains morphia and twelve drops extract of belladonna, which were to be supplemented, as required, by five grains chloral and ten minims elixir valerianate of zinc. Hitherto the quantity of morphine exhibited was estimated. I now resolved that I would ascertain the exact amount used by weight. An opportunity occurred on January 24, when she received morphine and belladonna in the amounts and at the intervals here indicated. The salt used was the acetate, an extemporaneous solution being made by the addition of vinegar.

7.10 P.M.—	Morphiæ acetas,	gr. ½; ext. belladon. fl.,	gtt. ij
7.35 P.M.—	do.,	gr. ½; " " "	gtt. ij
7.45 P.M.—	do.,	gr. ½; " " "	gtt. ij
8 P.M.—	do.,	gr. ½; " " "	gtt. ij
8.25 P.M.—	do.,	gr. ½ approx. " "	——
	Amount,	2½ grs.	gtt. viij

The patient at this time was having a flow, attended with pain in the back and occasional small clots; and, as she had missed a menstrual period, it is possible that an impregnated ovum passed away. The pain and clots continuing, on the next day she received medication as follows:

4.30 P.M.—	Morph. acet.	hypodermically,	gr. i
5 P.M.—	"	" "	gr. ½
5.10 P.M.—	"	" "	gr. ½
5.35 P.M.—	"	" "	gr. ½
			gr. 2½;

with 3 grains Hance's extract of ergot.

January 26.—The patient failed to sleep, complaining of pain and itching, from the last of which she often suffers. I determined to test the effect of atropia, giving the officinal solution of the sulphate, as follows:

10.25 A.M.—	Liq. atropiæ sulph., hypodermically	gtt. ij
10.35 A.M.—	Liq. atropiæ sulph., hypodermically	gtt. ij
10.45 A.M.—	Liq. atropiæ sulph., hypodermically	gtt. ij
10.55 A.M.—	Liq. atropiæ sulph., hypodermically	gtt. ij,

equal to one-thirtieth grain.

No result followed, the pupil being unmoved; neither was the pupil contracted to any great degree when most under the influence of the morphine. At the evening visit recourse was again had to morphine.

7.30 P.M.—	Morph. acet. (by weight),		gr. i
7.45 P.M.—	"	" "	gr. i
8.10 P.M.—	"	" "	gr. i
			gr. iii,

as appears by my notes, though my recollection is that there was another injection of one grain.

January 27, 7 P.M.—Mrs. W. has slept scarcely any during the last three days,—an hour, perhaps, on the evening of the 25th. I prescribed for her as follows:

℞ Chloralis hydrati, ℥ij;
Ext. glycyrrhizæ fl., ℥ss;
Aq., ℥iiss.—M.

S.—A teaspoonful to be taken every hour, till relieved.

That night the patient slept reasonably, but on the following night, when the nurse doubled the dose, she became delirious.

Case II.—Mrs. M., aged 42, became pregnant near the close of the year 1879, and was immediately affected with great nausea and vomiting, which were very persistent, extending in varying degrees during the greater part of her term of gestation, reducing greatly her strength and compelling constant confinement in bed. She was seized with spurious pains on August 31, for which, at 7.30 P.M., she received a hypodermic of morphiæ acetas. On September 1 she had recurrence of the pains, and from 6 P.M. to 10 P.M. she received one and a half grains, with eight drops fluid extract of belladonna. September 2, from 4 A.M. to 6 A.M. she received two grains, with belladonna extract. September 3, at 4 A.M., she was taken with genuine labor-pains, the agony of which was tempered by anæsthetics, and the efficiency of which was enhanced by ergot. The babe, weighing twelve pounds, was born, lifeless, at 8 A.M. In the evening she was complaining of pain about the loins, and of nausea and fever, the pulse being 106. From 7 P.M. to 9 P.M. she received a hypodermic of morphine, and was ordered the following medicine:

℞ Potassii citratis, ℥j;
Acid. hydrocyan. dil., ♏xx;
Tinct. opii deodorat., ℥j;
Aq. menth. pip., ℥iij.—M.

S.—A teaspoonful to be taken every two hours. A grain of calomel was also to be taken every two hours till the bowels should respond.

September 4, 8 A.M.—The patient has slept none during the night, the pain in the side remaining unabated. Pulse, 112 to 120.

From 8.30 A.M. to 9.30 A.M. she received

one and one-quarter grains of morphine, with five drops of belladonna extract.

September 5.—The patient has rested fairly, enjoying many short periods of sleep. She has had one free and two or three smaller evacuations of the bowels. She reports having had a "weak spell." Her pulse marks 112, but is easily excited to 120. Calomel withdrawn.

At 7 P.M. she was vomiting greenish water, and the bowels had been several times moved. Ordered—

℞ Sodii bicarb., gr. xxiv;
Ac. hydrocyan. dil., ℥v;
Aq. creasoti, ʒi;
Glycerinæ, ʒiij;
Aq. cinnamomi, ʒiiss.—M.

S.—A teaspoonful every half-hour.

September 6.—The patient rested perhaps for three hours. Pulse 90. Ordered—

℞ Bismuthi subcarb., ʒij;
Aq. creasoti, ʒi;
Glycerinæ, ʒiij;
Tinct. opii, ʒss;
Ext. krameriæ fl., ʒss;
Aq., ʒijss.—M.

S.—A teaspoonful every hour.

During the 7th, 8th, and 9th the patient's condition appeared good, the pulse varying from 85 to 90 per minute. She took moderately of quinidiæ sulph. On the 10th, at my morning visit, she complained of pain and stiffness of the jaws, inability to open the mouth, and difficulty of swallowing,—of trismus, in fact. She was ordered chloroform liniment, the former medicine to be continued with pills of opium. At 11 P.M. I was summoned, the patient suffering agonizing pains at the insertion of the deltoid muscle. In the course of two hours she received subcutaneously one and a half grains of morphine.

September 11, at 10 A.M., her pulse was very quick, reaching 132 per minute whenever she was raised to the sitting posture. Ordered—

℞ Chloral. hydrat.,
Salicin., āā ʒss;
Liq. acidi hydrobromici, ʒvj;
Ext. glycyrrhizæ fl., ʒij;
Aq., ʒij.—M.

S.—A teaspoonful to be taken every three hours.

At 4 P.M. the pain returned in such an agony about the nucha and the lower part of the back that the sufferer demanded instant relief, utterly refusing to allow any investigation of the affected parts. The time occupied in the insertion of the remedy was two hours, the amount of morphine used being estimated at two and a half grains. At 9 P.M. her pulse was very rapid; the respirations also were shallow and quick. Death occurred about 11 P.M.

Case III.—Jesse M., a healthy young man, who had recently left the farm to run a button-hole machine in a clothing-factory, after a few days of malaise and defective appetite, during which he worked extra hours, passing a whole night closely engaged, was taken, at 3 P.M., August 27, with violent convulsions, attended with frothing at the mouth and grinding of the teeth. In the course of three hours, during which he took, by inhalation, two ounces of chloroform and some stronger ether, he had many fits of extraordinary violence.

At 6 P.M. he received subcutaneously one grain acetate of morphia, which quelled the violent manifestations. At 10.30 P.M. a half-grain additional was given. At midnight I was called, the messenger saying that the breathing was peculiar. I found his respiration snoring and only six per minute. Gave a hypodermic of three drops ext. belladonna. In an hour the respiration arose to between seven and eight per minute, after which he rested well till morning. The treatment was continued a few days on general principles, there being no return of the paroxysms.

My experience would lead me to be very cautious in repeating hypodermic injections of morphine after the patient begins to come under its influence, and either to await its full development or to return subsequently, if fear is felt as to its sufficiency, and deepen the effect if then thought necessary.

In the *Medical and Surgical Reporter* for September 11, 1880, is an abstract from the *Practitioner* of June, 1880, of "Cases Illustrative of the Advantages of using Morphia very freely," the relation being such as to convey to the mind of the reader a belief in the safety of enormous doses given hypodermically. Three grains were gradually injected in a case of delirium tremens; two days subsequently two grains were given, without effect; and two days later five grains of acetate of morphia were given, apparently without interval. The outcome was good; and this bright side of success is presented for our admiration, while the darker side of danger remains in shadow. The result is an overweening confidence on the part of the incautious and inexperienced. No one, whatever his skill, can afford to exhibit these heroic doses without bearing constantly in mind the risk he incurs, and the possibility of passing the line of safety and causing the death of the patient,—an accident that has so frequently befallen that a dread of the method exists among the people, leading them to oppose it in many instances in which it seems to be the only available procedure.

A CASE OF POISONING BY ONE OUNCE OF LAUDANUM—USE OF ATROPIA—RECOVERY.

BY S. J. RADCLIFFE, A.M., M.D.,
Washington, D.C.

AT about 9.30 P.M. of May 4 last I was called to see V. T., a young woman about 23 years of age, of fine physique and appearance,—one of the *demi-monde* of the better class,—who I was informed had taken, about half an hour or more previously, a small vialful of laudanum with suicidal intention,—the messenger, as I discovered afterwards, happening to be her lover, with whom she had had, no doubt, some misunderstanding, and who was evidently much agitated.

I found her lying in bed *en déshabille*, somewhat sleepy-looking, indifferent to my entrance, careless to answer questions, apathetic as to her condition. She admitted she had taken the vial of laudanum (pointing to an empty ounce vial on the wash-stand near), and with the intention of taking her life. She was angry that I came in, and wished that I would let her alone and let her die, as she did not want to live. She would give no reason for her rash act further than is intimated above.

The vial contained but a few drops of the liquid, which upon examination proved beyond doubt to be tincture of opium. She had taken the label off, she said, to avoid detection as to where or when it was bought or for what purpose. I traced the purchase of it, however, to a neighboring drug-store, and found the only difference in her description was—as recorded on the druggist's poison-book—that she had given Fourteenth for Thirteenth Street, and had changed one figure in the number of the house, which was done of course intentionally and evidently with the purpose of deceiving.

At first she resisted stubbornly all efforts made to examine her; but, finding I was positive about it, she submitted and allowed me to proceed, until I was informed of her real condition.

I found her pulse full and strong, beating about 64 per minute; breathing slow, easy, and without special note; was disposed to close her eyes and sleep; pupils but slightly affected; and altogether she was in a condition denoting that peculiar quietude and *abandon* preceding narcotism.

As I was satisfied she had taken the laudanum, I told her she must not lie there and die without an effort being made to save her, and I took her by the arm and pulled her out of bed and placed her on a chair near by.

I had in my pocket forty grains of sulphate of zinc in two powders, one of which I administered at once and the other in ten minutes after, without any effect. I then had warm water and mustard brought, and gave her large draughts of mustard-water, and induced her to tickle her throat and thrust her finger down as far as she could, when she threw up a mouthful or two of fluid smelling strongly of opium.

As this opium odor indicated that it had not all been absorbed, I then sent for one drachm more of sulphate of zinc, in three parts, and administered it, one powder after another, at intervals of ten minutes, without producing free emesis. Only a little fluid was vomited, and then only as it was assisted by warm mustard-water.

Her condition was now becoming alarming, and it was with great difficulty we could keep her awake or on her feet. If she sat down on a chair, her head would fall over on her breast or on her shoulder, and she would breathe heavily and seem oblivious to everything around; and if we attempted to walk her, she would stumble and fall, and had to be held up by main force. She was not conscious enough to control her actions or movements in the least, and we had to abandon walking for a while.

Fortunately, I had with me a solution of sulphate of atropia (one grain to the ounce of water), which I had brought with me from my office to use in case of emergency. I injected now ten drops hypodermically, representing $\frac{1}{48}$ of a grain of the atropia, and returned home for my stomach-pump, hoping still to make it of use in relieving the stomach of any remains of the drug, leaving instructions to keep her awake if it could be, and up and moving about as much as possible; to continue dousing her face and head with cold water, flapping the towel in her face and slapping her cheeks if necessary.

It was now nearly or quite twelve o'clock,—nearly two hours and a half since I first saw her; and her condition seemed desperate indeed. She had not responded to treatment so far; absorption had gone on so rapidly that she was pretty well under

the influence of the narcotic,—indeed, might be said to be completely narcotized. The insensibility of the stomach was such that it could not be acted on sufficiently; it had been relieved of only a part of its contents, and I had but little hopes of doing much more, except what might be expected from the atropia. With a view of putting this remedy to a proper test, I now gave her another hypodermic injection of sulphate of atropia ($\frac{1}{48}$ of a grain), and with the assistance of two persons in the room I introduced without trouble the stomach-tube, and after a few motions of the piston of the pump, in order to introduce clear water, as if the atropia was beginning to show its action, spasmodic contraction of the stomach took place, and, forcing out the tube, quite half a gallon of fluid with but little odor of opium followed; and the emesis continued in two or three straining efforts, emptying the stomach of the greater part of its contents. I introduced the stomach-tube again, and pretty thoroughly washed out the stomach, until the washings became unmixed and nearly clear and without odor. This had the effect of arousing her somewhat, and she yielded to further treatment without objection; so in a little while—say towards one o'cloçk A.M.—she began to show signs of consciousness and replied to some questions asked her. Her pulse was weaker, a little thready and irregular and quicker, and respiration had also quickened, and the surface-temperature had much diminished. If she attempted to open her eyes, the light would dazzle them, so that she would quickly close them to shut out the glare, or would look at an object sideways or close one eye and look at it at different angles, and seemed more like one under the influence of atropia with dilated pupils than like a person under the influence of opium. She could scarcely look at the gaslight, though her pupils were not much dilated above a normal condition. We walked her up and down the room and watched her with increasing interest, and the first good evidence of returning consciousness that she exhibited was that she asked repeatedly what made her itch all over so. This itching, she said, was most intolerable, and seemed to harass her beyond measure, and she asked to be rubbed and scratched with a metallic brush she picked up, which she used freely herself about her arms and shoulders. It seemed to annoy her exceedingly; and the more conscious she became, the more distressing it seemed to be to her. There was quite an efflorescence over most of the body, quite perceptible especially over the neck and arms, and from this condition the unfavorable symptoms gradually subsided and the progress of the case was entirely satisfactory. This efflorescence appeared to bring warmth to the skin and brilliancy to the complexion and heightened the activity of the patient, as she moved with steadier gait and conversed with more vivacity, though still drowsy to a great degree. I stayed with her until 1.30 A.M., when I considered her out of danger, and left instructions to watch her for at least an hour before allowing her to lie down, and directed that some one should watch her until daylight.

I saw her again at 9 A.M., and found her quite recovered and in fair condition under the circumstances. Some nausea remained, and some fulness of the head, for which I directed a small cup or two of strong coffee to be taken during the day. At 9 P.M. her condition was still good and required no further treatment.

Note.—With a view to contribute something to the literature of the antagonism between opium and atropia, I report the above case. It is true the quantity taken was not so large as has been reported by others, yet the toxic effect was such as to cause great anxiety as to the results, and the treatment proved that its degree was not overestimated.

There is no rule yet observed to gauge the quantity of an agent necessary to produce toxic action or make a lethal dose, as what might prove a lethal dose to one might not prove such to others. It seems to depend entirely upon idiosyncrasy or susceptibility.

Bartholow says it is a very difficult matter to determine the amount of poison necessary to constitute a lethal dose, for comparatively small doses of opium and laudanum have sometimes proved fatal, according to Taylor and other reliable authorities; and, on the other hand, no less than eight ounces of laudanum have been taken without injury;* and therefore it is nothing against this case that the amount of laudanum taken was only one ounce. The condition of the pupils,

* Cartwright Lectures.

the pulse, the respiration, the impairment of muscular power, the stupor, all pointed to the toxic action of the drug.

The case was seen somewhere within an hour after the laudanum was taken, as reported to me, before, probably, all of it was absorbed from the stomach,—time, however, sufficient for it to more than begin its action upon the heart and nervous centres; but the treatment was begun actively and was kept up promptly without loss of time until the patient was out of danger.

From the continuously active treatment employed and persevered in throughout, at no time was the patient profoundly narcotized, nor did marked coma or stertor decidedly supervene, though there was deep stupor, and grave apprehensions existed as to its tendency towards coma; yet it might and probably would have been the case if it had been left undisturbed and without treatment for any length of time longer, for absorption was continuous, and in about two hours, in spite of treatment, the patient was in great danger, and was aroused only with the greatest difficulty.

While the case may not, however, be considered a typical one of opium-poisoning, when the case was seen first *in extremis*, and in which atropia was used only and as a last resort, upon whose perfect and complete antagonism the proof of its real therapeutic action could be based, yet it was one in a marked degree offering all the symptoms of the gradual but continued action of the drug; and its favorable issue seemed so much to be the result of a right line of treatment that the belief is warranted that atropia aided very greatly, or was a prominent factor, in bringing about that result, although a source of fallacy, as Bartholow says, in estimating the validity of the antagonism in these cases is the fact that in the greater number of them various approved agents, such as emetics, the stomach-pump, faradization, ambulation, flagellation, etc., were made use of in addition to the antagonist, most of which were used in this case.

The quantity of atropia used was about $\frac{1}{24}$ of a grain in all, and the antagonism seemed to be well balanced and sufficient. The slight efflorescence and the state of the pupils when the patient became conscious indicated that there was rather a preponderance of the antagonist; but the more or less stupid condition in which she remained for several hours after, and the want of more manifest symptoms, refuted this idea. Bartholow says, "In some actual trials I have found that $\frac{1}{20}$ of a grain of atropia is about equal to one grain of morphia in toxic power," which is above the quantity I employed in this case,—nearly double; and Phillips observes that in certain patients poisoned by opium an intense irritation of the skin, with intolerable itching, and sometimes even the production of a sudaminous rash, has been observed,—these effects resulting both from the external and from the internal use of opium.*

1211 F St., N.W., Washington, D.C.

A CASE OF ILIAC ABSCESS SIMULATING COXALGIA.

BY CHARLES A. CURRIE, M.D.,
Resident Surgeon to the Episcopal Hospital.

JOSEPH G., aged 9, was admitted into the hospital on May 5, 1881, with the following history.

Two weeks before admission he had a fall from a pile of lumber, dragging after him a board, which fell across his abdomen, striking with most force on his left side. He was able to rise and go home, not mentioning the circumstance to his parents. The following week he complained of a slight pain in his left side in the region of the iliac fossa, which was increased by any effort at walking, causing him to limp with the left leg. He was shortly afterwards brought to the hospital for what his parents supposed to be hip-joint disease, and carefully examined by Dr. Wm. S. Forbes, the attending surgeon, who found him suffering from the following symptoms. When lying on his back, the left thigh became strongly flexed on the abdomen, which, being straightened as far as possible, caused a very marked anterior curvature of the lumbar vertebræ; the foot was everted; pressure over the site of the injury caused a good deal of pain, but no external evidences of the injury were noticeable. From this time he evinced considerable febrile disturbance, the temperature ranging from 99° in the morning to 103° and 104° in the evening. There was no posterior angular projection of the vertebræ, nor tenderness over them,

* Materia Medica and Therapeutics.

as would exist in a case of Pott's disease. The affection was at this time thought by Dr. Forbes to be intra-abdominal.

On the morning of June 3, while dressing the case, I noticed a slight redness about an inch above Poupart's ligament and towards its outer third, which was very tender to the touch, and to which I drew the attention of Dr. C. T. Hunter, the visiting surgeon at that time. The next morning it showed distinct signs of fluctuation and the general characteristics of an acute abscess, which the doctor then opened, and immediately there welled out a large quantity of healthy pus: it contained no necrosed bone. On passing the finger into the opening thus made, it went directly into the cavity of the abscess, which was found to rest on the venter of the ilium. It was possible to almost completely encircle the psoas muscle; and further examination showed that the abscess had no communication with the sheath of that muscle. A drainage-tube was then inserted and the abscess poulticed. The temperature fell almost to normal, and the lad's general condition markedly improved. A week later the tube was withdrawn and the edges of the sinus allowed to granulate, which began to close up; and on July 8 he was discharged recovered.

The case was peculiar on account of its presenting symptoms similar to those of coxalgia,—viz., the deformity consisted in the thigh being flexed on the abdomen, the leg on the thigh, and the foot being everted. When standing on his feet, the weight of the body was borne entirely by the sound limb, and the fold of the nates was entirely obliterated on the affected side. Opposed to these symptoms were pain confined to the iliac region almost entirely; no tenderness on pressure, either over the anterior face of the hip-joint or between the great trochanter and the tuberosity of the ischium. Another point which militated against its being a case of coxalgia was the fact that the three points—viz., the tuberosity of the ischium, great trochanter, and the anterior superior spinous process of the ilium—were all in perfect line. Psoas abscess was ruled out from there being no history of disease of the vertebræ, no tenderness in the lumbar region, and no curvature; so that it proved to be simply a case of abscess of the venter of the ilium due to a traumatic cause, which in time recovered perfectly.

NOTES OF HOSPITAL PRACTICE.

UNIVERSITY HOSPITAL.

CLINICAL SERVICE OF JOHN ASHHURST, JR., M.D., PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF PENNSYLVANIA.

Reported by Guy Hinsdale, M.D., May 14, 1881.

HYDROCELE.

THIS man has the history of a tumor in the scrotum, of long standing. It has been tapped six times, and he is now anxious for radical treatment. For this I prefer the injection of the pure tincture of iodine, which produces a certain amount of irritation of the sac,—enough to prevent a reproduction of the fluid.

Some surgeons suppose that to prevent the effusion and effect a radical cure it is necessary to produce adhesion of the opposing surfaces of the sac. Others, including Mr. Erichsen, believe, on the contrary, that after this mode of treatment adhesion does not occur. My own opinion is that a cure may be effected in either way; while adhesion does undoubtedly occur in some cases, it is by no means invariable. In some instances no adhesions have been found on dissection, and yet the hydrocele had been cured. There must have been some change in the tunica vaginalis itself.

The older pathologists would have said that, in a hydrocele, the true balance between the exhalants and the absorbents was destroyed,—that, in such a case, exhalation was greater than absorption. Their treatment would have been to endeavor to restore the proper balance.

Observe the shape of the tumor. It is pyriform,—larger above than below. This sac is not so tense as we sometimes see.

It is important to make the diagnosis from hernia. The neck of a hernia would pass up within the inguinal canal, but, as you see, this tumor can be entirely isolated in the scrotum. Viewed by transmitted light, hernia would be opaque; the hydrocele, translucent.

Before injecting the iodine we will endeavor to empty the sac as completely as possible. Grasping the hydrocele with my left hand, so as to make the skin tense, and knowing that the testicle is at the back part, avoiding the veins, I make a quick thrust with the trocar and canula. The instrument should at first be pushed directly backwards, and then the handle depressed, so as to avoid wounding the tes-

ticle. On withdrawing the trocar a clear liquid flows out.

The fluid of a hydrocele may coagulate spontaneously. I have seen one or two such instances. It is always highly albuminous. The spontaneous coagulability is, I believe, only met with at second or later tappings, and is probably the result of previous inflammatory action.

When the sac is completely emptied, inject pure tincture of iodine, one to three drachms, according to the size of the sac. I will use three drachms here. The iodine is now injected, and as I withdraw the canula I guard the opening so as to prevent the escape of the fluid from the sac, and allow it to remain in.

The former plan was to use a large quantity of a diluted tincture of iodine or a solution of iodine and iodide of potassium, and to allow the fluid to flow out again through the canula before the latter was withdrawn.

Prof. Syme's plan, which I employ, was to use a small quantity (f℥j–iij) of the pure tincture of iodine and allow it to remain in the sac.

By a little manipulation we bring the fluid in contact with all parts. In a day or two the swelling returns: in fact, it becomes almost as large as before the operation; but it then gradually subsides until the cure is completed.

Convalescence is hastened by strapping the testicle as we would in orchitis. The patient should be confined to his bed, or at least a lounge, for two or three days. Strapping alone has been used to effect a radical cure after drawing off the liquid.

Another method is that of introducing a seton. Sir James Simpson used silver wire for this purpose; but the silver does not excite a sufficient amount of inflammation. The disadvantage of the silk thread, on the other hand, is that suppuration is apt to follow.

The success of the treatment by injection is well established. Prof. Syme declared that he had never met with a failure. I have myself, however, sometimes had to repeat the operation.

NÆVOID SARCOMA OF THE LEG.

This patient presents a tumor upon the inner side of the leg just above the ankle. She has had from birth a small discolored spot on the leg,—a nævoid condition of the skin. Within a short time this growth, which has been rapidly enlarging, has begun to ulcerate, slough, and bleed. It is, I believe, a sarcoma associated with a nævoid growth. It was a nævus first,—a teleangiectasis,—followed by the development of sarcomatous tissue around and beneath. It is evidently not a pure nævus, and, on the other hand, we rarely have a pure sarcoma bleed so profusely as this has done.

There may be some difficulty in closing the wound, as the skin is pretty widely involved. The edges of the growth are indurated, red, and infiltrated. When sarcoma affects the soft tissues it is often an infiltrating disease, but not so markedly as carcinoma. We will close the wound as well as possible with hare-lip pins and press the parts into apposition. The central portion of the wound may have to heal by granulation. The operation will present no difficulty, and, I think, will promise a good result. The growth is freely movable and does not involve either bone or tendon, so that there will be no risk of impairing the usefulness of the limb.

You observe I make the lower incision first, going up in the sound skin above, and I now separate the tumor by tearing, not by cutting. The vascular character of the disease is shown by the very free bleeding as the parts are divided, the hemorrhage, however, ceasing as soon as the growth is removed. A simple angeioma would show a congeries of vessels with hardly any other tissue; but portions of this growth are, as you observe, quite dense and firm.

We will paint this wound with a weak solution of the chloride of zinc (gr. xv–f℥j), not strong enough to produce sloughing. The use of this substance was strongly praised by the late Mr. De Morgan after all operations. He used stronger solutions,—twenty, thirty, and even forty grains to the fluidounce.

We here use four pins, the parts being moulded into position, and, though we shall not get primary union, yet, when the pins are taken out, there will be less surface to heal by granulation. I place an interrupted stitch at each end, and the wound is supported by strips of adhesive plaster placed between the pins and in a spiral direction to prevent the possibility of exerting undue circular compression. I cut off the points of the pins. Over this we place some oiled lint, and, as we will

not disturb the dressing for forty-eight hours, we will cover this with oiled silk; waxed paper has hardly stability enough to last so long a time. Now place a bunch of oakum over the side of the leg, as a pad, and apply a roller from the foot nearly to the knee.

SEBACEOUS CYST OF THE FACE.

This man has a tumor just below the right eye. Its nature seems to be cystic. The skin is adherent from the result of irritation and inflammatory action. It is rather hard to distinguish between a cyst with very hard, firm walls and a fibrous tumor which is not cystic.

We hasten anæsthesia by compressing the chest as the patient breathes out. By doing so we expel some of the residual air from the patient's lungs and compel him to breathe more of the anæsthetic vapor. In giving ether, watch the color of the patient and the respirations; if you use chloroform you must also watch the pulse. There is no danger in giving ether while the respiration is full and the color good. The patient may, however, be endangered from fluids and vomited food accumulating in the back part of the mouth and occluding the air-passages.

The incision is made in a curved direction, to make the cicatrix as little apparent as possible. There is no suspicion of malignant disease, and it is not necessary to remove any skin; the cutaneous adhesion is simply due to inflammatory action. The contents are atheromatous and sebaceous matter.

These growths are classified by Paget as cutaneous, proliferous cysts. The cyst-wall becomes thickened by successive layers of epidermis which are pushed inward, forming concentric laminæ. If any portion of the wall should remain after the operation, there would be a chance that the cyst would return.

When we loosen the adherent skin from the surface of the cyst, we can often turn it out with the handle of the knife. The most difficult cases to deal with are those whose seat is near the external angle of the eye, where they are always closely adherent.

The wound is closed by silver sutures, and the parts further supported with strips of gauze painted with collodion, so that, as far as possible, union by first intention may be secured. The wound is then covered with lint spread with zinc ointment and strips of adhesive plaster.

TRANSLATIONS.

APHTHOUS VULVITIS AND GANGRENE IN YOUNG CHILDREN.—Prof. Parrot (*Revue de Médecine*, 1881, p. 177) says that this form of disease is not necessarily confined to the vulva, but may also appear about the perineum, around the anus, in the genito-crural folds, and in the groins. It is by far the most frequently met with in the vulva, however.

The aspect of the affection varies according to its stage. At the beginning it consists of small hemispherical patches, whitish or grayish-white in color and somewhat elevated even when excavated at the centre. Their diameter varies from one to three or four millimetres. They are formed in the same way as aphthæ of the mouth, and show little or no colored areola. In some cases the epidermis is destroyed and the vesicles rest upon a red and moist surface. The number of the lesions is variable. Sometimes there are only two or three; occasionally they are confluent; but commonly from six to twelve are encountered in a group or isolated.

Such is the first stage of the eruption; but after the lesions have existed for two or three days the disease commonly assumes a somewhat different aspect. In addition to the lesions above described, roundish, cup-shaped ulcers may be descried here and there, with grayish or yellowish base surrounded by a red areola and very often attended by pruritus, which may show itself among the first symptoms and sometimes assumes marked proportions, causing constant rubbing on the part of the little patients. Energetic means must be taken in order to prevent such scratching as shall result in wounds of the parts about the ulcers. These ulcers may be quite extensive—even three square centimetres (an inch or more)—in area.

This ulcerative stage is that in which the affection is usually encountered. Whether the affection will recover spontaneously is questionable. Perhaps it might in healthy children who are only slightly attacked. Parrot, however, treats all his cases from the beginning. When the treatment acts successfully, the discharge and tumefaction

soon diminish, the borders of the lesions sink, and by the end of twenty-four hours the lesions are level with the skin; they grow smaller and smaller, and finally disappear without leaving any mark or cicatrix.

When the case is improperly treated, or when left without treatment, the ulcerative process goes on, and gangrene may result.

Gangrene is not, properly speaking, a complication of aphthous vulvitis, but is rather one of the forms of this disease which may show itself under circumstances as yet imperfectly. When gangrene is about to supervene, the ulcers are seen to become covered with grayish-brown or blackish patches; the adjacent parts become livid, swollen and indurated, and painful. When sphacelus does occur, it proceeds with great rapidity, preceded by the redness and tumefaction of the parts about to be attacked. In some cases it seems as if nothing could arrest the disorganizing invasion of the disease. Parrot has seen not only the vulva and labia destroyed, but, in part, the perineum, anus, rectum, and the skin about the thighs in the neighborhood, and the coccyx. All the mortified parts are black as if stained with ink, and give out a fetid odor. When the patients survive, the eschars, which are always moist, are detached in large pieces, leaving such considerable lacunæ of tissue that it seems scarcely possible they can be filled up. However, the reparative action is often as active as the destructive action which had preceded it, and the loss may be entirely made up.

Constitutional disturbance does not generally show itself except in the gangrenous variety, and this latter, though usually consecutive to aphthous ulceration, sometimes occurs independently of it.

The ordinary variety of aphthous vulvitis follows a different course according to the seat of the lesions. Those about the anus are apt to be the slowest in healing, and no case should be considered cured until the folds of the anus up into the rectum are carefully examined. It is a curious fact that the inguinal and other neighboring glands are not enlarged.

The etiology of aphthous vulvitis is one of the most interesting points in the study of this disease. As to age, thirty-three out of fifty-six patients were between two and four years old. As to sex, Parrot remarks that he has met with one case of balano-posthitis in a little boy. Measles occurred in thirty-nine cases, showing a very strong causative connection between this fever and the aphthous ulceration. It would be going too far, however, to consider this relationship as constant. Prof. Parrot found the aphthous inflammation in no fewer than sixteen cases where there was no pyrexia. Whooping-cough, varicella, erysipelas, pneumonia, and diphtheria have each been noted in connection with the affection under consideration, but it is questionable how far they may have any specific causative influence.

The treatment of aphthous vulvitis is a matter of much moment. At first Parrot used to employ the usual remedies in vogue, — topical emollients, cataplasms, tonic, detersive, and absorbent powders, as charcoal and quinine, aromatic wine, chlorate of potassium,—all without avail. At present he is much more successful, thanks to a single topical application,—iodoform. As soon as the affection has developed, a fine layer of iodoform powder is applied to the affected parts on a bit of cotton, and the opposing sides are kept apart by means of patent lint. This application is renewed every twenty-four hours until a cure is attained, which is not very long. The anus does not yield so easily to treatment as the vulva, but it does heal after some weeks, and these masses of sphacelus formerly observed are no longer seen.

THE CHARACTERISTICS OF CICATRICES. —Prof. Parrot (*Le Progrès Médical*, June 11, 1881), in a lecture on the traces of hereditary syphilis in infants, describes the various scars left by eruptions of different kinds, as follows.

The cicatrices of variola are scattered over the general surface, but occur chiefly upon the face. This topography, as well as their irregularity, distinguishes them from the scars of syphilis. The cicatrices of varicella, when present, are chiefly found upon the face; they are small, and do not show a pigmentary zone at any time. Impetigo affects chiefly the scalp, and after cure leaves little or no mark. The same may be said of pemphigus, scabies, and ecthyma. Syphilitic gummata are usually situated upon the limbs; they result in large, deep ulcers followed by irregular cicatrices often adherent to the adjacent parts. The scars of burns are easily distinguished; they are large, of irregular

contour, pearly-bluish in color, often covered with ridges, and without any specific location. They are often seen side by side with syphilitic cicatrices, but there is no difficulty in distinguishing them. The scars left by croton oil are punctate, more uniform than those of syphilis, and are usually found grouped on the abdomen or some particular part of the thorax.

The scars of syphilis as found in children are circular in outline, with a regular contour, though this may not be very sharply defined. Depending upon the time they have lasted and other circumstances which usually escape us, they are slightly raised above the general surface of the skin, or more frequently are depressed, perhaps to the depth of half a millimetre. Their surface is often smooth; at other times it is a little irregular, with small depressions. No ridges or bridles are ever seen. The color of the lesions is a matter of great interest; it varies with their age. Usually it is at first uniform and of a violaceous tint, but soon it changes to three distinct shades,—in the centre a whitish disk which grows whiter every day, then a violaceous zone, and at the extreme periphery a second band of brownish red, less sharply defined than the preceding. Little by little the red or violaceous coloration observed at first is effaced, while the white becomes more distinct and the brown areola darker. The latter is much more marked in brunettes. In blondes it is sometimes almost invisible. It persists a long time, but disappears finally, and cannot usually be detected after the sixth year. The cicatrices also gradually disappear, and after adolescence can often only be discovered by the aid of a lens.

A Contribution to the Histology of Keloid.—Schwimmer (*Cbl. f. Chir.*, 1881, p. 339; from *Vierteljahrschr. f. Derm. u. Syph.*) saw, in one case of a woman 35 years of age, one hundred and five spontaneous keloid tumors, varying in size from bean- to thumb-size, and mostly seated upon the right breast and right side of the back. The tumors were firm, slightly movable, mostly covered with normal skin; here and there one was shiny red and showed numerous small vessels. Some were roundish; others showed processes running into the neighboring skin. The affection had developed slowly during six years, without giving rise to subjective symptoms. No cause for the appearance of the tumors could be ascertained. On extirpation of a tumor, another one formed in its place.

A second case occurred in a healthy girl of 17. The appearances were the same as above, the seat of the tumors being in the right half of the thorax. Some tumors had coalesced and looked like manifold-lobed bladders. On the trunk scar-like white patches were found strewn. The largest tumor having been extirpated and its seat cauterized, a healthy scar was still existent five months later, around the borders of which, however, could be seen a slight, suspicious elevation.

Microscopic examination showed atrophy of the epidermis, the formation of peculiar vesicles and nuclei, disappearance of the papillæ, atrophy of the hair-follicles and sebaceous glands. The tumors were found to begin directly under the epidermis, and to consist of thick and thin fibres running parallel to the surface. The tissue was richer in cells than fibrous tissue, and showed numerous endothelial cells from obliterated vessels. Vessels were rarely present. The sclerotic connective-tissue bundles appeared to start from them and run crosswise through the tumor.

The appearances thus presented are different from those noted by Langhans and Kaposi, from the fact that atrophy of the epidermis was present and that the tumor was not sharply defined from the normal tissues in which it lay. It was not, however, a cicatricial keloid, since the tumors arose spontaneously and the arrangement of the fibres was different.

Tincture of Winter-Green as an Antiseptic.—Dr. Gosselin (*Arch. Gén. de Méd.*; from *Bull. Gén. de Thérap.*, 1881, vol. i. p. 335) uses two solutions,—No. 1 containing 5 grammes of oil of gaultheria; No. 2 containing 2.5 grammes of the oil to 100 grammes of alcohol and 50 grammes of water. These solutions are antiseptic and have been used with success in dressing wounds.

A New Febrifuge.—M. de Vry (*Revue de Thérapeutique*, 1881, p. 286) describes a new febrifuge,—borate of quinoidine. Among other advantages, the new remedy is said to cost only one-tenth as much as sulphate of quinia. It is somewhat less active, however, than the latter well-known medicine, doses of double the weight being required to produce the same effect.

PHILADELPHIA
MEDICAL TIMES.

PHILADELPHIA, SEPTEMBER 10, 1881.

CORRESPONDENCE.

LONDON LETTER.

THE great International Medical Congress has come and gone, and a monster gathering it has been,—one that will be memorable for long,—representatives of medicine from far and wide. France sent Charcot, Bouchut, Léon Labbé, Guéneau de Mussy, and others; Germany, Virchow, Langenbach, Liebreich, Volkmann, Busch, and a host more of well-known names; Braun, Kaposi, and a few more came to represent Austro-Hungary; Italy sent Bacelli, Tommasi, Casselli, and other illustrious representatives of medicine; Donders and Stokvis head the list of those who came from Holland; Reverdin brought some colleagues from Switzerland; Russia sent a contingent with the most wonderful names; while other countries, even to the Argentine Republic, were represented. The United States of America were well represented by Fordyce Barker, Austin Flint, Marion Sims, Lewis Sayre, G. M. Lefferts, Paul Mundé; by Bigelow, Otis, H. C. Wood, Minis Hays, Billings, D. W. Yandall, R. Battey, Davis, of Chicago, and a legion of others whose names are too numerous for mention. The venerable and sombre College of Physicians looked quite gay with the awning on each side of the entrance,—like an old dame in a clean apron. The informal reception was held on Tuesday afternoon, when the College was crowded by faces and figures unwonted and unfamiliar to it. Some new pictures were mustered to smarten up the old walls. On Wednesday morning the first meeting was held in St. James's Hall, which was completely filled. Royalty was present in the form of the Prince of Wales and his brother-in-law the Crown Prince of Germany. Sir William Jenner opened the proceedings, speaking somewhat nervously, interrupted by repeated bursts of applause. William MacCormac, the Honorary Secretary-General, then read a lengthy report, which was listened to somewhat impatiently. He told of the labors of the officials, the generosity of certain bodies allowing their halls to be utilized for sections, the myriads of circulars issued,—indeed, the Atlas-like performance which had been achieved. Letters in their native languages had been addressed to such foreign potentates as the Emperors of Russia and Japan and others, who had graciously acknowledged their receipt. The names of the commissioners from the various foreign countries were then formally read. He concluded by announcing that a commemorative medal had been struck, in the preparation of which some of our first artists had been engaged, so that "no effort had been spared to render the meeting a success." This tedious matter being completed, Sir James Risdon Bennett, as Chairman of the Executive Committee, then spoke, bursting into French, to the surprise of many, giving all a hearty welcome. The Prince of Wales, who is a very happy speaker, then spoke a few sentences which called forth repeated applause, and declared the Congress open. After this, Sir James Paget delivered an address in his wonted mellifluous language, in which he alluded to the advantages which accrued to all from such gatherings, with their interchange of thought; pointed out how an intellectual advance in one direction was usually accompanied by almost synchronous progress in others, instancing how the researches into minute organisms apparently destitute of any practical value had led to some most important doctrines in organic chemistry,—had brought about a most beneficial change in practical surgery, and promised to do as much for medicine; they concerned the highest interests of agriculture, while their influence probably did not rest here, but had promise in the future. It was all spoken in the most natural manner, yet it is asserted that it was a great mnemonic feat, as it was all already in print and was committed to memory word for word. If this is so, it only makes it all the more remarkable as a performance of no ordinary character.

The first meeting was a complete success. At 2 P.M. the Sections commenced work in earnest. The Anatomy Section was presided over by Prof. Flower, F.R.S., supported by Macalister, of Dublin, and Turner, of Edinburgh. Physiology was presided over by Michael Foster, F.R.S., the illustrious Cambridge professor and well-known author of the Hand-Book, with Pavy, F.R.S., Rutherford, F.R.S., of Edinburgh, and Purser, of Dublin, to assist him. Pathology found S. Wilks, F.R.S., worthily filling the chair, with Sayer Bristowe, F.R.S., Jonathan Hutchinson, and Burdon Sanderson, F.R.S., as Vice-Presidents. In Medicine, Sir William Gull, F.R.S., presided, supported by Prof. Gairdner, George Johnson, F.R.S., R. Quain, F.R.S., and William Roberts, F.R.S. Surgery found Erichsen in the chair, with E. H. Bennett, of Dublin, Humphrey, F.R.S., of Cambridge, and Savory, F.R.S., supporting him. In Obstetric Medicine, McClintock, of Dublin, was in the chair, with Barnes, Braxton Hicks, F.R.S., Matthews Duncan, and Priestley as Vice-Presidents. Diseases of Children was presided over by West, aided by Dr. Gee and Timothy Holmes. In the Section devoted to Mental Diseases, Lockhart Robertson was in the chair, supported by Crichton Browne and Maudsley. The ninth Section embraced Ophthalmology,

with Bowman in the chair, and Critchett, Henry Power, Argyl Robertson, and Swanzy as Vice-Presidents. Diseases of the Ear found Dalby presiding, with Cassells, of Glasgow, and Fitzgerald, of Dublin, to support him. The eleventh was devoted to Diseases of the Skin, where Erasmus Wilson presided, with Cheadle, of St. Mary's Hospital, and Liveing to assist. Diseases of the Teeth had Edwin Saunders in the chair, with Tomes, F.R.S., and Spence Bate, F.R.S., as Vice-Presidents. The thirteenth was State Medicine, presided over by John Simon, having for Vice-Presidents George Buchanan, De Chaumont, Norman Chevers, Douglas Maclagan, and Netten Radcliffe. Military Surgery and Medicine had as President Prof. Longmore, with Sir William Muir, Dr. J. W. Reid, and Sir Joseph Fayrer, K.C.S.I. and F.R.S., as Vice-Presidents. Last, but not least, Materia Medica and Pharmacology brought up the rear, with Prof. Fraser, of Edinburgh, in the chair, with Lauder Brunton, F.R.S., Rawdon Macnamara, and Sidney Ringer, as Vice-Presidents.

It would be invidious to attempt to contrast one Section with another: there was plenty of work for all. Representative men were found in all Sections. I have the honor to conclude the big volume of over seven hundred pages, containing abstracts of the papers to be read in the different Sections; and when my paper was read, Lauder Brunton, H. C. Wood, and Sidney Ringer were there, the two first taking part in the discussion on "Strychnia as an Expectorant;" so that personally I can have no grounds for grumbling: and I believe others regarded themselves as equally fortunate. In each Section the President gave an introductory address, and Prof. Fraser told how the recent Anti-Vivisection Act was carried out practically. He had been refused a license to test the properties of a poison used by the natives of Borneo on their arrows, by the subcutaneous injection of the poison to rabbits. Scientific research in England is evidently arrested for a time when even this may not be done by the successor of Sir Robert Christison in the chair of Materia Medica in the University of Edinburgh. The work accomplished everywhere told of zeal and enthusiasm, of an honest appreciation of the work of all, the speaker and the listener alike and in turn, each as ready to act as to learn, to listen as well as to be listened to. All, however, "knocked off," in workman's phraseology, early, to listen to Rudolph Virchow give an address on "The Value of Pathological Experiments." It appears that a new society for the protection of animals has been established in Leipsic, which is agitating for a law to punish vivisection by imprisonment and deprivation of civil rights. He held that if the advocates of vivisection cannot make good their claim before the world the cause must be looked on as a lost one. He pointed out how dissection of the human body fought its way against tremendous opposition. The discovery of "cells" was then given as an illustration of the aid science can give to medicine. He spoke warmly on behalf of the study of symptoms, now so much neglected. "Have symptoms no more any importance for the physician? Can a diagnosis be made without a knowledge of symptoms?" he asks, with a ring of audible scorn. It is the "why" of symptoms which gives them their value to the scientific physician. The progress of ophthalmology was used as an illustration. "The principle of modern medicine," he said, "is localization." Much more followed, wise, thoughtful, right-minded, and full of interest, well worth reading and study by all, but which cannot be reproduced here: the address can only be recommended. It concluded with an eloquent defence of vivisection and vivisectors, their motives and their practices, against the calumnies uttered by their opponents.

After this address there followed a swift and complete dispersion of the individual units to their different festive entertainments, where hospitality profuse and unstinted was shown on all sides. Perhaps there may have been individual exceptions, but the general testimony was satisfaction to repletion; and with the genial enthusiasm and *bonhomie* consequent upon a good meal, all met again at 9.30 in the South Kensington Museum to a conversazione, at which the Prince of Wales and the Crown Prince were present. This ended the first day.

On Thursday morning, work commenced by an exhibition of some rare cases of living specimens in the Museum. A large number of the foreign visitors spent their morning in going over the leading hospitals, as Guy's, the London, St. Thomas's. It indicates the managing powers of the Congress that none of the many excellent special hospitals which exist in London, and which are quite taking the lead of the general hospitals in their special departments, were noticed at all in the proceedings. In the Section on Diseases of Children, Lewis Sayre's treatment of spinal curvature was resumed in discussion. All thinking and reflecting surgeons see the soundness of the plan and the utility of his jacket in bending and yielding spines, as a preventive, as well as in the rectifying of distorted spines.

The subject of localization of function in the brain received a considerable amount of attention. First, Brown-Séquard had his say against it; then Prof. Goltz blew his trumpet on the same side, and exhibited a dog in which he had successfully (?) destroyed all the so-called cerebral centres except the anterior-frontal convolutions; yet the animal, eight months after this mutilation, performed all its movements in a normal manner. Thus challenged, Prof. Ferrier trumped Goltz's card

with a monkey in which the centre for movement by flexing the fore-legs was destroyed, the animal manifesting undoubted and indisputable evidence of a corresponding loss of power. In this case the mutilating operation had also been performed a number of months previously.

The subject of antiseptic surgery was thrashed out in the Military Surgery and Medicine Section. Some microscopical demonstrations of double and treble staining of tissues were given. The address on "Le Scepticisme en Médecine, au Temps passé et au Temps présent," to have been delivered by the late Prof. Maurice Raynaud, of Paris, was read by his friend Dr. Féréol. A banquet was given in the evening by the Lord Mayor to two hundred and sixty of the members of the Congress. Here was again much private entertainment also.

On Friday all was in full swing at the sectional meetings. The subject of oöphorectomy was started by its originator, Battey, who pleased those whom he did not convince as to the possibility of diagnosing a misplaced ovary by external manipulation. At the conclusion of the morning sitting in the Obstetric Section was held a meeting of American delegates to constitute a committee to thank the Britisher for his hospitality. Pallen was asked to take the chair, and he presided admirably. The stalwart figure of D. Yandell was seen to erect itself, and shortly the deep notes of his sonorous voice were heard in all their impressive slowness. The scene was an interesting one for a person who is not personally acquainted with Americans. The sonorous "ay," "ay," heard from all parts of the room when a motion was put, reminded one of the old Puritan ways, and contrasted with the noiseless lifting of the hand which is the practice with us. A handsome, tall, well-built crowd they were, very English-looking, —not one corresponding to the American type of the caricaturist. Their expressions of satisfaction with their treatment were very gratifying to the ear of one of their hosts. The visits to the hospitals were resumed. The eloquent address of Dr. Billings on "Our Medical Literature" was listened to attentively by an admiring audience. Among other matters, he contrasted the profusion, the luxuriance of growth, of medical journals in his own country, with the paucity of like journals in England,—her old journals, however, being planted in very secure foundations, while very few new ones were started.

The medical ladies were indignant at being excluded from the Congress, and, smarting under the indignity, held a garden-party at their School of Medicine in the afternoon, at which a number of sympathizers were present. (The daily press gave more prominence to those present at this gathering than at any other in the Congress. *Absit omen!*)

In the evening one of the most striking of all the receptions was held, viz., a conversazione in the Guild-Hall, given by the Lord Mayor and Corporation of the City of London to a certain number of the members of Congress and their ladies. The hospitality was at once generous and genial. A selected number of guests were invited; but the Londoner repeated what he practised when the British Medical Association was here in London,—viz., pushed in himself and almost overlooked his guests. Many who might very fairly have expected to be invited among these guests were overlooked, while very ordinary Londoners moved heaven and earth, or their local city equivalent, to procure tickets for themselves. Fortunately, all the rooms were thrown open, so that there was space for all the multitude who thronged there, to see a sight probably few will see again. But of this I speak only from hearsay.

On Saturday morning the Sections went to work with a will, as there was much to be done in the way of excursions. In the Materia Medica Section, H. C. Wood opened a discussion on a most interesting subject,—"The Nature and Limits of Physiological Antagonism." The subject of nephrectomy received further attention.

But Saturday is the day of excursions *par excellence*. At noon a large party went to visit the Sewage Farm of Croyden, to inspect the works, the farm, and the river Wandle, into which the outflow of the sewage farm falls, bright and transparent and containing shoals of fish. Others went to Folkestone to do honor to the memory of Harvey, the discoverer of the circulation of the blood, who was born there in 1578. On the tercentenary of his birth a memorial window was placed in the parish church. A movement was set on foot by Dr. G. Eastes, a member of the Harveian Society, to erect a statue to his memory at the same time, which has been successful. A handsome statue of Harvey was unveiled by Prof. Owen, C.B., who delivered an address in which he eloquently defended the practice of vivisection from the aspersions and calumnies of its wrong-headed opponents. The Southeastern Railway granted free passes, and the Mayor and Corporation entertained the visitors afterwards in the Town Hall with a handsome collation. Others wended their way to Hampstead as the guests of Mr. Spencer Wells, and enjoyed the garden-party much. In the evening a dinner was given to a party of the members at the "Star and Garter," Richmond Hill, by the United Hospitals Club. All were ready for a quiet Sunday, regretting that Dean Stanley could not deliver the sermon which he had promised and to which all had looked forward with so much anticipation. The genial catholic-minded dean was lying beside his wife in Westminster Abbey, having died of erysipelas just before the meeting of the Congress. Stanley, Rolleston, Raynaud, and many more who were

to have taken part in the Congress have been removed by death since the first arrangements were made. Mr. Erasmus Wilson had a party of fifty down by a special train to visit him for the day at Margate. For the bulk who remained at home the Botanic Gardens and the Zoological Society's Garden were thrown open. One of the curious accidents of imperfect arrangement was that on visiting the Zoo and presenting their card of membership the porters refused to admit any lady. "The card admits the member only," was the steady answer. To whose fault of omission or whose "pure cussedness" this ungallant conduct is due is unknown; but the step gave universal offence. It was at once uncalled for and discreditable; for the Zoo was just the place of all places to which to take a lady. Nor was the company gathered there very select. Most of the subscribers to the Zoo had left town and given the tickets remaining unused to their domestics, who naturally wished to see the doctors. Consequently, the members of the International Medical Congress had ample opportunity for observing on a large scale the domestics of our "good families" and their friends,—a well-behaved but not very distinguished section of the body social. This, together with the refusal to admit "ladies" with the members, excited a good deal of sharp criticism.

On Monday, the Sections went to work with a "slaughter of the innocents" in the way of getting through the papers remaining unread. The great event of Monday was the garden-party given by the Baroness Burdett-Coutts in the afternoon. The weather, which had hitherto been all that could be wished, became contrary, probably surprised at its own good conduct, and a steady rain spoiled the programme, though some thousand and odd were entertained in-doors. In the evening a dinner was given to the foreign members by the Society of Apothecaries, and later on there was a conversazione at the Royal College of Surgeons, which was well attended.

Tuesday was the last day. The Sections worked off their list as best they could. At 2 P.M. there was a general mutual-laudation meeting, as is the usual finish to such gatherings. Those concerned patted each other on the back, complimented each other, and were certain all had been managed to the best of human ability. And, on the whole, the thing was fairly managed. Of course there were "hitches," and some visitors overlooked who ought to have been honored; but, after all, the thing was creditable to man in his unglorified state. The seventh meeting of the International Medical Congress was declared a complete success,—"the largest gathering of medical men ever known." The weather had repented itself of its outbreak of temper, and it was once more sunny and breezy when the remains of the Congress betook themselves to the Crystal Palace for a spell of relaxation. A few wended their way to the Isle of Wight to take their part in the annual meeting of the British Medical Association, which commenced at Ryde on Tuesday, the 9th, under the presidency of Mr. Benjamin Barrow. Certainly some fresh air and a taste of the "briny" would be very acceptable after the sojourn in London. And so ended the "monster Congress," and—well, we are glad it is successfully over.

The meeting of the British Medical Association was a small one indeed,—but the semblance of a meeting; nor was there anything of interest brought forward in the Sections. Any man who had anything to say delivered himself thereof at the Congress. The British Medical Association meeting was but the "after-pains" of the act of parturition.

J. MILNER FOTHERGILL.

PROCEEDINGS OF SOCIETIES.

AMERICAN DERMATOLOGICAL ASSOCIATION.

FIFTH ANNUAL MEETING.

Held at NEWPORT, Rhode Island, August 30 and 31 and September 1.

THE first day's proceedings were opened by an address from the President, Dr. James Nevins Hyde, of Chicago, entitled

THE RELATIONS OF DERMATOLOGY TO PERIODICAL MEDICAL LITERATURE.

After alluding to the addresses of his predecessors, which contained an account of the rise and progress of American dermatology, the speaker said it was his purpose to inquire briefly what may be rightly expected of periodical dermatological literature in its attempts to supply the needs of the profession at large, respecting chiefly the diagnosis and treatment of skin diseases. Such literature exists in the form of special journals on one hand and current general medical issues on the other. The list of the former is limited, their subscribers also are limited, and the number of general practitioners who consult them is smaller still. Most medical men derive their knowledge of dermatological subjects, limited or the reverse, from the vast number of general medical journals published here or abroad.

Contributions on dermatology to general medical journals, which, from their wider circulation, secure a more extensive reading, may be assigned to four categories:

1. Solid and praiseworthy observations of fact, or deductions of a trustworthy character from the observations of others.

2. Reports of imperfectly-observed facts, and crude opinions derived from these imperfect observations.

3. The worthless papers of men totally ig-

norant of the meaning of the terms they have attempted to employ and of the significance of the relation of the facts observed to each other or to other facts beyond the scope of their recognition.

4. A class of papers which are negatively a source of mischief, worked chiefly, however, to the authors themselves. These are written by men who should know well the subjects which they attempt to discuss, if we judge them from the stand-point of position and experience. But, either from an undue haste originating in the pressure of many duties, or from a foolish desire to identify themselves speedily with the subject upon which they write, or even from other motives not of the highest character, they deluge the medical press with voluminous papers filled with verbose iterations of ideas made public before their day, often by others in much better form, which serve to encumber the world with a little more of the rubbish swept annually by a pitiless indifference into the limbo of the forgotten.

A comparison of the papers published in the last few years with those of an earlier date shows a very marked improvement and promises well for the future. On some topics, however, there is room for more extended knowledge among the mass of the profession; and these are just the ones where the possession or absence of information will make the difference between brilliant success and dismal failure.

The speaker then went on to allude to the various affections of the skin in which mistaken diagnoses are frequently made, and touched upon the popular errors in etiology prevalent. Some of the popular errors which require refutation or correction are the following:

1. That because a disease exists and is visible on the surface of the body it for that reason alone requires active internal or external treatment. Some diseases of the skin need no treatment. These cases occur to all of us in our daily experience. The speaker had recently observed forty cases of rötheln, in not one of which was any drug administered, and in none did any accident occur worthy of mention beyond the usual features of the disease.

2. That because a disorder of the skin exists it can always be readily relieved by an expert. There are cutaneous maladies which prove inevitably fatal. There are others of such an inveterate character that the skill of the most practised is unable to give relief.

3. That, after relief is secured by treatment, many diseases of the skin may be so managed that they will not recur. This implied demand seems to be made upon the dermatologist alone. The patient with a fractured leg does not ask of his surgeon a guarantee that he will not suffer a similar accident if he again falls beneath the wheels of a rolling car. The convalescent from a follicular enteritis does not demand a future immunity from errors of diet in an unfavorable season or an unpropitious climate; and so the patient with a disease of the skin should not expect to be protected against the results of neglect or imprudence. Some diseases of the skin recur continually and will do this for a lifetime. It is true that these recurrences usually result from adverse extrinsic influences; but it is often not in the power of the physician to set these aside. In such cases he discharges his full duty when he forecasts the future and describes the results of the best treatment under forbidding circumstances.

4. That the expert, upon examination of but a portion of the affected integument, is competent to pronounce at once upon the character of a disease. No opinion is worth the time of the patient or consultant which is not based upon a most careful, exhaustive, and patient investigation, not only of the visible symptoms present to the eye upon the surface, but also of the history of the case and all other pathological facts obtainable. Strange that the dermatologist alone should be supposed absolved from the necessity of a careful study of his cases. It is a common experience to be shown a patch of diseased skin or a few distorted hairs, upon which follows the inevitable question, "What do you call this?" The speaker had recently been stopped on the street by a physician of large practice and wide reputation,—doubtless on his way to the bedside of his patient,—who hurriedly demanded, "Please tell me how to treat eczema?"

5. That a practising physician need not always make an accurate diagnosis, and that a failure on his part to do this need not be considered as perilous to himself. The time has passed when intelligent patients can be put off with a long-sounding name and a prescription written in a dead language. For many of them it will no longer suffice to be informed that they are affected with a "disease of the skin." They demand what the affection may be, and sooner or later patients of this class lose confidence in the physician who attempts to treat without knowing the name or nature of the affection with which he has to deal, and find out for themselves the person who is competent to describe their condition and to advise them judiciously with regard to its management. We, who often are consulted at this juncture, are sometimes compelled to listen, with a feeling of shame for our profession, to indignant reproaches on the lips of those who but a brief time before trusted to the honor and relied on the skill of our brothers in medicine.

Let no man regard these statements in the light of a plea for a wider range of possibilities for the consultant. The educated gentlemen who have made themselves masters of any special department of science, in this

country, certainly have found no lack of appreciation and that reward for skilled labor which all honest work inevitably yields. They surely need have no plea entered for them. This Association has steadily set its face in the direction of the needs of the physician in general practice with respect to a knowledge of cutaneous diseases, and has made a most important and valuable advance in the diffusion of such knowledge in America. If the words of the speaker could be interpreted as a plea, they should be held as pleading for higher attainments on the part of the general practitioner.

6. That such remedies as mercury, arsenic, and the iodide of potassium may be administered in any case where an accurate diagnosis has not been established, and in such cases may be used unadvisedly. Said the physicians of a past generation, "When you do not know what else to do, treat for syphilis." It is difficult to touch upon this point without seeming to exaggerate. It is not too much to say that for one patient who is benefited by the administration of these remedies in the hands of incompetent men, there are ten who are made worse. The vulgar idea that all disorders of the integument are in some obscure way to be connected with a syphilitic taint in one generation or another, the erroneous opinion that syphilis descends through many generations and lurks obscurely in the eczema of the infant, the psoriasis of the adult, the sycosis of the young man, or the acne of the young woman,—these are the spectres that scare the foolish, whether they call themselves doctors or laymen. It should be considered a crime to subject a man or a woman to a systematic mercurial course for the relief of an affection supposed to be syphilitic, but in reality not such.

7. Lastly, that the study of diseases of the skin is the pursuit of a narrow specialty, leading to a knowledge of superficial eruptions upon the surface of the body, and to an ignorance of the functions and maladies of important internal organs. Yet he who would specially devote himself to the investigation of the disorders of the skin requires fully as much as his fellows the amplest preparation in a finished medical education and experience, and when at last ready for his work he will discover, if he has not done so before, that he needs to be a physician in the highest sense of the term. There is no organ of the body, in health or in disease, which it may not become his duty to explore and investigate.

In conclusion, the speaker said that he had appended to his address a general alphabetical index, by authors and subjects, of all original communications which have appeared in the pages of our special dermatological journals, including also the papers written by members of the Association and published elsewhere.

Dr. Charles Heitzmann, of New York, read a paper entitled

A CONTRIBUTION TO THE MINUTE ANATOMY OF THE SKIN.

The writer described investigations made by himself in normal skin, chiefly as to the structure of the hair, going to show that the prevalent views as expressed in text-books and shown in pictures of the microscopic appearance of normal hair are erroneous and require revision. They are chiefly based on the researches of Biesiadecki, Kölliker, and himself, made many years ago, each subsequent writer having copied his predecessor or having at most blindly followed these investigators. The structures of the hair were simpler than described. The paper was accompanied by a number of drawings, and, in addition, by a complete and perfect section perpendicularly through the centre of the hair, perhaps the finest which has ever been made, and which showed each structure as in a schematic drawing.

Dr. James C. White, of Boston, read a paper entitled

THE LIMITATIONS OF INTERNAL THERAPY IN SKIN DISEASES.

The writer said he would like to approach the consideration of the subject from a purely empirical stand-point, uninfluenced by theories and traditions, and supported only by the results of observations made and recorded in ways recognized as strictly scientific. Cutaneous pathology offers an exceptional field for the study of drugs introduced through the stomach; for, in addition to the ordinary means of judging their effect, the phenomena of tissue-change or modification of function occur directly under the eye. Yet cutaneous internal therapeutics is no more fixed or satisfactory in its results than the therapeutics of general medicine. In spite of great activity and the fact that novelties even called specifics in skin diseases are scattered all along the history of medicine, only a few agents have attained and preserve a well-established reputation as serviceable in limited fields of usefulness. Dermatologists of repute in different countries still adhere to certain remedies from motives of conservatism or patriotism, while those of other countries cling to their pet drugs and regard foreign treatment as obsolete and erroneous. This unsatisfactory and contradictory condition of affairs must continue until better methods of study are adopted and the faults of individualism eradicated.

It would not be boastful to say that nowhere does there exist a body of dermatologists so broadly cosmopolitan in spirit and training, and representing such varied opportunities of research as are afforded by wide differences in climate and race, or one more

competent for such work, than the gentlemen who compose the American Dermatological Association.

The writer went on to sketch an imaginary committee who should conduct a systematic investigation of new drugs. When a member of the Association should present a paper on the specific effect of some drug in this or that affection, this would be submitted to the committee, who should follow some well-established procedure in testing its merits. In this way the Association would do much to discourage the loose writing and the claims based on insufficient observation which generally herald the introduction of each new remedy. To such a committee might be referred not only all appropriate communications presented to the Association, but all doubtful questions of importance in therapeutics, which now vex us so frequently, of old or new origin.

The following subjects of investigation might be cited by way of illustration:

1. The action, beneficial or injurious, of our most celebrated springs in affections of the skin. A report on this subject would do much to clear away the atmosphere of charlatanism which has hitherto obscured it, and develop some knowledge of certain characters regarding it, which the profession of this country has so long needed.

2. The power of electricity over the so-called neuroses of the skin (including zoster).

3. To what extent may certain substances in common use be applied to the skin without danger, viz., compounds of zinc, lead, mercury, carbolic acid, etc.?.

It is unfortunate that so few beds in hospitals are under our control, and that we must rely upon the voluntary visits of out-patients. But, even with such opportunities only at our command, much may be done.

The speaker then went on to speak of the vague and meagre knowledge possessed on the action of drugs on diseases of the skin, as illustrated in systematic treatises, going over each class of diseases *seriatim*, and stating the amount of exact knowledge possessed as to the influence of drugs internally administered on each. The number of individual affections of the skin recognized by us approaches closely one hundred. How many of these are under the direct control of internal medication in any uniform or marked degree? The speaker wished he might claim such power over ten of them,—such power as arsenic may exhibit in psoriasis, as mercury almost always does in syphilis, and which makes external treatment unnecessary.

The writer did not mean to deny that much may often be done to hasten their good work by the simultaneous use of remedies which elevate the general tone of the patient's functions and tissues, when needed, together with local treatment. The whole patient must always be considered. Moreover, the writer did not believe that the narrow limit of our exact knowledge on this subject could not be enlarged. He would encourage any experimental studies, empirical or philosophical, in this direction. It is the manner in which this important subject has been hitherto so generally treated, so detrimental to scientific progress, which he deprecated. But a frank confession of our present inabilities is an essential step in any real advance.

Dr. Heitzmann expressed his pleasure at hearing such sceptical views expressed. Men like Erasmus Wilson had done serious injury to dermatology by hastily asserting the influence of internal medication in diseases of a purely local character and indiscriminately.

(To be continued.)

REVIEWS AND BOOK NOTICES.

THE MOTHER'S GUIDE IN THE MANAGEMENT AND FEEDING OF INFANTS. By JOHN M. KEATING, M.D., Lecturer on Diseases of Children at the University of Pennsylvania, etc. Philadelphia, Henry C. Lea's Son & Co., 1881. 12mo, pp. 118.

This is one of the best books of the kind we have ever seen. Though popular in the sense of being intended as a hand-book for young mothers of the more intelligent classes, it is strictly scientific. Dr. Keating possesses the fortunate faculty of being clear and concise while writing in a charming style, which makes his little book entertaining reading. He considers his subject under three heads,—the general management of the infant from birth to dentition, general management during dentition, and management after early dentition. Most of his counsels are of a hygienic character; but he also gives some directions for the guidance of mothers whose children may be attacked by sudden illness when far from the aid of a physician. We can cordially recommend this mother's guide to the notice of physicians desiring to place a work of the kind in the hands of their patients.

GLEANINGS FROM EXCHANGES.

REMARKABLE CASE OF SYPHILITIC ENDARTERITIS OF THE CEREBRAL ARTERIES IN A CHILD AGED FIFTEEN MONTHS.—Dr. H. Chiari, of Vienna, gives the following case. A female child, apparently healthy, was born at full term, of a mother aged twenty-one years, who had been married about four years to a man suffering from syphilis. She had previously been delivered of a dead infant, ten months after her marriage, and nearly two years after was treated by Prof. Zeissl for

roseola and ulceration of the pharynx and tonsils.

The first six weeks of the child's life were free from disease; then moist papules appeared about the anus and poisonous patches on the feet and hands; later, other pronounced syphilitic lesions occurred. After those first described had yielded to treatment, these (faucial ulcers, nasal catarrh, epidermic lesions) also yielded to treatment. At the age of eleven months, symptoms of central nervous affection were observed,—viz., ptosis of the right eye, dilatation of left pupil, paralysis of the right facialis; also apparently a gummy tumor on the right half of the tongue. Despite treatment, the child continued to emaciate, the symptoms persisted, and four months later the right side of the body was completely paralyzed. Epileptic attacks closed the sufferings.

Post-mortem examination.— Large fontanelle still open; inner meninges, in general, markedly œdematous and somewhat thickened; many small, flat, whitish patches on the arachnoid and pia, both over the convexity and the base of the brain. There were counted at least twenty such patches of large dimensions over the left cerebral hemisphere, besides many smaller ones, and perhaps as many over the right; about the large basal arteries of the brain there was moderate thickening; the most of these, and especially the vertebrals and basilar, exhibited great alterations; their walls were thickened and hard to the touch. Upon making sections into the vessels the following was noted. The basilar artery in its posterior two-thirds and the vertebrals in their upper parts were completely obliterated by a softish tissue. In both vertebrals, just below their obliteration, were old blood-clots, making complete thrombosis. Both internal carotids and the sylvian arteries, especially the left, had irregularly thickened walls; the other arteries of the brain appeared of delicate structure. The brain itself contained a moderate amount of blood, and was very soft. The cerebrum exhibited here and there, both in the medullary portion and in the large ganglia, whitish-yellow masses of distinct contour and varying in size up to a pin's head. The ventricles were of the usual dimensions. The right facial nerve was somewhat thicker than the left. There were characteristic ulcers of the larynx, soft palate, and tonsils. The liver was rather firm.

Microscopic examination.—The inner meninges everywhere exhibited an infiltration of small cells; the flat, whitish patches proved to be products of inflammation, as they consisted of granulation tissue and dilated vessels. The arteries at the base of the brain illustrated perfectly the so-called syphilitic endarteritis. Cross-sections in the posterior two-thirds of the basilar artery showed this vessel to be filled with gummy connective tissue, with numerous round cells, spindle cells, and cells with several processes. There were brown pigment-granules in the connective tissue, and perfect blood-vessels, capillaries, and others with a distinct muscular coat. The fenestrated membrane was broken through in many places, through which the new connective tissue blended with that in the middle coat, which had degenerated and was traversed with newly-formed vessels. The adventitia was thickened and likewise infiltrated with small cells. The upper portions of the vertebrals were in the same condition. The thrombosed parts of the vertebrals as well as the diseased internal cavities and sylvian arteries exhibited in spots a thickening of the intima, a formation of connective tissue in the place of the delicate endothelium, which, overlying this, was apparently in a state of proliferation.

The whitish-yellow spots in the cerebrum were cell-infiltrations, possibly the outcome of embolism.

The right facial nerve exhibited a greater infiltration of small cells than did the left one. In the liver was found great increase of the interstitial connective tissue.—*St. Louis Courier of Medicine;* from *Wien. Med. Woch.*, November 18, 1880.

Inoculability of Tuberculosis.—Dr. W. F. Whitney, in a paper read before the Suffolk County Medical Society of Massachusetts (*Boston Medical and Surgical Journal*, vol. cv., No. 4, 1881), says, "The conclusion which we are obliged to draw is that there is still uncertainty in the matter, considering that all the experimenters are not agreed in the results which they have reached. It is true that almost all have obtained an eruption of miliary bodies after injections, inhalation, and feeding with what was presumably tuberculous material; but the interpretation as to what these really were has differed with the experimenter,—the one side holding that they were simple inflammatory products, the other that they were true tubercles. Then, again, allowing that they are tubercles, is the tubercle the result of a specific process, or is it simply one of the expressions of inflammation that may arise as the result of various irritants?

"Taken by themselves, the latest experiments of Cohnheim, Tappeiner, and Orth, who are perhaps the more worthy of belief in that they have been able to avoid some of the errors of the earlier investigators, seem to point clearly to the fact that tuberculosis is an acute infectious disease; and Klebs has proposed for the nodules of syphilis, glanders, and tuberculosis the name of infectious tumors rather than that of granulation tumors, under which name they have been associated together by Virchow on account of their histological character; and Cohnheim has gone so far as to propose as a test for tubercle, not its histological structure, nor its peculiar ar-

rangement of cells of varying size, without vessels and with a tendency to cheesy degeneration, but its capability of inoculation.

"But, whatever may be the opinion of individuals, the mass of scientists have a right to demand more and clear proof; and it may confidently be expected, with the light thrown upon the subject already, that within the next five or ten years sufficient proof will be furnished to prove or disprove the question.

"So much for the scientific aspect of the question; and while we are waiting for this solution of the subject, there are hints thrown out in these experiments which may serve as guides in practice. It is with this in view that I have brought the experiments before you according to the ways in which the substance has been introduced into the body, and these, as you remember, are by direct inoculation, as food, and by inhalation. The first need not detain us. As to the second, there is little danger of directly eating tubercle, it is true, but there is a disease of cattle which has only very slight anatomical differences from, and is believed by the greater part of observers to be identical with, human tuberculosis; and if the results obtained by certain experimenters are verified, it does not require a very acute mind to see the danger of infection that is run by all of us, but especially by children. Our present state of knowledge does not warrant us in getting up a popular excitement or scare on the subject, but it behooves us as physicians to thoroughly investigate the source of supply when we place a patient upon milk diet, and, above all, when we wish that a weakly child should have the milk of one cow, be sure that that cow is healthy.

"The other possibility of infection lies in the atmosphere in the neighborhood of tuberculous patients becoming charged with particles by their expirations and coughing. And, knowing how utterly powerless we are to cure the disease when once established, we should impress upon those in close attendance upon the sick person the necessity of holding their breath when duty or affection brings them into close proximity to the face of the sufferer, especially during the act of coughing; also the great desirability of keeping a strong solution of carbolic acid or thymol in the vessels used for the reception of sputa from such patients, especially in hospitals, where the patients had perhaps best be kept in a separate ward."

THE ACTION AND USES OF CITRATE OF CAFFEIN. — Dr. Brackenridge (*Edinburgh Medical Journal*, August, 1881), in an article on this subject, gives the following conclusions regarding the employment of citrate of caffein:

1. In cases in which the renal glandular epithelium is diseased, is already doing a maximum amount of work, or is exhausted, this drug is unsuitable and should not be administered. 2. During recovery from acute desquamative nephritis, when renewal of the renal epithelium has reached a certain point, citrate of caffein cautiously administered has appeared to me to have had a decidedly beneficial effect; possibly, in such cases, it may exert a trophic as well as a secretory stimulant influence. 3. In such cases, as the arterial blood-pressure is tolerably normal, citrate of caffein should be given alone, not in combination with a vascular diuretic. 4. In cases of cardiac disease, with absence of compensation, and resulting diminution in the blood-pressure and flow of blood through the kidney, general dropsy, and transference of work in the kidney from the filtering to the secreting structures, a vascular diuretic, such as digitalis, must be employed in the first place to restore those conditions in the kidney which are essential to the action of citrate of caffein. For this purpose digitalis should be administered for a short period—one to three or four days—before commencing the citrate of caffein. 5. Citrate of caffein employed in this manner in conjunction with digitalis—which, for obvious reasons, must not be discontinued when the caffein is commenced—is a diuretic of extraordinary power, acts with great rapidity, and is especially valuable in this respect, that it causes a great increase in the elimination of urea (and probably of other solids) as well as of water. 6. It must, however, be remembered that special and powerful stimulation of any gland, especially if it be in a state of malnutrition, may, and usually does, lead sooner or later to exhaustion, and must therefore be regarded as at best a temporary expedient and of limited duration. 7. For this reason very large doses of citrate of caffein should be avoided. He has found gr. iii, administered once, twice, or three times daily, according to the circumstances of the case, amply sufficient for all purposes. 8. Whenever the beneficial effects of the drug have been attained, we should at once endeavor to render them permanent by suitable diet, well-selected chalybeate and other tonic remedies, or other remedial measures indicated by the special circumstances of the case. 9. Finally, in cases of very great ascites, in which the blood-pressure in and the flow of urine through the kidneys is interfered with by pressure on the kidney and the renal artery and vein, and in which the pressure of the urine within the capsules is increased by pressure on the ureters, neither vascular nor secretory diuretics, alone or combined, can act efficiently until the pressure of the ascitic fluid has been got rid of. 10. The citrate of caffein may be administered either in pill or in solution.

A CASE OF HYPODERMIC INJECTION IN NÆVUS.—Dr. S. Hudson says, "I observed a short article in the last number of the *Recorder*, from a correspondent of the *British Medical Journal*, on the danger of hypoder-

mic injections of tincture of iron in nævus. I, too, have had some experience in the use of injections in nævus, though not with the iron. About three years ago Mr. T., a young man about twenty years of age, came to my office and showed me a small warty excrescence on the end of his left index finger. He informed me that at times it bled profusely, and desired me to take it off. Without further examination or thought, I took my hypodermic syringe with a strong solution of nitrate of silver—perhaps three or four drops—and injected it into the nævus. In less than five minutes he was suffering the most intense pain and agony; his hand and arm up to his elbow became white and cold; and for three hours we labored constantly, rubbing and bathing it in hot cloths. I finally succeeded in quieting him with morphine, and his father took him home. The next morning I had the mortification to see that two of his fingers were dead—the first and second—to the second joint, and I feared from his appearance that he would lose his arm, if not his life. We did all we could in order to restore the warmth and color to his hand, but all to no purpose, for in less than a week the index finger (in which I inserted the solution) and the next one to it were black and dry as far up as the second joint, and his suffering for ten days was terrible. In eight weeks a line of demarcation commenced forming, and I had the *pleasure* of amputating the poor boy's fingers just above the second joint.

"I censured, reproached, and cursed myself and everybody else. Others had used hypodermic injections in nævus; I had used them before, with no unpleasant results; and why all this trouble? I could readily understand what was the cause of such unpleasant results. The solution had entered a small blood-vessel, producing coagulation and thrombus, but it was too late to remedy my mistake. The community, I can assure you, gave me no credit for the matter, and the friends of the boy were advised to prosecute me.

"The hypodermic syringe is a great favorite with me, but I do not believe I shall ever use it again in nævus with a solution of nitrate of silver or tincture of iron."—*Ohio Medical Journal.*

Congestion of the Lungs in Sunstroke.—Dr. G. Harrison Younge (*British Medical Journal*, vol. i., 1881, p. 881) has no doubt that the congestion of the lungs observed in sunstroke results from paralysis of the pneumogastric nerves, at the same time that there is irritation of the sympathetic, and, moreover, that death is in a great measure due to these lesions. The symptoms that point to this are occipital headache, difficulty of deglutition, oppressed and labored breathing, tumultuous action of the heart, rapid full pulse, and nausea, with endeavors to vomit. On post-mortem examination, the heart is found rigid and firmly contracted, the arteries are empty, while the venous system is overloaded, and the lungs are gorged with blood and more or less œdematous. If this condition is contrasted with the post-mortem appearances in cases where division of the pneumogastric nerve has occurred, a striking analogy will be seen between them. The probability of the symptoms above detailed being due to paralysis of the pneumogastrics is further increased by the fact that the sun exerts its principal influence on the medulla oblongata, and that in these cases there is always more or less evidence of paralysis of the other nerves arising from this part of the brain. Dr. Younge thinks death due in a great measure to the same cause, though, of course, the increase of temperature has much to do with it. He suggests stimulation of the pneumogastric nerves by electricity as a part of the treatment in sunstroke.

Carbolic Acid.—M. Lucas-Championnière (*Chirurgie Antiseptique*, etc., 2me éd., Paris, 1880) endorses Nussbaum's suggestion to rub the hands with a mixture of one part of crystallized carbolic acid and nine parts of vaseline before beginning an operation that is to be conducted under the spray, in order to avoid the unpleasant effect of the spray upon the hands.

The same author (quoted in *Union Médicale*, February 20, 1881) recommends the following formula for an antiseptic solution, in which the odor of carbolic acid is mitigated: Crystallized carbolic acid, 50 parts; thymol, 1 part; glycerin, 50 parts; water, 1000 parts.

Guénot (*Concours Médicale*, May 21, 1881) relates a case of facial erysipelas and one of malignant pustule in which signal benefit followed injections of a two-per-cent. solution of carbolic acid into and around the inflamed parts. Sixteen drops of the solution were injected at each puncture, of which five were made in the one case and seven in the other.

The *Canadian Journal of Medical Science* for May, 1881, gives the following formula for an improved styptic: Collodion, 100 parts; carbolic acid, 10 parts; tannin, 5 parts; benzoic acid (from the gum), 5 parts. Mix the ingredients in the order here written until perfect solution is effected. The preparation has a brown color, and on evaporation leaves a firmly adherent pellicle. It instantly coagulates blood, forming a consistent clot, and a wound rapidly cicatrizes under its protection.

Naso-Cranial Osteitis.—Prof. Fournier, in a lecture on the syphilitic form of this affection, thus concludes:

"1. If, in the great majority of cases, syphilitic nasal osteitis creates no danger to life, there is, nevertheless, one kind which is an exception to the rule. This kind is osteitis of the roof of the nasal fossa (*naso-cranial osteitis*), which owes its dangerous character entirely to its locality.

"2. The danger of this naso-cranial osteitis is a tendency to irradiate towards the organs

contained in the skull, the transmission being anatomically propagated by various lesions, the most common and principal ones of which are meningitis, encephalitis, and abscess of the brain.

"3. Clinically, these cerebral complications present themselves under two forms:

a'. A chronic form, characterized by vague symptoms of encephalitis, slowly progressive, with sudden and apoplectiform termination.

b'. An acute form, characterized by symptoms of an incomplete, irregular encephalitis, which becomes rapidly mortal.

4. It is not rare for these cerebral complications to remain absolutely latent, in a clinical sense, and terminate in an unexpected manner by a sudden death of a fulminating character."—*St. Louis Medical and Surgical Journal;* from "*Annales des Maladies de l'Oreille,*" etc.

Periods of Incubation of the Communicable Diseases.—Dr. B. W. Richardson gives a list of twenty-five communicable diseases which have a period of incubation. He adds a list of eleven diseases concerning which it cannot be said certainly that they have a period of incubation. These latter are: catarrh, puerperal fever, pyæmia, hospital gangrene, sloughing phagedæna, phagedæna, remittent fever, intermittent fever, choleraic diarrhœa, cerebro-spinal fever, carbuncle.

The diseases attended with stages of incubation are conveniently divided into five groups:

Shortest.—Incubation one to four days: Malignant cholera, malignant pustule, plague, catarrh, dissection wound diseases.

Short.—Incubation two to six days: Scarlet fever, rosalia idiopathica, diphtheria, dengue, erysipelas, yellow fever, pyæmia, influenza, pertussis, glanders, farcy, grease, croup, puerperal fever.

Medium.—Incubation five to eight days: Relapsing fever, gonorrhœa, vaccinia, inoculated variola.

Long.—Incubation ten to fifteen days: Smallpox, varicella, measles, rötheln, typhus, typhoid, mumps, malarial fever.

Longest.—Incubation forty days or more: Syphilis, hydrophobia.

Exophthalmic Goitre treated by Quebracho. — The patient was a woman, thirty-seven years of age, of neurotic temperament, and suffering from menstrual derangement. Dr. Draper remarked that organic lesions of the heart were frequently diagnosed in Graves's disease when only functional derangement exists. Where moral causes, grief, disappointment, shock, are at the root of the evil, time was the great restorer. Exophthalmic goitre dependent upon anæmia, chlorosis, menstrual trouble, dyspepsia, or glycosuria, demanded treatment directed to the conditions with which it was associated. This patient was put upon iron in the form of a carbonate, digitalis, and the alkalies. Rest was imperative. Patients of this class were liable to congestion, epistaxis, and œdema of the lungs, under an exaggeration of the original neuroses. This woman had an attack of pulmonary œdema, which was associated with exaggerated resonance and an entire absence of moist râles. She was relieved by the use of quebracho, morphine, nitrite of amyl, and local remedies. Two weeks later the patient had so far improved, under the use of iron and cardiac stimulants, that she was able to walk about the wards. Dr. Draper has employed the iodide of potassium under similar circumstances, with gratifying results in a few cases. (New York Hospital.) —*New York Medical Record.*

Belladonna and Arsenic in the Sickness of Pregnancy.—Dr. W. Macfie Campbell writes to the *British Medical Journal* (vol. i., 1881, p. 881) a case of distressing and rebellious vomiting in pregnancy where two minims of tincture of belladonna in a drachm of water, given every hour, put an end to the trouble completely. In another case, in a young lady, where an attack of acute ovaritis was followed by general peritonitis, several days' incessant retching had reduced the patient so greatly that collapse was hourly expected. Five minims of the tincture of belladonna in water were given every hour until six doses had been taken. On the doctor's next visit he learned that his patient had vomited only twice; and that symptom never returned.

Dr. John Warren (*New York Medical Record*) says that he has found Fowler's solution, given in drop doses on an empty stomach, comes nearer a specific for this affection than any other remedy. After it has been continued some time, benefit comes from suspending it in favor of nitro-muriatic acid with tincture of nux vomica, especially if anorexia exist or there is inactivity of the liver or kidneys.

Cysts of the Cervix Uteri filled with Air.—At a recent meeting of the New York Obstetrical Society, Dr. T. A. Emmet narrated a case as follows. A patient, upon whom Dr. J. R. Ripley had operated for a deep laceration of the cervix some months ago, had returned to him recently, and, on making an examination, he detected with the finger a number of supposed cysts on the cervix. When he punctured one of them, it was found to be distended with air, which escaped with an explosive sound like that from suddenly crushing an inflated paper bag. Dr. Emmet had been shown the case by Dr. Ripley, and he found a number of such air-sacs, varying in size from that of a millet-seed to one as large as a cherry-stone. He had seen reported somewhere one or two instances of like collections of air in the vaginal tissue, but never in the cervix. He supposed they were originally ordinary cysts, the

contents of which had undergone decomposition in some way and left the sac distended with air. He asked if any of the members present had seen such or the report of a similar case. Dr. Noeggerath and Dr. Thomas replied in the negative.—*New York Medical Journal*, July, 1881.

Composition of Jaborandi.—A new preparation of jaborandi has been introduced in Italy under the name of *pilocarpina sciropposa pura*, which, dissolved in water and applied to the eyes, will cause myosis, which ceases after an hour, when mydriasis will follow and last for twenty-four to sixty hours. Pure pilocarpin and its salts are said to never produce this secondary mydriasis in any dose. Taking a quantity of this preparation and adding a little hydrochloric acid, Dr. Albertoni found that most of the substance crystallized. These crystals, being separated and washed with ether, produced myosis only. The non-crystallizable portion, being also applied to the eye, caused mydriasis, resembling in a general way the effects of atropia, and not those of pilocarpin. This new product he calls *anti-pilocarpin* (*Medical Times and Gazette;* from *Gior. della Saluta*).—*New Remedies*, April, 1881.

Polyuria Syphilitica. — According to Prof. Semmola, there exists a new form of cerebral syphilis, the symptom of which is polyuria. Prof. Semmola has observed three cases. One of the patients observed, within twenty-four hours, excreted forty-three litres of urine, the specific gravity averaging between 1001 and 1003. All the curative remedies which were given proved not only unavailable, but even increased the symptoms, until he found traces of an old constitutional syphilis. Recognizing that a syphilitic process may have developed upon the floor of the fourth ventricle, reproducing pathologically the physiological experiments made by Claude Bernard, he submitted the patient to hypodermic injections of the albuminate of mercury and to the internal use of the iodide of potassium. The cure was effected within two months.—*Courrier Méd. Gaz. des Hôp.* (*Exchange*).

Atropia in Visceral Hemorrhage. — Tacke (*Berliner Klinische Wochenschrift*, 1881, No. 6; quoted in *London Medical Record*, April, 1881), having injected sulphate of atropia subcutaneously for eczema in a female patient ($\frac{1}{200}$ grain twice daily for two days), noticed that the menses, which had been very profuse, became moderate and remained so. The same result he has seen follow five times in two other patients, and in a case of hemorrhage from the lungs the hemorrhage twice ceased immediately on the injection. He holds that as a remedy for visceral hemorrhage it is preferable to extract of ergot (1) on account of its certainty and (2) because, in the strength used by him (about $\frac{2}{5}$ grain to an ounce of distilled water), it does not cause the inflammation which almost invariably follows the subcutaneous injection of extract of ergot.—*New York Medical Journal*, July, 1881.

The Administration of Purgatives by Hypodermic Injection. — Much attention has been directed in Germany and Italy to finding some means of replacing tartar emetic, ipecacuanha, and saline and vegetable purgatives of all kinds, by simple hypodermic injections of apomorphia and aloin (the alkaloid of Socotrine aloes). Just as with a subcutaneous injection of apomorphia effects of nausea and vomiting have been obtained, so with a warm aqueous solution of aloin ($\frac{1}{25}$) injected in the thigh or forearm there have soon been produced true symptoms of purgation. In these cases the remedy does not act by direct contact with the gastro-intestinal mucous membrane. These, as the *Paris Médical* says, are very singular facts, which call for serious study and verification.—*Medical Press and Circular.*

Antiseptic Inhalations in Pulmonary Phthisis.—Dr. Coghill (*Practitioner;* from *British Medical Journal*, May 28, 1881) recommends the following formula in phthisis when the purulent stage is coming on. It is also useful in the purulent expectoration accompanying pneumonia, in the profuse expectoration of purulent bronchitis, as also in bronchial asthma.

℞ Tinct. iodini etherealis,
Acidi carbolici, āā ʒij;
Creasoti, vel thymoli, ʒj;
Alcoholis ad ʒi.—M.

Patients, while using this form of inhalation, frequently experience great relief from the aches and flying muscular pains which often occasion much distress in the advanced stages of phthisis.

Inunction as a Remedy for Local Inflammation.—Dr. Edward T. Williams, in a letter to the *Boston Medical and Surgical Journal*, highly recommends the old-fashioned remedy of applying oil or grease externally for acute inflammations. He has used it for years, and finds it a very efficient substitute for a poultice. In almost all forms of acute inflammation of the thoracic and abdominal viscera, also in inflammatory sore throat, abscesses, and some cutaneous eruptions, it is very valuable. He generally orders lard,—which is to be found in every household,—simply rubbed upon the skin and covered over with a piece of flannel. If a stimulating effect is wanted, he adds a little salt, when the mixture answers as well as camphorated oil.—*New York Medical Record.*

Hamamelis Virginica as a Local Application. — Mr. Netherclift (*British Medical Journal*, June 18, 1881) uses an extract of hamamelis called "hazelin" as an application to irritable and inflamed piles at the margin of the anus. He bathes the anus with the solution three or four times a day,

while a piece of lint dipped in it is kept applied to the anus during the intervals. All urgent symptoms, as a rule, pass away in from twelve to twenty-four hours. In chronic and intractable ulcers of the varicose or eczematous description, excellent results have been afforded by using the "hazelin" (probably the same as our "Pond's extract") after the fashion of a water-dressing.

EUCALYPTUS GLOBULUS AS AN ANTISEPTIC DRESSING.—Prof. Lister (*Practitioner;* from *Lancet*, May 21, 1881) believes the oil of eucalyptus to be a perfectly trustworthy antiseptic, while free from the toxic or locally irritant effects of carbolic acid. Dammar varnish holds the oil in combination and prevents its too ready evaporation. Gauze impregnated with this mixture and paraffin has been prepared, and is in appearance and feel exactly like carbolated gauze, while it is unlike it in having an agreeable aromatic odor.

THE BROMIDES IN RELATION TO TRAVELLING.—Dr. E. J. Tilt (*British Medical Journal*, vol. ii., 1881, p. 11) says that he has often enabled nervous and delicate women to travel long distances with comfort by telling them to take twenty-five grains of bromide of potassium, dissolved in a wineglassful of cold water, on going to bed, after travelling all day. A good night has enabled most of them to continue their journey the next day and on the following day by taking the same dose of the bromide on each successive night.

TREATMENT OF IMPETIGO "LARVALIS" BY IODOFORM.—Mr. Balmanno Squire (*British Medical Journal*, vol. i., 1881, p. 767) softens and removes the scabs by bathing them in warm water and soap, then dries the surface gently and dusts on a powder of equal parts of iodoform and starch (later iodoform alone), covers this with a layer of glycerin laid on with a camel's-hair brush, and repeats the operation every few hours. Rapid cure ensues.

ADMINISTRATION OF IODIDE OF POTASSIUM.—A good way to administer the iodide of potassium, says Dr. Webster, is in the form of a saturated solution, the dose being five drops in a little water three times a day after eating. The quantity should be increased to the extent of from one to three drops with each succeeding dose. One minim holds about a grain of the drug.—*New York Medical Record.*

TINCTURA FERRI CHLORIDI.—Dr. H. Hagar recommends that tincture of chloride of iron be mixed with simple syrup and then with milk, this mixture not affecting the teeth nor the usual styptic taste being apparent.—*Druggists' Circular.*

ANTISEPTIC VACCINATION.—E. F. Green (*Lancet*) suggests the use of carbolic spray during vaccination and the hermetic covering of the wound afterwards.

MISCELLANY.

SEA-AIR AND INFANTILE DIARRHŒA.—The Sea-Shore Home has just issued its annual report for 1880. Dr. Edward T. Williams, the physician in charge of the Home for several years, thus sums up his experience:

"1. Sea-air is *not* an infallible cure for infantile diarrhœa. Some cases will die under the best management.

"2. The vast majority of cases get well, if removed early and properly fed and cared for.

"3. After decided collapse and head-symptoms come on, death is the rule, recovery the fortunate exception.

"4. Bronchial and pulmonary complications are usually aggravated by the cold air.

"5. Not a few cases are made worse by exposure in stormy weather and the cold nights of the last of August and September; at these times both fires and extra clothing are needed, and some take cold in spite of them. Indeed, it has seemed to me that the autumnal diarrhœas are chiefly caused by cold and are unsuited for the sea-side."—*New York Medical Record.*

CASE OF POISONING BY BITTER ALMONDS.—A man thirty-eight years of age, having eaten nothing through the day, swallowed two handfuls of bitter almonds and a pint of beer. He shortly fell insensible, and when seen a little later by Dr. Green, of the Charing Cross Hospital, was collapsed, with gasping and labored breathing, cyanotic, with a hardly perceptible pulse, rapid and flickering, some dark mucus about his mouth; his jaws were fixed, teeth firmly clinched, pupils closed and perfectly insensible to light and touch, fæces passed involuntarily. The stomach-pump was used, and about a pint of thick brown fluid, containing a quantity of small white particles smelling strongly of hydrocyanic acid, was removed. The stomach was washed out, the battery used to resuscitate the nearly dead patient, and hot applications were made to the extremities. Later, inhalations of strong spirit of hartshorn were employed. The patient recovered.—*Medical Times and Gazette*, vol. i., 1881, p. 38.

READY METHOD OF PREPARING FOMENTATIONS.—Take your flannel, folded to the required thickness and size, dampened quite perceptibly with water, but not enough to drip, and place it between the folds of a large newspaper, having the edges of the paper lap well over the cloth, so as to give no vent to the steam. Thus prepared, lay it on the heated surface of the stove or register, and in a moment steam is generated from the under surface and has permeated the whole cloth sufficiently to heat it to the required temperature. This method is often very convenient and efficient where there is no opportunity to heat much water at a time.—*Michigan Medical News.*

THE REPORTING FIEND AGAIN.—Dr. John Ashhurst, of Philadelphia, in referring to some typographical errors in a recent report of his clinical lecture in the *New York Medical Record*, writes, "I wish to protest that I do *not* use, in gonorrhœa, injections of SIX OUNCES of acetate of lead to TWO OUNCES of water, nor do I attempt to cure CHANCRE with camphor and opium suppositories. I think *two scruples* to *six fluidounces* quite strong enough for the injection; and it is *chordee*, not chancre, the pains of which I attempt to relieve by the rectal administration of anodynes."

FLOWERY!—This is the way they begin the notes of cases in North Carolina: "Miss N. P., aged 19 years, of a nervo-sanguine temperament, with a heredity to melancholia on the father's side, a well-developed brunette, highly educated, wealthy, having been granted all the luxuries that fond and doting parents could give in an élite society, and adorned with all the graces that beauty and chastity [*sic*] could confer on the female. Menstruation began at fifteen years of age," etc., etc.

OBITUARY.—Dr. George Rolleston, Linacre Professor of Physiology in the University of Oxford, died on June 16 last, at the early age of fifty-one. His most widely known work is that on "The Forms of Animal Life."

ALLOCHEIRA is the name applied by Prof. Obermeister to the subjective error of locating an impression on the opposite side of the body to that where it is applied. Several cases are related of this curious affection. In one the man had syphilis, in another he had received an injury of the spine. In all cases the sensibility, as tested by the æsthesiometer, was normal.—*New York Medical Record.*

NOTES AND QUERIES.

IN Dr. J. H. Musser's remarks on primary cancer of the gall-bladder, in the *Times* for August 13 (p. 731), a transposition occurs which mars the sense. Under the microscopic appearances, the sentence should read, "Transposition from the catarrhal to the cancerous process," etc.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM AUGUST 21 TO SEPTEMBER 3, 1881.

WEBSTER, WARREN, MAJOR AND SURGEON.—Granted leave of absence for twenty days. S. O. 149, Department of the East, August 24, 1881.

MCCLELLAN, ELY, MAJOR AND SURGEON.—Relieved from duty in the Department of the Columbia, and to proceed to Louisville, Ky., and report by letter, upon his arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

WOODHULL, A. A., MAJOR AND SURGEON.—Relieved from duty in the Department of California, and to proceed to New York City and report by letter, upon his arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

BROWN, HARVEY E., MAJOR AND SURGEON.—Relieved from duty in the Department of Texas, and to proceed to New York City and report by letter, upon his arrival there, to the Surgeon-General. S. O. 192, A. G. O., August 22, 1881.

HUBBARD, VAN BUREN, MAJOR AND SURGEON.—The leave of absence granted him in S. O. 169, A. G. O., August 26, 1881, is extended eight months, with permission to go beyond sea. S. O. 193, A. G. O., August 23, 1881.

COUES, E., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for one month, to take effect when relieved by a medical officer, with permission to apply for three months' extension. S. O. 97, Department of Arizona, August 22, 1881.

BYRNE, CHAS. C., MAJOR AND SURGEON.—Relieved from duty at Angel Island, Cal., and assigned to duty as Post-Surgeon at Benicia Arsenal and Attending Surgeon at Benicia Barracks, Cal. S. O. 142, Military Division of the Pacific and Department of California, August 23, 1881.

DICKSON, J. M., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty in the Department of the Columbia, and to proceed to New York City and report by letter, upon arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

KING, WM. H., CAPTAIN AND ASSISTANT-SURGEON.—To accompany Battery "I," Third Battery, to Yorktown, Va., and remain with it until further orders. S. O. 153, Department of the East, August 31, 1881.

WHITE, R. H., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for twenty days from 5th instant. S. O. 125, Department of West Point, September 2, 1881.

COWDREY, S. G., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty in the Department of the Platte, and to proceed to New York City and report by letter, upon arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

ADAIR, GEORGE W., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for two months. S. O. 196, A. G. O., August 26, 1881.

SHANNON, W. C., CAPTAIN AND ASSISTANT-SURGEON.—Relieved from duty at Fort D. A. Russell, Wyoming, and assigned to duty as Post-Surgeon at Fort Thornburgh (junction of White and Green Rivers), Utah. S. O. 81, Department of the Platte, August 22, 1881.

GARDNER, E. F., CAPTAIN AND ASSISTANT-SURGEON.—Upon being relieved by Assistant-Surgeon Bushnell, is relieved from duty in Department of Dakota, and will comply with Paragraph 3, S. O. 171, A. G. O. S. O. 150, Department of Dakota, August 17, 1881.

ROBINSON, SAMUEL Q., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Relieved from duty in the Department of Dakota, and to proceed to Boston, Mass., and report by letter, upon arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

POWELL, J. L., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Granted leave of absence for one month, to take effect as soon as the Medical Director of the department shall have completed certain inspection duty at Fort Stockton, Texas. S. O. 99, Department of Texas, August 13, 1881.

STRONG, N., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—To proceed to Park City, Utah, report for temporary duty to Commanding Officer of the troops *en route* to Fort Thornburgh, Utah, and remain on such duty until arrival of Capt. W. C. Shannon, Assistant-Surgeon, U.S. Army. S. O. 84, Department of the Platte, August 29, 1881.

ARTHUR, W. H., FIRST-LIEUTENANT AND ASSISTANT-SURGEON.—Granted leave of absence for one month, to take effect from the date of return of Surgeon Forwood to Fort Omaha. S. O. 82, Department of the Platte, August 21, 1881.

BUSHNELL, G. E., ASSISTANT-SURGEON.—Relieved from temporary duty at Fort A. Lincoln, D.T., to take effect on his arrival at that post, and to proceed to Fort Ellis, M.T., and report to the Commanding Officer for duty at that post, to relieve Assistant-Surgeon E. F. Gardner. S. O. 150, Department of Dakota, August 17, 1881.

PHILADELPHIA, SEPTEMBER 24, 1881.

ORIGINAL LECTURES.

CLINICAL LECTURE ON CONGENITAL SYPHILIS.

BY PROF. JOHN A. LARRABEE, M.D.,
Hospital College of Medicine, Louisville.
Reported by A. H. KELCH, M.D.

GENTLEMEN,—I find to-day in the waiting-room an infant, aged six months, whose disease presents a fruitful theme for our discussion. It is a case of congenital syphilis. I do not propose, however, to go again over the ground of the various manifestations of syphilis in the child: these have been dwelt upon at sufficient length in my previous lectures. Moreover, in the surgical clinic you have become familiar with the unsightly sores, the primary and secondary manifestations, the deformities and paralyses which follow in the course of this terrible scourge in the adult. You have observed the success with which the primary and secondary manifestations have been treated, and no doubt you have placed opposite the names in your notes an asterisk pointing to a foot-note which reads, "cured."

You have been taught to look upon the period of childhood as typical of purity no less than of innocence. How instinctively do we recoil from the thought of a loathsome disease in the precincts of the nursery! Childhood is the greenhouse of human life,—the garden in which, nurtured by paternal care and warmed by filial affection, the tendrils which bind us to earth are put forth, and the tender buds of infancy unfold into rosy childhood life. But, alas! there are slugs in our finest roses,—there are worms at the root. The time has been when men, like the giant oaks, grew white with the frosts of many winters, and even in the period of decay were monuments of physical integrity. The men who die at the top are growing less, while the bald head and wrinkled features are noticed on younger shoulders. What is the matter? If you will excuse the expression, they are dying not from the top but at the root.

As practitioners in the field of infancy and childhood, we are gleaners: we see the stubble after the grain is cut, we see the imperfection of boasted cures in the weakened offspring.

The period of latency is often called a cure.

The time will come when your voices as physicians will be more potent to preserve the nation's integrity than the voices of senators. Wholesome regulation of matrimonial union will eventually force its way into legislative halls, for nations have been weakened and rendered impotent by syphilis. Let us, then, consider the case before us in regard rather to its practical bearing and interest to us as the child's physician, than as a useless discussion of certain theories which, if established, have no influence in arresting the progress of the disease. It is enough for us to know that at some very remote period of the history of our old planet a poison was poured from the phial of God's wrath which, like the subtile poison poured into the ear of the Danish king, has distilled its leprous dew through countless generations.

Into the palaces of the rich, into the hovels of the poor, into the families of crowned heads and those of abject slaves, it makes its way, for no wealth or poverty hath control over the passions of the human soul.

Protean in its manifestations, ever assuming a different form, never wearing the same countenance twice, and always present for evil, you will recognize how necessary it must be to keep always on the alert that you may detect it in all its varied forms.

A review of the cases presented at this clinic in the last seven years, gentlemen, will prove the statement that two-thirds of the children brought here in that time have shown the syphilitic cachexia. That is a sad commentary, gentlemen, on the virtue of our people; but it is nevertheless true. When you go out into the practice of medicine you will find that a large number of your little patients possess the cachexia which is here presented to-day.

At this stage of your studies it is not necessary that I should portray for you the various manifestations of the different forms of this disease in the order in which they occur. It is perhaps necessary and best that I should give you some idea of the probable forms you will meet. Preparatory to doing so, let me say I would have you, in the first place, sceptical—entirely so—as to any history that may

be given you by the patients or their friends in this matter. Now, see what we have here,—this prematurely senile, little old man, with shrivelled limbs and stunted growth, with a pale, sallow, anæmic countenance. I tell you, gentlemen, phenomenal manifestations are worth more than all the histories ever gotten by interrogation. They must not be entirely unheeded, however. You will have cases put to you in this manner: you will be told that a marriage has taken place, and that in a reasonable time afterwards conception has occurred, and you, perhaps, are consulted on account of some of the little troubles that arise in the course of this interesting period. You congratulate the parents on this happy culmination of affairs, but, behold, about the third month you are called to conduct an abortion. In the space of the same year you are called to attend a miscarriage, No. 2. You are called in the second year to attend a premature birth, No. 3. Next you are called to the patient at full term to deliver a child that dies!

Wherever you have such a history, such a chain of circumstances, let it at once arouse your suspicions of syphilis; and, while you medicate the mother and seal your mouth, remember you are fighting the syphilitic dyscrasia. It is an unusual thing for abortion to occur unless brought about by this cause or by another which it is here unnecessary to name. It is the earliest manifestation which will attract your attention, and it points to syphilis before birth. Next comes syphilis after birth; now it may make its appearance in various forms or stages. The case before us is one of syphilis manifesting itself in six weeks after birth. From previous experience I am confident, although I have not talked with this mother, that she will recognize the truth of the statements I am about to make. "Madam, this child was born full and plump?" Yes, sir. "But it had sore eyes?" Yes, sir. "Which by improper treatment has left one eye sightless?" Yes, sir. "Then it took a bad cold and never got well?" Yes, sir. "Then your child had an eruption?" Yes, sir. "It still has some of this eruption upon it where it first made its appearance?" Yes, sir.

Now, gentlemen, if all these other symptoms were absent from this case except this single ecthymatous pustule, I would say, syphilis,—syphilis in the tertiary stage. It was primary in the father of this child. The mother, as mothers generally are, is entirely innocent. The father here communicated syphilis to his offspring in the very act of procreation. Thus syphilis has been carried in this mother's womb during all the period of gestation. Do you suppose she has escaped this ordeal unscathed? No, indeed. In the third month of pregnancy this woman had sore throat; mucous patches, then in regular order the other manifestations of the disease, made their appearance. Inoculated into the ovum at the moment of conception, the disease had stamped its mark upon the fœtus, and all but destroyed the child.

Thus you perceive here one of the manifestations of syphilis; but these are not the only manifestations. This case, unrecognized, might have gone on until caries of the bones occurred, until the nasal septum was destroyed; and let me warn you, gentlemen, where these manifestations of a persistent disease of mysterious character occur in a child, watch it closely, and when there appears the development of an ecthymatous pustule or intertrigo, then treat the case as a case of syphilis, and see how many times your suspicions will be confirmed by the results of treatment. The first symptom generally is restlessness, and this precedes the eruptive stage; the infant is never still, it is constantly in motion except when asleep, and it sleeps in the daytime and cries all night. It suffers the torture of pain which it cannot express.

How old must the child be before you can dismiss from your mind the idea of inherited syphilis? I answer, As old as Methuselah. The manifestations of the disease may appear at birth, at the fifth year, in adult life, at any time along the road. But take this as a rule, the later the manifestation the milder the cachexia.

Before these external manifestations appear, the oculist may look into the eyes and detect there the characteristic signs of its presence. The dentist, as he extracts affected teeth, sees the serrated edges of the incisors, and looks back into childhood and says, This is syphilis; and thus I might go on, gentlemen, until the hour had passed, enumerating the channels leading to the discovery of this cachexia; but the object of my lecture will have been obtained, which is to impress upon you, once and last, the necessity for keen and careful examination in infantile dis-

eases that do not readily admit of classification. Having made the diagnosis in this case, our minds are settled as to its cause. I have not inquired into the family history. I do not care to. I know I am correct. The proof of the pudding is in the eating; the confirmation of my assertions is to be found in the results of treatment.

That treatment shall be mercury and iodide of potassium. Specific diseases require specific treatment; and let me impress you with the fact that the best way to give mercury is to rub it in. If you give it by the mouth, in a few days you must stop on account of its effects upon the bowels; but rub it in, and you will soon be gratified to see these manifestations disappear like snow before a summer sun. The ecthymatous pustule will leave a mucous scar, the child will sleep all night and all day, and finally this will cease. Then is the syphilis cured? No. Then how long will you treat a case of this kind? Not long at a time, but you will watch it and treat it occasionally when the manifestations appear, for, I was about to say, during a natural lifetime. You are never to let such a case pass out of your observation.

What else shall you do? Nothing. This treatment will be successful if properly pursued. Therefore, we close to-day one of the most important subjects it were possible to bring before you.

ORIGINAL COMMUNICATIONS.

A CASE OF CANCER OF THE PANCREAS WITH SECONDARY DEPOSIT IN THE LIVER.

BY J. M. ANDERS, M.D.

MR. J. G., æt. 56, a saw-maker, had been ill four months before coming under my care. He stated that there was no traceable hereditary taint. His illness began with eructations and other dyspeptic symptoms associated with flatulence and constipation. About two months later (or two months before I saw him) he experienced pain in the epigastric region, which gradually increased as the case progressed, and a little later jaundice appeared rather suddenly, which remained permanent. When first seen by me (November 19, 1880) there was intense jaundice, marked emaciation and weakness, and severe pain in the epigastric and right hypochondriac regions, coursing downward toward the right groin and upward to the shoulder, and frequently around the body laterally to the back. The pain was of a stabbing character. There was nausea, but no vomiting; the mouth was parched, tongue dry and heavily coated with grayish-yellow fur; appetite poor; bowels loose, from four to six passages daily; stools light in color, containing considerable ropy mucus, and there was entire absence of biliary coloring-matter. Upon physical examination of the abdomen, I found slight tympany, with a great deal of gurgling. Liver-dulness extended about half an inch below the costal border, and in the region of the gall-bladder a small, smooth tumor could be felt on palpation, reaching about one and a half inches below the normal limit of liver-dulness. This at the time was regarded as a distended gall-bladder. No nodulation of the liver could now be detected. There was marked tenderness over the epigastric region, strongly suggesting the presence of local peritonitis. The most active remedies failed to stimulate the liver to secretion or to change the color of the alvine evacuations, and anodynes failed to afford relief from the intense suffering. As time went on, the whole aspect of the case grew worse, the pain, weakness, and emaciation becoming more pronounced.

February 1, the tumor referred to had become larger and more superficial, extending about two and a half inches below the ribs. It was firm to the touch, but scarcely at all nodular. The following phenomenon was observed in this connection: with the patient lying on his back and breathing naturally, the walls of the abdomen were seen to glide over this tumor, which was stationary, upward during inspiration and downward during expiration. A small nodule could now be felt about the middle of the left lobe of the liver. The patient was at this period sent to Tacony to live with a daughter, and I did not again see him until May 20, when I was called. At that time he was so reduced in strength as scarcely to be able to sit up in bed, and his general condition indicated approaching dissolution. The only change in the abdominal signs was a slight increase in the size of the tumor, which was still perfectly fixed, and the walls of the belly during inspiration glided over it, as before described. It was found that even forced breathing did not in the slightest degree influence the site of the growth. Death occurred June 10, 1881.

The autopsy was made thirty-six hours after death, Drs. William R. Cruice and Markwardt being present. The body was extremely emaciated. Heart and lungs normal in appearance, except colored with bile; pleura non-adherent. Spleen healthy-looking. The stomach was collapsed, and its coats natural, except a few patches of velvety redness of the mucous lining near the pyloric extremity. There was evidence of chronic peritonitis, particularly of the gastro-hepatic omentum. Coils of intestines free. Kidneys about normal in size; the right, however, was

engorged with venous blood. Capsule not adherent. The liver was slightly enlarged, and its parenchyma intensely stained with bile; capsule normal. On the under surface of the left lobe, at the anterior border, there was a small cancerous nodule; the right lobe showed half a dozen similar nodules, about the size of an English walnut, and extending along its under surface near its anterior edge.

The biliary ducts were all obliterated, and not even a trace of the ductus communis could be found. The gall-bladder, however, was about normal. The tumor, which had been felt through the walls of the abdomen, proved to be the head of the pancreas, which was the seat of cancerous change and was greatly enlarged, being at least three times its natural size, coming forward beyond the lower border of the liver, and extending to the right to the middle of the right lobe of the liver. Its consistence was only moderately firm, and in spots very friable. It was nowhere adherent. Body of pancreas somewhat enlarged, but free from cancer. Duct patulous.

Remarks.—Judging from the extraordinary size of the head of the pancreas and the amount of change there found, and from the fact that so few cancerous nodules were found in the liver and none at all in other organs, it is probable that the pancreas was affected primarily. The circumstance that the head of the pancreas attained such enormous dimensions without involving the duodenum or other adjacent organs by contiguity deserves note. It is generally held at the present day that the pancreatic secretion moistens and liquefies the contents of the bowels. The view doubtless receives confirmation from the present case, since it will be remembered that the pancreatic duct was patulous, and the body of the gland enlarged or tumefied, but apparently free from carcinoma: hence under these circumstances there probably was an abundant secretion of pancreatic juice, producing the looseness of the bowels. Physiologists agree that the bile is the chief natural laxative in health; but perhaps this teaching will need to be somewhat modified when we arrive at a further state of knowledge in regard to the action of the pancreatic secretion on the bowels and their contents.

One reason for reporting the present case is to show that the diagnosis of cancer of the pancreas is sometimes a difficult task. Some writers, among them Da Costa, think the disease can always be distinguished. The cardinal symptoms, according to these writers, are constipation, nausea, vomiting, and pain. But, as will have been observed in our patient's case, there was diarrhœa during nearly the entire course of the disease, and at no time was there vomiting.* In addition to these deviations from the general rule, the implication of the liver and the interference with its functions rendered a positive diagnosis during life almost out of the question. As a diagnostic sign, however, the immobility of the tumor already referred to deserves special prominence as excluding distention of the gall-bladder or growths of the liver and parietes; but this symptom could only be of service in thin subjects and with a tumor of considerable size.

THE LOCATION OF BULLETS BY ELECTRICITY.

BY H. NICHOLS WADSWORTH, D.D.S.,
Washington, D.C.

I DESIRE to put on record a discovery made in 1875, by which lead can be located in a living human subject by means of electricity. I quote from my article of that date, forwarded for publication to Dr. J. W. White, editor of the *Dental Cosmos*, of Philadelphia, the receipt of which he acknowledged under date of June 14, 1875, which letter of acknowledgment now lies before me; also the letter of acknowledgment of Dr. J. B. Hunter, of the New York *Medical Journal*, dated June 12, 1875, which letter acknowledging the receipt of my article also lies before me.

"I have discovered by a series of experiments with the electro-magnetic battery that a current of electricity thrown through the human living body gives rise to great uneasiness when passing through lead, amounting to absolute pain if the power of the battery is increased and the current through the lead is continued any length of time.

"Having in my profession but limited means of verifying or extending the experiments upon this most interesting subject, it must be left for extension in the hands of the surgeon, who so frequently probes in vain for the leaden messenger of death,—to the surgeon, whose field of observation is so much more extended, and who has the material for experiment so much more abundant."

* Authors disagree as to the proportion of cases in which there is vomiting.

Wardell (Reynolds's System of Medicine, p. 421) states that diarrhœa is present in about one-third of the cases.

The above extracts from my articles, with the date, and the date of the editors' replies, are evidence of the time of the discovery, and its presentation to medicine and surgery.

My first experiments were upon my own person, having had the misfortune to receive a full charge of shot from a friend's gun, whilst woodcock-shooting. Each pole of the battery should have a wet sponge attached. Placing one pole at the base of the brain, or base of the spinal column, a distinct feeling of uneasiness is experienced when the other pole is placed so as to pass the magnetic current of electricity through the lead, and this uneasiness is quickly rendered decidedly painful if the current is continued long and increased in power, although that increased power will give no uneasiness when applied on other parts of the body.

My second series of experiments were made upon an old soldier, kindly sent to me by Dr. Norris, U.S.A. This ball was lodged four or five inches from the spinal column, and a little below the fifth rib, as near as I can remember, and could be felt with the hand. Mr. McGill says, "The feeling was of a stinging character," and when a stronger current was passed through the lead "caused me to jump in my chair."

My third experiment was with Colonel Morrow, U.S.A., of Gen. Sherman's staff.

Dr. Basil Norris, Surgeon U.S.A., says of the ball in Colonel Morrow's case, "The point of entrance of the ball was near the groin; the current located it on the inner aspect of the thigh near the knee."

Colonel Morrow says, "I am satisfied your location is a correct one."

My fourth experiment was on John Tehan, at the Soldiers' Home, by courtesy of Dr. Huntington, U.S.A., in charge. "The ball in this case," says Dr. Norris, "entered about the centre of the right gluteal region; the current located the ball near the hip-joint." Mr. Tehan says, "You found the most painful point in your experiment on me."

In the second and the fourth or last case the current was longer continued and the power of the battery increased so as to prove beyond a doubt the presence of the lead; the patients being strong men. Dr. Norris says, "Your experiments with the electro-magnetic current to find a bullet lodged in the living body—as witnessed by me—were successful in defining a painful or burning sensation supposed to be produced by the presence of the ball."

Dr. D. L. Huntington, Surgeon U.S.A., and acting-surgeon in charge of the Soldiers' Home, through whose courtesy I performed the experiment at Soldiers' Home Hospital in presence of himself and Dr. Norris, says, "I have no hesitation in saying that I think your experiments on August 7, on the person of Tehan, an inmate of the Home, demonstrated the presence of a metallic body at or about the region between the greater trochanter of the right femur and the tuberosity of the ischium." "The presence of this body was repeatedly evidenced by a sharp pricking pain, with some shock, when the magnetic current was made to traverse the region; similar effects were not produced under similar manipulations on other regions."

In all these experiments the lead was encysted, the wounds having occurred more than twenty years previous to this date.

In recent wounds I have no doubt the most gentle current would indicate the presence of lead, and with a little care the location could in most cases be reduced to the diameter of one inch, which would be sufficiently accurate for the surgeon's purpose.

Having obtained a pretty accurate knowledge of the location by the experiments, the poles of the battery should be brought as near the lead as possible, and the current thrown through it in as direct a line as possible.

ACUTE POISONING BY ALCOHOL.

BY J. H. MUSSER, M.D.

J. S., æt. 4 years, white, male; mother keeps a small grog-shop. At 4 P.M. on the 27th of July of this year she found her little son behind the bar, draining a tumbler of its contents. At once she saw that he had taken whisky of an uncertain quantity, though not less than two ounces. In fifteen minutes he was stupid, and in fifteen more he was unconscious. According to a neighbor's statement, at 6 P.M. "he was like death,"—pale and cold, with a cold, clammy perspiration on face and body, with an excessively frequent and very feeble pulse, and breathing heavily.

He was placed in a hot mustard-bath and rubbed with whisky. Reaction set in in an hour. Not regaining consciousness, however, I was sent for.

I saw him at 11 P.M., in the following condition. Skin hot, dry, red; extremities warm; temperature, 102½°; respiration, 44, not stertorous; pulse, 140, quick and small; completely unconscious, conjunctivæ insensible, pupils contracted and insensible to light; general anæsthesia. After considerable effort emesis was brought about; food and a large quantity of a pink-colored mucus and fluid were discharged. The breath and the vomited matter were of a strong alcoholic odor. After vomiting he could be slightly aroused, but consciousness returned gradually, and he did not recognize his mother until 6 A.M. of the next day. That day, a foul tongue, no appetite, and an irritable temper were the only symptoms noted.

From what I subsequently learned, the boy took fully four ounces of spirit. The case illustrates the law that liquors are more readily borne in early than in later life. It is sad to relate that not only has the boy a nervous system that can bear the blows of stimulants, but also one that craves them. About a year previous to this occurrence he took, clandestinely, sufficient liquor to stupefy him for some time. Often he has been tipsy. While attending his mother in illness, when the boy was but three years old, I was horrified to find him smoking a cigar, the strength of which would have made me succumb. Smoking is a daily luxury with him. When one considers the character of the whisky and cigars kept at these corner grog-shops, to express surprise is mild exclamation.

TINCTURE OF CONVALLARIA IN PAROXYSMAL CARDIAC PALPITATION.—Semonowski reports a case of nervous paroxysmal palpitation of the heart, associated with pain radiating into the left arm, occurring in a pale, nervous woman of thirty years. All kinds of remedies had been employed without benefit, until Botkin advised the administration of tinct. convallariæ majalis, in ten-drop doses, four times a day. In the course of a week all the subjective symptoms had subsided, while a previously demonstrable moderate dilatation of the right ventricle and of the left auricle diminished so far as to leave only slight dulness on percussion in the upper part of the left parasternal line.—*St. Petersburger Medicinische Wochenschrift*, May 7, 1881; *New York Medical Record.*

NOTES OF HOSPITAL PRACTICE.

EPISCOPAL HOSPITAL.

CLINICAL SERVICE OF DR. LOUIS STARR.

Reported by CHARLES M. SELTZER, M.D., Ex-Resident Physician.

PROGRESSIVE PERNICIOUS ANÆMIA—TRANSFUSION PERFORMED—BLOOD-CELLS COUNTED WITH THE HÆMACYTOMETER.

AS long as the origin of the blood-corpuscles remains mystified in theories and ill-defined facts, so long will our knowledge of diseases of the blood remain incomplete, and our treatment unsatisfactory or else of no avail. The case about to be related is especially interesting on account of the numerous and combined causative agencies, and the completeness of the clinical features.

On September 15, 1880, G. C., Irish, laborer, æt. 40 years, was admitted to the Episcopal Hospital, said to be suffering with chronic diarrhœa. His former illnesses were bronchitis and diarrhœa while in the army in 1864, and intermittent fever contracted in the swamps of North Carolina about the same time: the latter continued at intervals until about three years ago. He had had gonorrhœa, but no history of syphilis could be obtained. He had been employed for a long time in lead-works, but had never had any signs of poisoning.

The onset of his present illness was dated back two years, at which time he began to feel weak and languid and had to pass his urine frequently and in small quantities. Thirteen weeks before admission diarrhœa commenced, and it continued with increased severity, so that when first seen he was profoundly anæmic; the countenance pale and with a slightly yellow tinge; conjunctivæ pearly; tissues generally flabby; slight œdema of legs and feet; tongue thick, flabby, and coated; bowels very loose, the passages being light yellow, thin, and containing some white flakes. There was no vomiting or cough, but there was great prostration. A more minute physical examination showed the lungs healthy; the apex-beat of heart in normal position, with some irregularity, an apex systolic murmur, heard also at base and in the axillary line; increased dulness in liver and splenic regions; some pain in the lower part of the abdomen; urine of light-yellow color, sp. gr. 1012, no albumen or

sugar. The blood was examined with Dr. Gowers's modified hæmacytometer, the result being: number of red corpuscles per cm., 745,000; number of white corpuscles per cm., 5000.

After this detailed examination the case was diagnosed one of progressive pernicious anæmia. His treatment was quinine, iron, and punch by the mouth, and opium by the rectum, upon which he seemed to improve until September 19, when he had severe pain in the abdomen, followed by short attacks of diarrhœa, and on September 25 the diarrhœa became continuous. The blood-count at this date was: number of red corpuscles per cm., 755,000.

September 29.—Had a slight chill in the morning; the respirations became rapid; vomited several times. Dulness not nearly so marked in the splenic region, but the liver-dulness about the same.

September 30.—Vomiting and diarrhœa continue; passages contain shreds of mucus, and are greenish yellow. Bismuth. subcarb. gr. xx and pulv. ipecac. gr. iij every three hours, and an ounce of lime-water to every three ounces of milk, were ordered, and the former treatment stopped.

October 1.—Vomiting, diarrhœa, and pain in the lower part of the abdomen almost continuous. Sodii bicarb. gr. x, instead of the pulv. ipecac., were added to the bismuth; a cantharidal blister was placed on his epigastrium and afterwards dressed with morph. sulph.; milk f℥ij and lime-water f℥i were given every two hours, alternately with milk punch f℥ij.

October 4.—Vomiting checked for the past two days. Has had a very constant and annoying hiccough since yesterday.

October 7.—Became mildly delirious; diarrhœa and vomiting returned, and a few ecchymotic spots appeared. The hiccough was stopped by hypodermic injections of morphia and atropia.

October 9.—Had some coffee-grounds vomiting. Blood-count showed 785,000 red corpuscles per cm., 9000 white corpuscles per cm.

It was decided to perform transfusion, and accordingly at noon Drs. Charles T. Hunter and J. H. Packard injected f℥vss of defibrinated human blood into the left median basilic vein. The patient seemed cold afterwards, but soon warmed up and felt more cheerful. A blood-count showed 1,245,000 red corpuscles per cm., 6500 white corpuscles per cm.

During the afternoon his respirations became more difficult, and his pulse very feeble. Tinct. digitalis ♏ x were given hypodermically, and ammon. carb. gr. x every two hours by the mouth; hot water and whisky were substituted for the milk punch, which made him sick at his stomach. He sank into a wandering delirium during the night, from which he rallied slightly after hypodermic injections of ether.

October 10.—Death took place at noon, just twenty-three hours after transfusion.

The temperature during the last three weeks was normal in the morning, and usually rose two degrees in the evening, until the last two days of life, when it fell slightly below normal. The pulse ranged wildly and irregularly between 84 and 112, being slightly accelerated in the evenings.

Autopsy.—Body much emaciated; subcutaneous adipose tissue scanty.

Brain.—Marked sub-arachnoid effusion, greatest over convexity posteriorly. Vessels at base empty. Brain-tissue anæmic, very few vascular points to be seen on section. Lateral ventricles empty.

Lungs.—Left: numerous fine, readily broken-down bands of plastic adhesion at apex and over posterior and lateral surfaces; lower lobe somewhat congested and œdematous.

Right: a few ounces of serum in pleural sac; a few isolated bands of pleuritic adhesions; upper and middle lobe œdematous, lower lobe quite congested and very œdematous.

Heart.—Flabby; valves normal; small ante-mortem clot in the right ventricle.

Liver.—Normal.

Spleen.—Slightly more firm than usual; adherent at several points to the left abdominal wall, and the capsule thickened at these points.

Pancreas.—More firm than normal; at several points over its surface minute white marks were seen about as large as pins' heads.

Kidneys and Supra-renal Capsules.—Normal.

Intestinal Canal.—Stomach: mucous membrane thickened, much congested near pyloric orifice; over remainder of mucous membrane there were several isolated patches of ecchymosis. Large

and small intestines reduced at least one-third in calibre. The mucous membrane of small intestines appeared to be thin; the glands of Peyer were ill developed, and small isolated patches of ecchymosis were observed.

The mesenteric glands were smaller than usual. The mesentery was loaded with fat, the quantity of fat being much greater than in the subcutaneous areolar tissue.

The following is the report of microscopical examination made by Dr. J. H. C. Simes:

The portion of the bone medulla removed from the shaft of the humerus is of a dark-red color and soft consistence. From a microscopic examination it is found to consist entirely of cells: no fibrous tissue in any appreciable amount could be detected. Neither fat-vesicles nor fat-drops are present. The cells vary in size from $\frac{1}{3500}$ of an inch to $\frac{1}{500}$ of an inch and even larger. Many of the smaller elements are free nuclei, made evident by carmine-staining; others show the characteristics of lymph cells or white blood-corpuscles; others, having the same size as the latter or somewhat larger, are nucleated, the nucleus placed nearer the periphery rather than in the centre of the protoplasm, and the latter is slightly colored yellow; these cells possess all the appearances of nucleated red corpuscles of fœtal blood; others contain a nucleus relatively small to the amount of protoplasm—epithelioid in type; and, finally, large nucleated masses of protoplasm—myeloplaxes.

A section of the small intestines and of a mesenteric gland were examined microscopically: they presented no marked abnormal change. The heart and liver were normal. The spleen contained an increased amount of fibrous and connective tissue.

In the etiology of this disease especial interest has of late years been centred in the changed condition of the alimentary tract. From an elaborate study of three cases, Pepper* has concluded that the primary and essential lesion appears to be an affection of the chief blood-making tissues, spleen, lymphatic glands, marrow of the bones, causing defective elaboration of the blood; and although this may be true in some cases, yet in others one is inclined to make them of secondary consideration to the thickened and congested condition of the mucous membrane of the stomach, and the marked atrophy of the intestines and mesenteric glands, which supply ample cause for the gradual but fatal inanition. Fenwick† gives some very interesting cases in which atrophic changes in the alimentary tract alone were causes of fatal anæmia; and when we bear in mind that both the quantity and the quality of the blood depend mainly upon the quantity of nutriment dissolved and absorbed by the digestive tract, we have quite a comprehensive view of cause and effect in these cases. These atrophic changes seem to have been the most destructive in the foregoing case. Doubtless the irregular attacks of intermittent fever extending over twelve years constituted an active element in the downward course of the patient; but, as there were no acute symptoms of the disease itself within the last three years, but a minor portion of the cause can be assigned to it.

Workers in lead frequently present themselves as marked cases of anæmia, and they may continue to a fatal termination; but the absence of the blue line on the gums or of localized paralysis left but slight suspicion of this cause in the foregoing case.

When used by a competent person, the hæmacytometer is very accurate and satisfactory in diagnosing and noting the progress of these cases. Six months previous to this case the lowest blood-count on record was made on a similar patient in the same hospital, there being but 525,000 red corpuscles per cm.‡

LOUISVILLE CITY HOSPITAL.

CLINICAL SERVICE OF WILLIAM H. WATHEN, M.D., OF THE KENTUCKY SCHOOL OF MEDICINE.

Reported by A. H. Kelch, M.D.

LACERATION OF THE CERVIX UTERI.

(Continued from page 621.)

GENTLEMEN,—At the conclusion of my last lecture I was speaking of the treatment of laceration of the cervix when this condition is detected immediately after its occurrence. The purport of all

treatment is the union of the lacerated edges; but in the event the woman continues to suffer, and the uterus fails to undergo the process of involution, the probabilities are that the union is not complete, and that her condition will not be benefited by anything short of another operation, and by the proper steps she may be entirely cured. Yet too much has been expected of this operation, and too little attention has been paid to the method of performing it, and to the preparatory treatment: hence the objections that have been urged by some writers. Every case of laceration of the cervix is benefited by preparatory treatment, and especially those cases where there has been extensive cellulitis or peritonitis, for so long as there remain any inflammatory deposits or adhesions binding the uterus down, an operation will most certainly fail to do any good, and will be pretty sure to re-establish the original inflammation. The enlarged uterus, by traction on the connective tissue, so obstructs the circulation as to cause congestion not only of the organ itself but also of the surrounding tissues.

The patient's general health should be well attended to, and if there is a tendency to constipation give general laxatives containing small doses of aloes to stimulate the torpid circulation in the pelvic organs. To give tone to the vessels and relieve the congestion, inject a gallon of hot water into the vagina twice a day until all tenderness on pressure against the vaginal roof or uterus has disappeared. This may be hastened by the frequent application of iodine, or an occasional blister upon the abdomen over this region. If the previous inflammation has shortened either broad ligament, the weight of the uterus will be thrown upon it when the woman assumes the erect posture, and this as a source of irritation frequently keeps up an old cellulitis. This is best relieved by a lever pessary. If the pessary causes pain where it comes in contact with the thickened broad ligament, it may be narrowed at that part sufficiently to relieve pressure. If the lever pessary cannot be worn, some other form that will support the uterus or not cause pain may be tried. It is customary before introducing the pessary to antevert the uterus, but this is unnecessary, as the uterus can be more easily and with less injury anteverted by means of the pessary itself. It should be so shaped as to hold the uterus in this position, and by this means the lips will be kept together and a source of irritation removed. If the perineum is lacerated, the pessary must be held in position by a T bandage.

If the parts are so tender that a hard pessary cannot be worn, the lips may be kept together by introducing a pledget of cotton wet in glycerin or bromo-chloralum in front of and behind them, or by an inflated india-rubber ring pessary, which, if introduced with the uterus anteverted, will hold the lips together.

In addition to this treatment, erosion or ulceration should be treated with local applications twice a week, such as Churchill's tincture of iodine, carbolic acid, or some astringent or weak caustic. If the granulations bleed freely when touched, it is well to apply occasionally Monsel's solution of persulphate of iron. Before making any such application, the lips should always be well closed, and it is best to put the woman in the horizontal position for some hours afterwards. If she cannot remain in bed, it is a good plan to antevert the uterus and hold the lips together by forcing a pledget of cotton against the anterior lip. Sometimes in double laceration there is a cicatricial band around the cervix, which, if associated with cystic degeneration of the mucous follicles, nearly strangulates the lips and causes a condition similar to paraphimosis. This condition must be relieved by puncturing the cysts with a lance-shaped knife, by stabs in every direction over the whole of the everted surfaces, followed by a thorough application of Churchill's tincture of iodine. This treatment should be repeated every week until the lips are reduced nearly to their proper size and all erosion has about healed. If these precautions be taken, and the operation be properly performed after the different sources of irritation have been removed, the involution will be rapid, and the woman will regain her usual good health.

Before beginning the operation, inject a gallon of hot water into the vagina, which will contract the blood-vessels and prevent profuse hemorrhage. Place your patient on her left side, or on her back, and expose the cervix with a Sims speculum. Dr. Emmet has devised a uterine tourniquet to enclose the cervix above the laceration to

prevent hemorrhage, but the previous injection of the hot water will make it unnecessary to use this instrument unless the cervix is very soft, in which case there is a greater tendency to bleeding. If there has been no cellulitis, the cervix may be drawn down near the vulva; but otherwise it would be a dangerous practice. In the first instance have an assistant to bring the lips together with tenacula, and denude the surfaces on each side of where you intend to make the external os; then introduce a strong iron or silver wire through both lips, on each side, by which the assistant may pull the cervix low in the vagina and hold it while you denude the parts down to the forks of the laceration. You can use the knife or scissors, but where there is a tendency to hemorrhage I prefer the knife, as it makes a smooth cut surface and permits more perfect union by adhesion. When the rent extends to or above the vaginal junction be careful to denude the fork of it superficially, or you may divide the circular artery. If the hemorrhage is profuse, and cannot be arrested by the application of ice or the injection of hot water, it can be partially controlled by traction upon a suture introduced under the base of the rent, or completely so by uniting the suture. Always denude the under side first, so that the blood will not obscure the view. The undenuded portions on each lip should widen gradually from the uterine canal towards the external os, and when brought together they should correspond. This will make a new canal through the cervix, trumpet-shaped, but, as the diminution in size is greater in the neck than in the body, this new canal will become of uniform diameter.

The width of the undenuded surfaces must be in proportion to the amount of hypertrophy, and, since the enlargement is greater at the ends of the lips than at the bottom of the laceration, the canal must necessarily be trumpet-shaped.

If in a double laceration the effort of nature to fill up the fissure by granulation has caused the rent to be filled with a dense cicatricial plug, which prevents perfect apposition of the edges or interferes with healthy circulation, it should be dissected out to its base in a V-shaped piece. Again, if the rupture of cysts along the mucous membrane of the canal or on the vaginal surface causes contraction and converts the former flat edges of the flaps into convex surfaces that cannot be brought into close contact, they must be shaved down until coaptation can be made perfect. It is even sometimes better to partially excavate the projecting surface, so that the sides of the flaps may be put in perfect contact when the sutures are united. When the cervix is lacerated in two or three or more sections, the operation of denuding each cleft and uniting the flaps together would often result in failure, as the traction in opposite directions would cause the sutures to cut out, and the uneven development of the flaps makes it difficult to coapt the surfaces properly. In the bifid form, if we cut out a V-shaped segment and bring the freshened surfaces together, the cervix and canal will be restored to normal size. If the cervix is lacerated into three or more sections, the operation of cutting out a segment on each side and uniting the edges as in double laceration will generally be successful.

The most difficult part of the operation is thought to be the introduction of the sutures. If the tissues are soft, the best needle is a round one, which makes an opening but little larger than the suture and causes no hemorrhage; but where the tissues are indurated, Sims's lance-pointed needle is less likely to break and can be introduced more easily. From two to four silver sutures should be introduced deeply on each side through both lips and united by twisting on the pressure of a shot. The denuded edges should be perfectly approximated, and the sutures should not be drawn too tightly, or they will strangulate the parts and cut out. If there is much hemorrhage, the first suture should be introduced into the tissue beneath the fork of the rent. The sutures must be introduced upon both sides before uniting any of them. There is occasionally hemorrhage from the track of the suture, which can be promptly arrested by the injection of hot water or a saturated solution of alum. It is more difficult to operate on a laceration of one side than upon both, for the reason that it is troublesome to denude the angle and free it from cicatricial tissue: however, if the flaps are held apart by an assistant with a double tenaculum, the obstacles may be to some extent overcome.

The after-treatment consists in keeping the woman in bed for two weeks and in drawing the water for a few days. It may then be passed on the bedpan, or, better, on the hands and knees, in order that

urine may not get into the vagina and come in contact with the cervix. The diet should be nutritious and easily digested, and the bowels be allowed to move daily. After the second day the vagina should be washed out daily, morning and night, with tepid water, preferably carbolized. The sutures should be removed from the seventh to the tenth day. Great care must be exercised in withdrawing them, lest the delicate union between the edges be broken apart. It is best to remove the suture nearest the vaginal junction first; and if the union is not complete, the others may be left in a few days, until the ununited portion may heal by granulation.

The uterus, which should always be anteverted before the operation, will generally remain so while the woman is in bed; and if it tends to become retroverted when she gets up, it should be held in position by the proper pessary, but it must not be so large as the one used before the operation. If this is not attended to, the traction on the lips of the vaginal walls may separate the united edges and reproduce the original trouble. If the vagina is abnormally enlarged or the perineum ruptured, an operation for the relief of these conditions should be performed as soon as the patient has sufficiently regained her health and other circumstances will admit of it.

TRANSLATIONS.

Gangrene of the Skin of Trophic Origin.—At a recent meeting of the Société de Biologie (*Le Progrès Médical*, 1881, p. 385), MM. Leloir and Dejerine showed a patient suffering from a peculiar affection so rare in France that no previous case has been reported. It was that of a young girl born of nervous stock, her mother being neuropathic and a sister choreic. Three years previously she had begun to display, without previous cause so far as known, patches of superficial gangrene on the cheeks; the eschars separated, and were followed by linear cicatrices in which keloid developed. During three years similar patches showed themselves on the trunk and on the arms. The lesions first manifested themselves with a pricking sensation, a little redness, and a notable diminution of sensibility at the affected point. Within nine hours a whitish patch, not preceded by a phlyctena, formed, and this went on to superficial sphacelation. Later it became brown, detached at its edges, thrown off, and gave place to ulceration, and finally to a cicatrix, when the anæsthesia which had been observable about the borders disappeared. Every fifteen days a fresh eruption of patches occurred. For three weeks previous to the presentation of the patient she had been taking atropia and chloride of gold under Dr. Vulpian's direction, and her condition seemed to be improving.

Treatment of Chorea by Arsenic.—M. Siridey (*La France Médicale*, 1881, p. 782) has used this remedy for a long time. He employs the *liqueur de Boudin*, which is nothing more than a solution made by boiling for a quarter of an hour one part of arsenious acid in one thousand parts of water. The dose varies, of course, according to age. For a child from six to ten years of age, the following formula may be employed:

℞ Boudin's solution, gr. x ad xij,
Syrupi acaciæ, ʒij.—M.

This dose should be taken so frequently that two fluidounces are ingested in the course of twenty-four hours.

By this method complete tolerance is established; but, as the disease is only brought under control when the system is saturated with arsenic, the daily amount of Boudin's solution should be increased by about half a drachm daily until nausea, vomiting, and diarrhœa show themselves. The use of the solution is then suspended for a while, and then recommenced, but with longer intervals. It is at this point in the treatment that the muscular contractions cease. A cure is generally obtained in four to five days; rarely a week is required; M. Siridey has observed it on the third day. The dose of the medicine is then gradually diminished. It suffices to maintain the condition of nausea a single day in order to obtain a definitive cure.

Hydrops Articulorum Intermittens.—Pierson (*Deutsche Med. Wochens.*, 1881, No. 13; *Cbl. f. Chir.*) gives the case of a child, eleven years of age, who had suffered during two years with a swelling of the various joints, appearing suddenly and without regular type. The intervals were at first of several weeks' duration, but gradually became shorter, while the attacks were of longer duration. Exceptionally two joints suffered at once, and even the

ankle- and wrist-joints. The child was otherwise well nourished, always free of fever, the general condition only affected by pain. In contrast to the sudden appearance of the enlargement was its gradual diminution. Electro-cutaneous sensibility over the affected joints was markedly increased, while in acute articular rheumatism this is diminished. The galvanic current alone gave relief. Arsenic was given at the same time.

NOTE ON A PECULIAR PLEURITIC FREMITUS AS A DIAGNOSTIC SIGN OF PULMONARY AFFECTIONS OF AN ARTHRITIC CHARACTER. —At a recent meeting of the Académie de Médecine (*Bull. de l'Acad. de Méd.*, June, 1881) M. E. Collin read a paper on this subject, written by M. Woillez. The author, after speaking of recorded instances of pulmonary complications with arthritic affections, goes on to fill up a gap left by previous authors, by describing a pleuritic rubbing which is a sign of pulmonary rheumatism. He tries to show that it is possible to diagnosticate any chance affection of the chest which may occur, not only during the rheumatismal pyrexia, but aside from any attack, in an individual suffering from the arthritic diathesis. He asserts that the lung is affected by the time the painful symptoms, though slight, are manifested in the shoulders or the upper extremities; and such is the diagnostic value of the sign which he attributes to rheumatism that he considers it the index of arthritism not only during the rheumatic pyrexia, but as a unique sign of rheumatism in patients previously exempt from any sign of the disease.

The sign is as follows. Imagine a perpendicular line drawn from the axilla to the base of the thoracic cavity. In this region, which is not always ausculted by physicians, there may be habitually heard, in pulmonary affections of an arthritic nature, at the junction of the middle and lower thirds, a sound which M. Collin has named "arthritic rubbing," and which resembles the crepitant râle of the first stage of pneumonia. It is only produced during the act of inspiration, and in order to be heard the act must at times be prolonged. It may be observed sometimes on both sides of the chest at once, at other times one and the other alternately, but in the majority of cases it is heard on the right side only. This sound is at first nothing more than a râle of pulmonary congestion of an arthritic character. It is not, in fact, says the reporter to the Academy, pleuritic at all. However, the sign appears to be of practical value, a careful examination of one hundred and forty-five arthritic patients having shown its presence. Whether it may not also occur without the presence of rheumatism is the question which is not yet decided. However, enough is known to make this auscultatory sign well worth the investigation of practical physicians.

A VASO-MOTOR NEUROSIS OF THE SKIN. —Appenrodt (*Deutsche Med. Wochens.*, 1880, No. 16; *Cbl. f. Chir.*) attended a thirteen-year-old boy, of scrofulous habit, but otherwise healthy, who in the space of two years suffered six attacks of a peculiar affection of the skin. This began as redness of the end of the nose, with pain. A few days later, after the exudation of slight moisture from the surface, three parallel longitudinal stripes, like excoriations, showed themselves. Others appeared later on the nose and eyelids. A few days afterwards half-dollar-sized patches appeared on both cheeks, presenting an erysipelatous appearance, with deep infiltration, on the surface of which little pearls of transudation showed themselves, looking like the lesions of eczema. The moisture soon dried up, leaving little crusts, and the entire eruption healed up without scaliness, though a certain amount of reddening of the skin, always worse on exposure to cold, remained.

Three or four attacks occurred in the year. The eruption resembled erysipelas, but was without fever. It also closely resembled exudative erythema, but its symmetry and its constant localization pointed to a vaso-motor origin. A factitious etiology was excluded. All medication remained without effect.

NITRE-PAPER IN ASTHMA.—Dr. William Murrell (*British Medical Journal*, June, 1881, p. 918) bears testimony to the great value of the fumes of nitre-paper, if properly prepared, in many cases of asthma. Pieces of white blotting-paper, six inches square, are saturated in a hot concentrated solution of chlorate and nitrate of potassium. Six of these pieces are laid one over the other, so as to form a thick tablet. Before quite dry, the pieces of paper may be individually sprinkled with Friar's balsam, camphor, or some other aromatic. When used, the tablet is to be folded like a book-cover, and placed on its edges on a plate, and then lighted.

MEDICAL TIMES.

PHILADELPHIA, SEPTEMBER 24, 1881.

EDITORIAL.

CURBSTONE DOCTORS.

THE ingenious journalistic mind has coined a word to describe the new species of medical man who has of late too prominently represented the profession in the eyes of the world, and has given the title "curbstone doctors" to the irresponsible individuals who have been ready with unasked advice for the treatment of the President's case, or who have published their "criticisms" of the medical attendants in the columns of the daily press. Like the financier who was found dead of starvation in a garret, with a "plan to extinguish the national debt" in his pocket, the curbstone practitioner is not unfrequently one whose abundant leisure and freedom from the pressure of personal practice permit him the opportunity to theorize on the President's case to the nearest reporter and to demonstrate the imbecility of the medical attendants and the futility of their fatuous efforts to prevent an intelligent community from understanding what every one but themselves must know, that they are all wrong,—wrong in diagnosis, wrong in treatment, wrong in prognosis,—and that the only thing to save the President's life is—to take the curbstone practitioner's advice.

Of a different sort is the curbstone practitioner whose standing in the community is good and whose fame or notoriety gives his expressions a certain value in the general opinion. The criticisms of such persons as they have appeared in the daily press can but be interpreted in one of two ways,—either as the product of an irresistible itch for notoriety which forces the critic to put himself forward on every public occasion, or, worse still, a venomous envy, hatred, and malice which makes the nation's calamity an excuse for an attack upon the object of its aversion.

The natural desire on the part of the community to possess not merely the facts relating to the case of the illustrious patient, but such comments, however little their worth in the absence of full and exact data, as may be furnished by editorial wisdom, has led many of our contemporaries, lay and medical, into the premature expression of opinions which perhaps, on reperusal at a later date, may give rise to retrospective qualms. Nothing can be lost, except on the part of the "curbstone doctors," by waiting until the history of the case is presented. As to the distinguished gentlemen in charge of the President's case, curbstone judgments, fortunately, do not give them much uneasiness. In the dignified words of one of their number, "the criticism to which the President's medical and surgical attendants have been subjected does not disturb their equanimity in the least. They have a responsible duty to perform. Nothing will be omitted, nothing knowingly committed, which in their judgment will endanger this valuable life, and, when the proper time arrives, they will submit the medical and surgical history of this remarkable injury to the profession, the only tribunal competent to pass an opinion on the conduct of the case."

CORRESPONDENCE.

THE ADIRONDACKS.

IN the editorial column of the *Philadelphia Public Ledger*, August 8, 1881, is an admirable article on "Camp Cures," in which it is stated that, owing to an enthusiastic recommendation of the Adirondacks as a cure for consumption, in an article entitled "Camp Lou," which appeared in the May number of *Harper's Magazine*, "great and sad caravans of sick people are to be met with at every turn on the Champlain boats and the

railways on the borders of the Adirondacks. Any and every sort of consumptives are going, regardless of the fact that not every sort of lung-trouble is benefited by the bracing, stimulating, almost congesting air of this great mountain park of New York." Though appearing as an editorial, it is evidently from a professional pen, and contains much that may profit both physician and patient.

I read this for the first time about a fortnight ago, in the very region referred to, and among many of these sad pilgrims. To "go to the Adirondacks" appeared to be the only direction that many of them had received; and here they were, hundreds of miles from their homes, drifting, as it were, without compass or captain, and some of them making sad shipwreck of the little that was left them of hope and of life.

With the Adirondack region I have been acquainted for many years, and since the summer of 1869 have made an annual visit to it. I know its value for the sick, as I know its abounding pleasures for the well; but I also know that to send every form and stage of lung-trouble there, without accurate and specific directions for the invalid, and without a personal knowledge of the region itself, is unwise, I had almost said, is cruel.

"Man may not live by bread alone;" and it is equally true that man, and especially a sick man, may not live by air alone. He must have not only good air, but good food; and it will greatly help him if, with these, he have about him good society also. And yet, as has been intimated, everywhere in this region this summer were to be found instances where attention to these essentials had been neglected. It is with the hope of preventing a recurrence of these disasters that this paper is written.

It is needless to give a detailed account of the situation and sanitary properties of the Adirondacks. These have been abundantly furnished by guide-books, and a medical paper on the subject may be found in vol. xv. of the *New York Medical Record*.

That for many forms of bronchial and pulmonary disease, for the early stages of phthisis, for men more advanced in this disease, who love an out-door life and the sports of the woods, much benefit may be obtained, cannot be questioned. The writer has now in his mind a lady sent by him to St. Regis in the summer of 1870,—a patient of the late Dr. Pepper, who was regarded by that accurate diagnostician as hopelessly ill,—who had at that time, with the ordinary rational symptoms of phthisis, the physical signs of dulness on percussion and coarse moist subclavicular râles, but who, from the first, derived advantage from a residence at St. Regis, and who, since that time an annual visitor there, is now apparently well, the physical signs having long since disappeared with her improved general condition. The late Dr. Ralph Townsend—then with extensive tuberculous softening—found great benefit from his life at St. Regis, and that life and the enjoyment of it were for some years prolonged by his visits there. One of the most remarkable instances of the good effects of this climate is that of Dr. Edward C. Trudeau, of New York, who left that city some years since, apparently a hopeless invalid, and who, after having lived for some years continuously at St. Regis and its vicinity, is now a type of vigorous and active manhood. But, it must be added, in these years there have been not a few who have come to St. Regis with bright hopes who have failed to find there the health they so earnestly sought.

I have named St. Regis first because it was in this immediate vicinity that "Camp Lou" was situated, and because "Paul Smith's" is named by the magazine-writer as the cure for consumption. At Paul Smith's the invalid has long had the best social and hygienic advantages to be found in any public house in the Adirondacks. Here may indeed be found good air, good food, and good society. And yet it is not every one with pulmonary disease who should go to St. Regis. In the first place, besides an hour by rail from Plattsburg, there is a drive of nearly forty miles by stage-coach, which, however easy it may be for the tourist, is a pretty hard day's work for the invalid.* This, however, may be greatly lightened of its fatigue by stopping for the night at "French's," about half-way in the journey, or, perhaps even better, by resting at Bloomingdale, about ten miles east of Paul Smith's. The road is not a rough one, but is rather monotonous and tiresome. Of late years "Paul Smith's" has become a favorite and fashionable hotel, and for many summers has been so crowded as to greatly tax its obliging manager to find room for the crowds who visit it. An invalid arriving without previous notice, and sometimes even with previous notice, may be compelled to put up with quarters which are unsuitable for him. The only way by which this can be surely avoided is to go there early in the season, say in June or July, before the tide of travel has set that way. With these precautions, I believe many sufferers from lung-disease may be greatly helped by a residence at St. Regis.

Near by—say less than half a day's journey—is the Prospect House, on Upper Saranac Lake. This is beautifully situated, commands a lovely lake and mountain view, has comfortable rooms and a good table. It is well known to some of our Philadelphia physicians, one of whom, at least, spends a part of each summer there.

From the Prospect House to Tupper's Lake a little steamer plies daily, and it is doubtful if in the whole Adirondack region there is a more beautiful sheet of water than this.

* The writer was told this summer that next year this stage-drive would be shortened to twenty-six miles.

"Mark Moody" has a plain and, for tourists, a comfortable house at one end of the lake; but it is scarcely comfortable enough for invalids. At the other end of Tupper's Lake is "McClure's" Hotel,—one of the best-kept houses in the woods. For tourists it is a very desirable place; but Tupper's Lake, when I last saw it, was not in telegraphic communication with the outer world, and to the sick man it seems to be very far from his home. And yet along its shores and in its vicinity there are now many Philadelphians in camp, some of whom have long been invalids.

Returning from Tupper's to Saranac Lake, we have Corey's,—a place at which I have never stopped for any length of time, but which I have always heard favorably spoken of. On "the carry" between the upper and the lower Saranac is Bartlett's, a plain but comfortable house, where I have always found a good table. Many who are slightly invalided spend summer after summer here, as they think, to their great benefit. The late Dr. Ely, of Rochester, was for more than twenty summers an annual guest here. The house itself would look more cheerful and attractive if a few coats of paint were put upon it. It is a less expensive place than the others I have named; and, while naming this, it would perhaps be as well to say that "going to the Adirondacks," with all that it implies,—the cost of the journey, the cost of a guide, his board and one's own, and many other incidental but necessary expenses,—cannot be done without considerable outlay: and yet I know no investment which pays so large a dividend—in health, enjoyment, in everything that one needs in his summer vacation—as this does.

Coming from Bartlett's to the lower Saranac, we reach Martin's (now Miller's),—a large house, and one much frequented. I have never liked this place. To me, as I think they would be to invalids, the immediate surroundings of the house are depressing. Perhaps by another year the new proprietor will have the place improved.

Lake Placid, which is about twelve miles from Miller's, or which may be reached directly from Westport, on Lake Champlain, by daily coach, is a beautiful lake with lofty mountains about it, their base seeming to rest in the lake itself. The atmosphere here, like that of the lakes we have mentioned, is highly invigorating, and the general effect of the place is certainly inspiriting. There are four public houses here, and I regard it as a desirable place for invalids, especially for those who do not wish to be far from the line of daily travel. I have had no occasion, in my frequent visits here, to complain, but I was assured by those who had been there this year that the tables generally were poor, which, if correct, is a suicidal policy on the part of the landlords which cannot too soon be corrected. A very pretty rustic house has been built on the lake, known playfully as "Castello Rustico." It is plain and rustic, and would hardly do for confirmed invalids; but for those but little ailing, and with cheerful companions, it would be, I think, a healthful and pleasant resort.

The entrance to Lake Placid from Lake Champlain is by way of Westport and Elizabethtown. This last-named place is itself a favorite with tourists and with some invalids. The rides and the drives about it are beautiful; but the town is a warm—I had almost said, a hot—one; too much so, I think, for invalids.

The coach from Elizabethtown passes through the town of Keene, from which a road carries the traveller into Keene Valley.

Keene Valley, or, as it is often called, Keene Flats, has long been a favorite resort for tourists and for invalids. With the former it must long remain so, for it is a lovely valley, with grand mountain scenery, and is the gate-way to the exquisitely beautiful Ausable Ponds. But my own experience of Keene Valley during the month of August, 1880, did not impress me favorably with it as a place for invalids. The air lacked the snap of Placid, the Saranacs, and St. Regis. In the middle of the day it was very hot, and there seemed to be no way of escaping from the sun's rays. I write this with regret; for the social life at Beede's, in Keene Valley, was of the most delightful character.

Returning to the main coach-route from Elizabethtown, the invalid bound for Placid or the Saranac will find much relief in stopping for the night at the comfortable inn at Edmonds Ponds. A night passed here will enable him to reach Placid or Saranac next day without fatigue.

With much of the region thus described the writer, as he has said, has been well acquainted for the last twelve years. Within a few weeks his steps have been turned in another direction, with an earnest desire to know how much the place might be suited to a class of patients in whom he has long had the deepest interest.

Blue Mountain Lake is a beautiful sheet of water in the southern part of the Adirondack country. To reach it the traveller leaves Saratoga at 9.40 A.M., on the Adirondack Railway, the present terminus of which—North Creek—is arrived at in about three hours. Here coaches and carriages on buckboard springs are in waiting, and a journey of about thirty miles, twenty of which are over an excellent road, has yet to be made. To the tourist this is altogether a pleasant journey, but to the invalid it may be one of great fatigue. Especially is this the case with the last ten miles, which are through a forest, and which are generally made after night sets in. The road is in some places rough, but the chief inconvenience is from the darkness and the dampness of the night journey.

Should it happen to rain, as often it does, these discomforts are greatly increased.*

All this may be obviated, and by the invalid must be obviated, by stopping for the night at "Jackson's," a comfortable inn twenty miles from North Creek and at the beginning of the Woods Road. Next morning the drive may be pleasantly made and without fatigue.

As has been said, Blue Mountain Lake is exquisitely beautiful, closely resembling the most beautiful of the Scottish lakes. Until this year there were but two public houses here. They are both prettily situated, but—and I write it with regret—neither of them seemed to me to be up to the standard which an invalid requires; and yet in both of them there were sick men and women, some of whom had travelled hundreds of miles to get there. In one of these houses the furniture, both of the parlor and the bedrooms, was cheerless and scanty; and I was assured by those who had been there that the table was a poor one. In the other, with much in it to recommend it, my own observation soon showed me that, although with perhaps but a little more effort it might be made so, as it then was its table was unsuited to an invalid's stomach. This was much to be regretted, for here were good air and good society. It may be that another year will give better food. Perhaps it will be said that the writer is fastidious in the matter of diet. He thinks not, but insists that the guest should at least have good, sweet bread, good butter (if possible), good, fresh sweet milk, good beef, and fresh-laid eggs. On this diet an invalid may thrive; without it the best air will prove of but little value.

On the opposite side of the lake, commanding a beautiful view from almost every one of its many windows, there has, this summer, been erected a large hotel, called the Prospect House. This is capable of accommodating several hundred guests, and will be furnished with all the modern improvements,—electric bells, electric lights, etc.; but, what is far more important, it has delightful rooms, most comfortable beds, and a good table. An immense piazza nearly encompasses the house, affording beautiful views of the lake. There is a large drawing-room, with smaller and pretty reading-rooms, in each of which, as night came on, there were large open wood fires burning in pretty and antique fireplaces. Here for nearly a fortnight the writer, with a medical friend from Philadelphia, was comfortably cared for, as were many others of his fellow-townsmen, and here an invalid may find the three requisites which have been so much insisted on,—good air, good food, and good society.

It would, however, be a mistake to suppose that even here a complete exemption is afforded from all ailments. Several of the guests complained of diarrhœa, which by some was referred to the drinking-water,—a matter which must be looked into. I was more disposed to regard it as due to the cold drive through the forest after night. A little good claret at dinner appeared, in most instances, to be all that was needed in the way of medication.

It would hardly be worth while to go so far for good air and good food were there no advantages to be found here which are not to be had nearer home; but that there are many such advantages I do not doubt. Among them are the natural beauties of the place, the restful life it affords, and its clear, bracing atmosphere. A gentleman, himself an invalid, who had visited here long before the place had become so well known, assured me that east of Colorado, after many trials elsewhere, he had found no air so helpful to him as this. But Blue Mountain Lake is but the entrance to a grand series of lakes beyond it. A little steamer every morning at eight o'clock leaves the landing near the hotel for Raquette and Forked Lakes,—types of the wildest and most beautiful of Adirondack scenery. I resist the temptation to say much of the beauty of Eagle, Utowanah, and Raquette Lakes, as well as of that of the narrow rivers which serve as outlets to the lakes, whose shores are deeply wooded and even now have begun to put on their early autumn foliage, where,

> "Double, in air and water, showed
> The tinted maples along the bank."

On Raquette Lake are many pretty private camps, as they are called, but which really are well-built cottages. Besides these there are several small public houses where many invalids have been spending the summer, and which, though not "splendid," are thoroughly "woods-like."

As I write from no other motive than the desire to be helpful to the sick, I must speak of these places as they impressed me when visiting them. At Kenwill's I found several very sick men, one of them a physician from New York, who had greatly improved since he came there, and who, although the subject of serious pulmonary disease, was determined and seemed to be likely to get well. But I was not favorably impressed either with the appearance of the bedrooms or with the table at Kenwill's, though those boarding there seemed to be satisfied with it.

At the northern end of Raquette Lake is a short "carry" which leads to Forked Lake, where the Forked Lake House daily furnishes dinner to the passengers of the little steamer, and where there are several other guests. The landlord is a kind and obliging man, and there is much to tempt one to stay here; but here, again, the table fails to furnish such food as an invalid requires, and until an improvement in this respect be made I cannot conscientiously advise the sick to stay there, notwithstanding the many attractions of the

* It is intended, next year, to shorten the stage-journey, so that the drive after night shall be entirely avoided.

neighborhood. On Raquette Lake, much nearer to Blue Mountain, is "Bennett's," a small and pretty rustic house which impressed me most favorably. It is situated close to the lake, has a forest in the rear, and furnishes most of the advantages, hunting excepted, which can be had in camp. The whole effect of the house was bright and inspiriting; even a mild cultivation of the æsthetic was noticeable, and the dinner which I partook of there was a good one. I know no house in this vicinity which seemed to me to furnish so much of the real woods-life as this did, and the bright, cultivated people who were here, several of them invalids, appeared to be getting its full benefit.

I have written of the life in the public houses, larger and smaller, in this region, rather than of that which is to be had in the camp itself, and I have done so because others have fully written on this latter subject, and because, too, I well know that, of the great numbers of the sick who go to the Adirondacks, comparatively few can or should go into camp. I say this last, too, with a full appreciation of the advantages which the real woods-life has for a certain class of the sick, as well as with an intense love myself for this healthful, restful,—I had almost said, this glorious,—life in the woods, of which Dudley Warner has so truly said, "he who has once experienced the fascinations of the woods-life never escapes its enticements; in his memory of it nothing remains but the charm." But, for the invalid, there is so much involved in the act of "going into camp," that he may well pause before he undertakes it, and inquire if it be possible to obtain even the approximate advantages without incurring the expense, the fatigue, and the privations which it entails. Especially is this the case where the invalid is a woman. I very much doubt if a woman is ever quite in her right place in a camp, while I am very sure that a camp, for a woman who is ill, is an *error loci*. I mean, now, real camp-life, not the elegant substitute which is to be found for it in the pretty cottages which dot the shores of Raquette and Long Lakes. In these the invalid, man or woman, may be as comfortable as at a hotel or at home, and here the presence of woman is often its greatest charm.

At such a house as Bennett's, where one almost necessarily lives out of doors in the daytime, but has three good meals daily and a good bed to sleep on at night, the approximation to the advantages of camp-life is a very close one. And so, too, with the inmates of the larger houses, by the use of a day camp, put up on the pretty shores of Blue Mountain Lake or on that of St. Regis, to which the invalid may perhaps walk, or, every morning, in his little boat, be pulled by his guide, almost the same woods-life and its advantages may be obtained. But it will not be worth while for either the tourist or the invalid to go so far from home if he pass the day or the greater part of it in the hotel, or, still worse, in his room.

I have very hastily written these pages in the few days which have elapsed since my return home, and I have done so in the hope that they may be directly of use to the sick, or, through the columns of this journal, may be of value to those medical men who wish to send patients to the Adirondacks, but who have not a personal knowledge of the places I have named.

For a month to come the beauty of this region will be very great. Already, as has been said, the foliage has begun to put on its autumn tints, and a more exquisite picture than the shores of Blue Mountain, Eagle, and Raquette Lakes in this party-colored dress it would be difficult to imagine. The Prospect House, I am told, will be open all winter, and the St. Regis House will receive guests for one or two months yet to come. The wonderful exemption which this climate affords the subjects of the so-called hay-fever—that strange expression of a gouty diathesis, as I have long believed it to be—will keep many pleasant people here for some weeks longer; for what Sydenham has said of the ordinary form of gout is true of this,—it has for its subjects

> "More rich men than poor men,
> More wise men than fools."

In conclusion, the writer wishes to say that there are doubtless other places in the Adirondacks where an invalid may be comfortable besides those he has named. He has written only of those which he has known by personal observation. Excepting only his old friend and host of St. Regis, he has but a casual acquaintance with the proprietors of the houses he has named, and he has written without fear and without favor. If by these hastily-written pages he can add to the comfort and diminish the anxiety of a single sick man who has been told to "go to the Adirondacks," he will be content.

JAMES J. LEVICK.

1200 ARCH STREET, September 3, 1881.

TREATMENT OF COMPOUND FRACTURES AND WOUNDS OF JOINTS BY GLYCERIN AND CARBOLIC ACID.—Mr. F. C. G. Griffin reports in the *Lancet*, June, 1881, p. 985, a series of cases, both of compound fracture and of opened joints, in which very satisfactory results followed the use of pads of lint soaked in the glycerinum acidi carbolici of the British Pharmacopœia, without the use of antiseptic spray or any other elaborate preparation. Mr. Griffin regards it as of much importance not to disturb the layers of lint immediately covering and generally adherent to the wound, until the latter has quite healed.—*London Medical Record.*

PROCEEDINGS OF SOCIETIES.

AMERICAN DERMATOLOGICAL ASSOCIATION.

FIFTH ANNUAL MEETING.

Held at NEWPORT, Rhode Island, August 30 and 31 and September 1.

FIRST DAY—EVENING SESSION.

(Continued from page 793.)

THE session being opened for the reception of communications, Dr. Arthur Van Harlingen, of Philadelphia, read a paper entitled

A CASE OF LYMPHANGIOMA TUBEROSUM CUTIS MULTIPLEX,

giving an account of a woman, 30 years of age, who displayed a large number of tumors of various sizes and shapes distributed here and there over the whole body, together with numerous teleangiectases and irregular brownish patches of pigmented skin. The tumors in some cases resembled flabby molluscum fibrosum growths, while in other cases they were smooth lilac or bluish elevations from pin-head to hazel-nut size, and so compressible under the finger as to feel like bladders filled with air and to give the sensation of an umbilical hernia in a child. On excision they were found to consist of a pearly gelatin-like semi-transparent mass, with a smooth, bulging surface and without fluid contents. Microscopic examination showed the structure to be composed of fibrous and granulation-cell tissue, with numerous irregular spaces, sections of dilated lymphatic vessels. But two other cases are on record,—one described by Kaposi in Hebra's work on Skin Diseases, the other reported by Pospelow in the *Vierteljahresschrift für Dermatologie und Syphilis.*

Dr. Louis A. Duhring, of Philadelphia, read a paper entitled

THE SMALL PUSTULAR SCROFULODERM,

describing a series of cases of a peculiar papulo-pustular disease of the skin, occurring chiefly on the arms and legs, though found on the face and elsewhere, and characterized by the formation of small reddish lesions, prone to recur and leaving a sharply punched-out scar. The affection resembles most closely the papulo-squamous syphiloderm, from which, however, the history of its course differentiates it. It also resembles the *acne cachecticorum* of Hebra.

SECOND DAY—MORNING SESSION.

The Committee on Statistics handed in its yearly report, including the classified statistics of some eleven thousand cases reported during the previous year. Appended to the statistical report was a report on leprosy in North America, based upon data contributed by the various members of the Association throughout the United States and Canada. These go to show that the disease is more prevalent in North America than has been generally believed. The rest of the morning session was devoted to the reading of papers on leprosy. Dr. Isaac E. Atkinson, of Baltimore, read a paper on

A CASE OF TUBERCULAR LEPROSY,

giving an account of a native of Maryland, a person who had never lived out of the State, but who acquired the disease while resident there. The only possible source of infection to which the origin of the disease could be traced was in the person of a leper living in the neighborhood,—a case already reported by a member of the Association. This leper was on familiar but not intimate terms with the family of the patient. No direct contact of any kind could be ascertained.

Dr. James Nevins Hyde, of Chicago, then read a paper entitled

STUDY OF A CASE OF ACUTE TUBERCULAR LEPROSY,

giving full notes of an extraordinary case coming under his observation during its whole course, where the disease developed with great rapidity and led to a fatal result. Dr. Hyde also read a paper communicated to the Association by Dr. H. D. Schmidt, of New Orleans, entitled

PATHOLOGY OF LEPROSY.

A paper by Dr. William Fletcher, announced to be read by Dr. Duhring, and entitled

CASES OF LEPROSY IN CAPE BRETON, NOVA SCOTIA,

was in order, but, owing to mischance, was not received in time.

SECOND DAY—EVENING SESSION.

The discussion on leprosy was continued.

Dr. James C. White said he was becoming more and more convinced of late of the contagiousness of leprosy through inoculation. The rise and spread of the disease in the Sandwich Islands seems convincing as to its contagiousness. He would ask Dr. Atkinson if he could explain how contagion took place in this case.

Dr. Atkinson could not say. There were open sores on the old case. Of course he could not assert that there had been no sexual intercourse, but the social standing and respectability of Dr. Atkinson's case was strongly against the possibility of such an occurrence.

Dr. White continued with regard to Dr. Hyde's case. He was inclined to question the diagnosis, as the history seemed a very unusual one and the portrait of the case shown by Dr. Hyde did not resemble tubercular leprosy as ordinarily met with. He would be more ready to accept the diagnosis after a

careful microscopic examination of the lesions had been made.

Dr. J. E. Graham, of Toronto, said that Dr. Keys, who had examined the lepers at Cape Breton, thought the disease contagious only by inoculation. Drs. Bayard and Wilson were of the opinion that it was contagious in a more general sense.

Further discussion turned chiefly upon the pathology of leprosy, some of the speakers inclining to the view, at present becoming prevalent, of the presence of a bacillus, while others, as Dr. Heitzmann, suggested a probable origin in the central nervous system.

Dr. Hyde, in replying to criticisms upon his paper, said he himself was not absolutely positive as to the diagnosis of his case. He would not come to a conclusion until a careful histological examination of the lesions had been made.

Dr. Edward Wigglesworth, of Boston, read a paper on

BUCCAL ULCERATIONS OF CONSTITUTIONAL ORIGIN.

These are usually syphilitic in nature, though they are not always so. The fact that syphilitic ulcerations sometimes occur in persons above all suspicion of sexual immorality makes it doubly important for the general practitioner to recognize them by their appearance without asking too many questions. The only maladies likely to occasion doubt in regard to diagnosis are lupus and tuberculosis, and occasionally epithelioma. In cases of lupus the local treatment is identical with that adapted to ulcerations due to syphilis. When tuberculosis exists with ulcerations of the fauces or palate, or both, the pulmonary symptoms are almost always far advanced, and even when they cannot be detected the patient is sure to die of tuberculosis, more or less general, and treatment is practically useless. The possibility, however, that the case may be one of either of these diseases should always make the practitioner careful in expressing an opinion and considerate in his language, for the peace of a whole family is often at stake.

The writer then went on to give notes of a series of illustrative cases, and followed these by some general remarks on the treatment, particularly of syphilitic ulcerations. Stimulants are better than caustics, and, indeed, much harm is done by the indiscriminate use of the latter. The parts must be kept well cleansed, and this alone, when the ulceration is in the pharynx, gives great relief. The writer recommended the following solution for atomization:

℞ Tinct. iodini, pts. v;
Glycerinæ, pts. x;
Aquæ, pts. xxx.—M.

The most convenient instrument to use is that known as Fulgraffe's, which is made of hard rubber, with nozzles of various shapes,—one to send a stream of spray up behind the soft palate, one for a horizontal stream, and one for use in the larynx. The bottle should be kept nearly full, so that the stream may not be kept up longer than is intended, owing to compressed air remaining in the bottle. Three or four applications of twenty seconds each will be sufficient to thoroughly cleanse and stimulate any ordinary ulceration.

After the use of the spray, iodoform should be applied to the ulcer with a camel's-hair pencil, or blown on to it by an insufflator. A little powdered gum arabic mixed with the iodoform causes it to adhere better. Iodoform can also be conveniently deposited on the nasal mucous membrane by letting the patient inhale a saturated solution of the drug in ether.

Some cases require the use of the nasal douche with disinfectants. A convenient formula is one teaspoonful of chlorate of potassium with one-third as much carbonate of sodium and fifteen drops of a five-per-cent. solution of permanganate of potassium, all in a quart of water at 25° C., used with a fountain syringe. It is well to remember that a spray or a powder carried by a current of air may be used by blowing it into one nostril while the patient breathes through the open mouth. The spray then passes through the vault of the pharynx and escapes by the other nostril. If desirable, by instructing the patient to breathe through the nose, a powder may be blown into the larynx through the nostril.

Constitutional treatment is of course necessary. The lesions occurring late in the disease,—from the second to the twentieth year, and usually in cachectic subjects,—iodine must play a more important part than mercury. Cod-liver oil, ferric iodide, potassic iodide, iodine spray, and iodoform,—these are the great remedies. Of course all hygienic measures must be united with these.

THIRD DAY.

Dr. Charles Heitzmann, of New York, read a paper entitled

CLINICAL EXPERIENCE IN THE USE OF THE SOLUTION OF OXYSULPHURET OF CALCIUM.

This solution, commonly called after the name of Dr. Vleminx, who first introduced its use, has long been known in dermatology. It has been used chiefly for the treatment of scabies, and by Hebra for the removal of patches of psoriasis.

The solution of oxysulphuret of calcium is prepared as follows: Take one part of quicklime, two parts of precipitated sulphur, and twenty parts of water; boil in a china or glass vessel to the remnant of twelve parts, and filter. The dark-brown liquid resultant has a disagreeable smell and is a strong caustic. Oil of anise will in part obviate the objection-

able smell. The solution may be diluted with water or alcohol, the latter precipitating the sulphur, but not materially altering its composition.

The writer had used it in thirty cases of psoriasis of the body, the solution being applied in full strength or diluted, according to the susceptibility of the patient's skin, being rubbed into the patches with a piece of flannel until slight stinging ensues. Care must be taken not to irritate the skin by a too strong solution. Tar ointment is afterwards to be rubbed into the patches.

The writer had employed the solution of oxysulphuret of calcium in ninety-five cases of acne disseminata, of which seventy-five were cured; in twelve the result was unknown, and in three cases the disease was aggravated. The solution is in these cases to be diluted with three to six parts of water, rubbed into the face with a flannel rag, and left on over night. The next morning the face is washed with soap and water. The solution may be employed of greater strength as the patient becomes accustomed to it. Cold cream may be used to disguise the slight desquamation.

The writer had also employed the solution in a few cases of chronic eczema,—fourteen in all. In four cases of chronic eczema of the scrotum, the application of dilute Vleminx's solution, gradually strengthened, resulted in a cure.

Thirty-six cases of rosacea were treated by the writer, with good result in twenty-nine cases.

A limited number of cases of tinea tonsurans were treated by means of the solution, but without beneficial result. Eleven cases of tinea versicolor were treated, with brilliant success in every instance, the solution being used in half strength. It appears to be the safest and surest remedy in this affection.

Finally, six cases of scabies were treated, all successfully.

Dr. Heitzmann also read a paper entitled

REMARKS ON AKIDO-GALVANO-CAUTERY (ELECTROLYSIS) FOR EPILATION,

giving an account of his personal experience with this admirable method, which was introduced a few years ago by Dr. W. A. Hardaway, of St. Louis, a member of the Association.

The report of the committee on examination of a specimen of Ainhum presented last year by Dr. Da Silva Lima, of Bahia, was then read. The committee was of opinion that the disease is the result of artificial constriction of the toe by the negroes who present this deformity.

The various microscopic specimens illustrating the various papers read at the meeting were then placed under several microscopes and demonstrated to the members of the Association. After considerable discussion on these, the Association adjourned, to meet in Newport on September 1, 1882.

The following gentlemen were elected to serve as officers during the coming year: President, James Nevins Hyde, of Chicago; Vice-Presidents, W. A. Hardaway, of St. Louis, and George H. Fox, of New York; Secretary, Arthur Van Harlingen, of Philadelphia; Treasurer, Isaac E. Atkinson, of Baltimore.

PHILADELPHIA ACADEMY OF SURGERY.

STATED MEETING OF JUNE 6, 1881.

DR. R. J. LEVIS, Vice-President, in the Chair.

ETHYLATE OF SODIUM AS A CAUSTIC.

DR. R. J. LEVIS presented a specimen of this agent, and said, "I have used the ethylate of sodium for some special purposes as a caustic since my attention was directed to it by the several articles of Dr. B. W. Richardson, of London, and am convinced that it possesses peculiar and decided merits. It seems to be applicable to the destruction of morbid tissues which are not amenable to operative treatment by excision or strangulation. Its special merits seem to be that it is rapidly effective, controllable in action, and antiseptic. Its influences seem to prevent suppuration and putrefaction beneath the tissues sphacelated by its action. Its controllable character is certainly one of its marked advantages, as it is not inclined to spread by increased liquefaction on the surrounding parts.

"The ethylate of potassium may also be used, and it is a more powerful caustic than the ethylate of sodium; but Dr. Richardson prefers the latter. The ethylate of potassium is violent in action, and hemorrhage has followed its application.

"In making the ethylate of sodium, Dr. Richardson directs that half a fluidounce of rectified alcohol (sp. gr. 0.975) be put into a two-ounce test-tube, set up in a bath of cold water, to which are to be added, in small pieces at a time, some cuttings of pure metallic sodium. Hydrogen will at once escape. Then add sodium until the gas ceases to escape, warm the water in the bath to 100° F., and add a little more sodium until the gas again ceases to escape; then cool down to 50° F., and add half a fluidounce more of alcohol. This will give a solution of proper strength for general use as a caustic. But it can be made more active, if desired, by the addition of more sodium. The caustic should be kept in a glass-stoppered bottle, in a cool place, and not exposed to direct sunlight. Bottles made with a pointed stopper, which dips down into the solution, are convenient for its application. It may be used over extensive surfaces with the brush of glass fibre, or as well by the ordinary camel's-hair brush; but the brush is destroyed by a single use of the caustic. A

glass rod dipped into the bottle will do for its usual application. The ethylate of sodium must not be diluted by other fluid than alcohol.

"Dr. Richardson says that his use of the ethylates was founded on what is evident of their physical action. It seemed reasonable that if the ethylate were applied to a moist external growth there would be produced two changes,—a caustic action would be set up, and, at the same time, the alcohol would cause instant coagulation of the fluids of the part, so that the destruction would be *purely local and concentrated*. In addition to this there would be the advantage of the antiseptic action, which is so marked.

"The alcoholic solution of ethylate of sodium used by me was made by Wyeth & Brother, of this city. Pure ethylate of sodium, as a dry crystalline salt, is made by Dr. L. Wolff, chemist; but I have not yet had an opportunity of using it.

"Ethylate of sodium has been used subcutaneously, injecting twenty or thirty drops into malignant structures.

"The dry crust on surfaces to which the caustic has been applied should be removed before another application is made, but no force should be used in the detachment. The pain which follows the caustic action, if too long continued, may be relieved by applying undiluted carbolic acid to the part. For this purpose the crystals of carbolic acid are to be liquefied by heat and the solution applied with a brush."

EXCISION OF THE REDUNDANT SCROTUM FOR THE RELIEF AND CURE OF VARICOCELE.

Dr. M. H. Henry, of New York, was introduced, and made the following remarks on his method of treating varicocele by excision of the scrotum:

My own personal experience leads me to think that varicocele is not a common affection. This view is, I am aware, in conflict with the opinions of many distinguished surgeons. As chief surgeon of the Police Department of New York, I have for many years examined with my assistants applicants for appointment on the force. The result shows the following. During the years 1876–80—five years—1978 applicants submitted to thorough examination, and of this number 41 were rejected for varicocele and 61 for varicose veins of the lower extremities; 7 of the 41 cases of varicocele had also varicose veins of the legs. No one was examined who was not of age, nor, so far as it was possible to ascertain, who was beyond thirty years of age. These restrictions limit the examinations to the age in which, according to all standard authors, varicocele is most likely to occur and be developed to its greatest extent.

This will, to many, seem a small percentage of cases for the large number examined, and it might, without reflection, lead to the belief that the examinations were not very rigid. They are; but it is accounted for in the fact that the applicants are mostly men of the lower working-classes, of robust health, and of more than ordinarily good physique. It affords evidence that varicocele is an affection confined, to a great extent, to persons of feeble or impaired constitution or delicate habit of body, excepting those cases where it suddenly follows an injury or severe strain. This view is sustained by the experts in venereal diseases. The percentage is at least one in ten of those suffering from this class of affections, especially of those suffering from syphilis and old cases of stricture and gonorrhœa. During my term of service as surgeon-in-chief of the State Emigrant Hospitals, covering a period of more than seven years, cases of varicocele were rare, notwithstanding the service was very large. From January, 1873, to January, 1880, in my division, 10,227 patients were treated. This number included cases covering the whole range of surgery and surgical diseases. I am unable to give any reliable statistics. The records were so imperfect, and the assistance afforded me so inadequate, that it was impossible to utilize for reference this interesting field of observation. I believe, however, that the only cases of varicocele called to my attention were in the venereal wards and coexistent with some other disease.

Before referring to the features of varicocele and the operation I advocate for its relief, let me remind you that the main changes that take place in the veins are: 1st, the elongation of the vein; 2d, its tortuosity; 3d, the loss of the function of its valvular apparatus; and, 4th, the loss of resiliency of the veins, which is of various degrees of intensity. This loss of resiliency is due to certain structural changes which take place in the walls of the vein, consisting of a thickening of their coats by proliferation of their connective-tissue elements, following which there occurs fatty degeneration of the muscular elements, which, later on, may increase to a complete calcific degeneration.

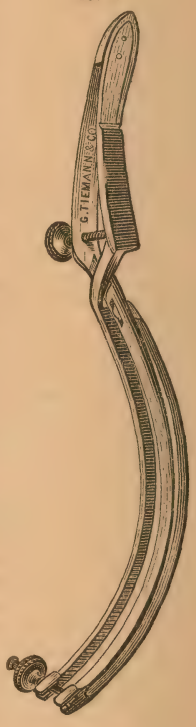
In taking these changes into consideration, it will readily be seen that the various cases met with present phases varying in proportion to the extent of the progress of the pathological changes,—namely, those in which there is very little loss of resiliency, in which the varicocele would be slight, and those in which there is an absolute and entire loss, in which case the varicocele would be exceedingly large. As a result of this varicose condition of the veins, greater or less atrophic changes may take place in the testicle. These changes which take place in the veins react on the scrotum, which gradually becomes enfeebled, lengthened, sometimes thinned and redundant. This redundancy, which is probably due to an atony of its dartos muscle, may consist of walls of scrotal tissue of normal thickness, but, from clinical observation, I

think I am warranted in stating that there is thinning of the scrotal walls in the majority of cases: the intensity of this condition is in direct relation to the extent of the varicosity. It may be well to mention here that in many cases, particularly where this thinning of the scrotal walls exists, there is decided enlargement of the superficial scrotal veins.

I will not detain you by making any remarks on the many views, suggestions, and operations for the relief of this disease. I can only say that I believe amputation of the scrotum to be the best and safest of all surgical procedures. I am somewhat surprised that it is not in favor in England, nor has it received much attention from the Continental surgeons. Strange as it may seem, while Mr. Curling ignores the operation, he cites an admirable illustration of its value in the last edition of his work on the diseases of the testis. In a case related to Mr. Curling by Mr. Coulson, "the patient compressed the ring so tightly as to cause a slough of the integuments, which, having separated, was followed, fortunately, by such contraction of the part as to raise the testicle and afford relief from the uneasy symptoms of the complaint." I have met with a similar result following a case of sloughing due to a phlegmonous erysipelas.

Mr. Henry Lee, of London, recently advocated the removal of a portion of the anterior skin of the scrotum and subsequently dividing the veins which are to be obliterated. All the steps of the operation are conducted through the wound made by the removal of the skin. The veins are temporarily compressed to prevent hemorrhage, and then divided. Mr. Lee said that his object in interfering with the scrotum was to prevent any return of the varicocele. If Mr. Lee's operation is to effect a radical cure—which he claims—of the varicocele by obliterating the veins, and the removal of the redundant scrotum is of no service, I fail to see how his interference with the scrotum, such as he describes, will prevent any return of the varicocele. I allude to these suggestions because they emanate from a distinguished surgeon, who seems to have ignored the results of those who have advocated the removal of the scrotum for the relief of enlarged spermatic veins.

The only objector to this operation, as far as I can learn, is Dr. Frank H. Hamilton. His objection is based on *one* failure to cure on the part of a young man who did the operation shortly after I published my first paper,—ten years ago. The young man held a public appointment, and was subsequently dismissed for incompetency and deficiency of professional knowledge. He was Dr. Hamilton's pupil.



In the removal of a redundant scrotum in the manner I describe, for the relief of varicocele, no more than ordinary skill is called for. The success of any delicate surgical operation depends mainly on the care and management before and after the operation. I venture to allude to many little details because I am fully impressed that they bear an important relation to the chances of success.

Success in any operation depends on attention to details. Cases of minor surgery have frequently, by neglect of details, been converted into cases of major importance.

DESCRIPTION OF INSTRUMENTS.

The instrument which I have called scrotal forceps, or clamps, consists of two parts (Fig. 1). The main part of the instrument has two double-curved blades, made of steel, about ten inches long, sufficiently heavy to give strength and admit of pressure without injury when in contact with the tissues. The handles are large enough to admit of a good grasp without cramping. That part of the instrument below the joint is curved as nearly as possible according to the natural lines of the raphé, from the upper anterior part of the scrotum down to and under the scrotum, so that it embraces, when placed in front of the scrotum, the entire and exact portion which it is desired to remove. The coapting surfaces are evenly notched to prevent the tissues from slipping, affording a more secure hold on the soft parts, with less pressure and less injury than smooth surfaces. The blades are only thick enough to give strength without leaving too much tissue in front. The handles are curved so that, while they maintain a direct median line, they do not interfere or press on the genital parts. The double spring, besides giving additional security and compactness, renders them, to a great extent, self-acting.

Fig. 1.

The screws in the handle and at the end of the blades afford a complete and perfect hold of the parts to be removed. They are not adjusted until the operator is perfectly satisfied that he has embraced the exact portion to be removed in front of the blades.

The extra blade is made of steel, nickel-plated, and is maintained in the right anterior surface of the clamp by two small pins that fit in grooves cut in the clamp. It is easily inserted with a little pressure, and removed as easily by pressing downward and forward; it is then dislodged by slightly raising the extreme end. The extra blade, when in position, leaves a fenestra to afford the surgeon

the facility of inserting all his ligatures, should he prefer it, before dividing the parts. The thickness or amount of the tissue left in front of the main blade and between that and the extra blade, which is the guide for the part to be removed, is ample to assist union; and if the division is a clean one, and the stitches are close and evenly inserted, the pressure and tension is so slight, or, rather, divided over the entire cut surfaces, that there is little probability of ulceration through the stitches before union has taken place. The stitches must be so nicely taken that the edges are approximated without being too tightly drawn together. If the tissues at the points of insertion of the stitches are too tightly compressed, the cut edges may bulge out. This can be avoided with a little care such as I suggest.

When the part has been removed the extra blade is displaced, leaving a free border exposed in front of the main blade about a quarter of an inch in thickness. In a few minutes the whole wound can be stitched without any inconvenience. The clamp is, of course, not removed until this is accomplished.

Besides the clamp, the only instruments necessary are the scissors or scalpel, needles, with either silk or fine silver wire for sutures, a few acupressure needles, a few *serres-fines*, silver pins, and some adhesive plaster.

For the removal of the redundant portion I prefer scissors to the knife. I am inclined to think the hemorrhage is apt to be less and the cut edges heal more readily by first intention. I cannot give any positive explanation for this, but such is my impression. When the double layers of the scrotum are tightly compressed between the blades of the clamp, it forms a very dense, tough substance, and requires a pair of very strong, sharp scissors to cut through. It is as dense as cartilage. A strong pair of scissors will, with some extra effort, serve the purpose; but, to insure an easy and clean removal of the part, I use a cutting instrument which I have named cartilage-scissors (Fig. 2). I have dispensed with the rings. These scissors can be grasped and handled with the utmost ease. By the aid of the springs on the inner sides of the handles they are self-acting so far as opening the blades. They are curved on the flat side. They are not only useful for this operation, but will, I think, be found to serve better, and are handled with greater facility, than any other scissors, wherever a cutting instrument is needed for cartilage or other dense or thickened tissues.

Fig. 2.

The instruments were made by Messrs. Tiemann & Co., of New York. I need scarcely say that they are as perfect as it is possible for any instrument-maker to make them. Before any anæsthetic is administered, the patient should be carefully examined, and the forceps applied while in a standing position: this will afford the surgeon the best opportunity to decide the exact portion of scrotum to be removed. If this precaution be taken there is no danger whatever of his removing too much tissue. I am satisfied there is much more danger of his not cutting off enough. The patient being placed in a recumbent position, his thighs well separated with folded towels, the forceps are applied by placing the blades in front and under the anterior portion of the scrotum, and held in a direct median line. The end of the forceps being close to the perineum, the scrotum is then engaged between the blades of the forceps. Care must, of course, be exercised not to include anything more than the scrotum. As soon as they are adjusted and the proper amount of tissue to be removed engaged between the blades, the screws should be tightened and the part removed.

I find that by carrying the incision very low down, to the lowest and most pendulous part of the scrotum, it affords the easiest egress for any little portion of blood or serum that might collect there, and at the same time prevents, or at least lessens the chances of, an abscess. While I have never met with any such complication, I am nevertheless aware of the possibility of such an occurrence.

I use the ordinary interrupted suture; it affords advantages over the running stitch should it subsequently be found necessary to divide one or two stitches in case of hemorrhage or in case of severe œdema. If the interrupted suture be used, each stitch, being independent of its neighbor, affords facilities under these circumstances which I think are of no small value. The stitches should be close together. I have used silver pins and the figure-of-8 ligature—the same as practised in cases of hare-lip—in three of my operations. They all did well.

Teats, or angular points, are sometimes left at each end of the wound. This may be avoided by a slight rounding of the corners. Should any vessel be divided requiring special attention, the application of a small acupressure needle will be found most serviceable. If the bleeding occurs on or very near the border of the incised parts, I apply a *serre-fine* or acupressure needle.

In persons of a feeble or debilitated constitution diffuse hemorrhage may occur, as in any surgical operation. This is best treated by the local application of ice or of a solution of the persulphate of iron. In persons of a true hemorrhagic diathesis the operation should not be performed.

It has been suggested that there was danger

of a retraction of the dartos muscle in amputation of the scrotum; this, I think, cannot possibly occur if the forceps are used with ordinary care.

The treatment following the operation is very simple. A few strips of india-rubber adhesive plaster are fastened around the testes to assist in maintaining the cut edges of the scrotum in perfect apposition and to prevent any dragging on the stitches; a broad strip of adhesive plaster is then placed under the most dependent part of the scrotum and fastened on either side of and above the pubis. The wound should be kept perfectly clean and sponged three or four times daily with a weak solution of carbolic acid and water. Should any untoward symptoms manifest themselves, they would, of course, be treated on general principles.

When the wound has entirely healed and the patient is able to go about, I have been in the habit of advising the use of a suspensory bandage for some time. This precautionary measure is, I think, of decided benefit, allowing, or rather assisting, the enlarged veins to recover from their morbid size and condition.

The main objection urged against this treatment by persons who have never witnessed any of the good results of the operation is the fear of erysipelas. I have never seen any complication of the kind follow the operation, nor do I believe that there is any greater tendency to excite any phlegmonous inflammation in this operation than there is in any other surgical procedure in other parts of the body. The adoption of Lister's apparatus and method of after-treatment would doubtless lessen the risk in the estimation of those who resort to it in their operations.

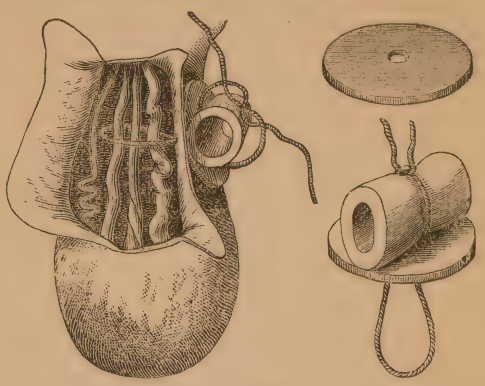
I was first led to perform this operation because it was suggested by Sir Astley Cooper, who published five cases which he regarded as successful in their results, and an additional case with some extraordinary features submitted by Mr. Key, who was also in favor of this operation, and preferred it to that of ligation of the veins. The difficulty in the performance arose from the want of a proper clamp. The one I presented ten years ago has met, I am pleased to state, with universal approbation. I have now performed the operation fifteen times during the past ten years without any unpleasant results. My cases have ranged between the ages of nineteen and forty-five. The varicoceles were all on the left side, excepting in one instance, when both sides were involved. Nine of the fifteen cases healed perfectly by first intention. The remaining six healed partially by first intention and subsequent granulation. Those that healed by first intention made perfect recoveries within a week. The longest period of confinement in any of my cases was fifteen days. This was the case of a young gentleman of feeble constitution, who had led an irregular course of life for some time before the operation. I operated in his case in February, 1878. The following year he called on Sir James Paget, and directed his attention to the results of the operation. That distinguished surgeon assured him it was a success. I had an opportunity of examining this patient about four months ago. The result was all that could be desired. In another case, operated on in May, 1872, I examined the patient in January last, and the result was equally satisfactory.

In June, 1870, I assisted a surgeon of this city, who removed the redundant scrotum for varicocele from a lad fifteen years of age. The want of a proper clamp rendered the operation a tedious and unpleasant one: there was no union by first intention, and for some time the case looked very unsatisfactory. April 7 of this year, I examined him and found the result to be a good one. He was perfectly satisfied.

In 1863, a gentleman, twenty-seven years of age, consulted a surgeon of this city for relief from a varicocele of left side. The veins were ligated by Ricord's method. The pains continued with the same severity, with the addition of more intense irritation and swelling along the course of the spermatic veins and in the inguinal region. This proved such a serious annoyance that, in 1864, he submitted to amputation of the redundant scrotum. I was present at the operation. The surgeon removed a large section entirely from the bottom and most dependent part, forcing the testes up high, so that when the patient assumed the erect posture the testes bulged out in front of the penis and became an additional annoyance. A third operation was performed,—the removal of a section from the anterior surface of the scrotum, along the median line. He was relieved of his suffering, with the exception of the irritation and swelling in the course of the spermatic veins in the inguinal region. In 1870, another surgeon pronounced that he had a hernia. Under his advice he wore a truss for one year. In 1871, another distinguished surgeon assured him he had no hernia, and confirmed his own impressions that his suffering was due solely to the ligation of the spermatic veins. He continues the use, more or less, of a suspensory bandage. April 14 of this year, I had an opportunity of examining him. The scrotum presented a normal appearance, and the spermatic veins were no longer any source of annoyance. He stated that he felt perfectly well, and said that if asked which operation he thought most advisable, he assured me the removal of the redundant scrotum would be his choice. He said that he would, under all circumstances, condemn ligation of the veins.

I give the details of this case because they furnish evidence of a practical character, after a lapse of sixteen years from the time the first operation was performed, and, ad-

ditionally, because they are given by an educated gentleman of much more than ordinary intelligence.



My experience has led me to the following conclusions: 1. Varicocele is a disease that may occur at any period from boyhood to middle life. 2. It occurs mainly in early manhood. 3. It is not of such frequent occurrence as generally believed. 4. It is mostly met with in persons of delicate or impaired constitutions, or in those who have become enfeebled by disease or venereal excesses, or both. 5. In robust persons it may follow a severe strain or direct injury in the region of and along the course of the spermatic veins. 6. It is sometimes complicated with disease of the testicle, hydrocele, and hernia. 7. A correct diagnosis is easily made with ordinary care and attention. 8. Ligation of the veins is not without risk and danger to life, and does not offer any decided prospects of a radical cure. 9. Ligation of the veins does at times cause loss of virility and atrophy of the testicle. 10. The obliteration of the veins by the galvano-cautery has so far proved only a substitute for the ligation of the vessels. 11. Amputation of the redundant scrotum offers at least as good a prospect of cure, without any chance of injury to the glands and without risk to life. 12. Union by first intention becomes as nearly as possible a natural sequence. 13. Dangers from hemorrhage and inflammation are reduced to a minimum. 14. The operation with this instrument is easy of accomplishment.

Dr. Thomas G. Morton spoke of a case of enlargement or elephantiasis of the scrotum, in which he had removed a section of skin and ligated both spermatic arteries. The man was improved by the operation. He also referred to the points of similarity between Dr. Henry's varicocele clamp and an instrument that he himself had devised about eighteen years ago for cutting out a section of skin in cases of entropium.

Dr. Henry stated that Curling mentioned an instance in which varicocele was cured by sloughing of the scrotum. In such cases, and in cases treated by excision, as described, it did not seem probable that the integument would stretch again, as the extensibility had been lost.

Dr. J. M. Barton referred to a case of free hemorrhage that occurred after excision of the scrotum by Dr. S. D. Gross.

Dr. R. J. Levis said that fifteen or eighteen years ago, during his service in the Philadelphia Hospital, he had treated a case of varicocele by cutting off a portion of the scrotum with scissors, but he did not cut away enough of the redundant tissue. In another case he had thrust needles through and tied up with a ligature as much as could be grasped, and then excised. This case he thought resulted better than the other. The attempts were rather awkward, but were in the same direction as the operation described by Dr. Henry. He had employed animal ligatures for tying the varicose veins, but had abandoned their use because of failure, due, in his opinion, to too rapid absorption of the catgut. He now uses a string, which he passes through a metal plate and ties over a small piece of rubber tubing, as represented on the blackboard. The rubber tube acts as an elastic spring to keep up pressure. The ligature does not usually cut through in less than five or six days.

Dr. C. B. Nancrede called attention to the fact that the condition was not merely one of mechanical stretching, but of new growth or hypertrophy, just as hypertrophy occurred in old herniæ.

Dr. John H. Packard asked whether there was any danger of grasping a portion of the vaginal tunic in the clamp and thus cutting it away with the scissors. He himself employed two double ligatures of fine wire, looped through each other and fastened by twisting together over a pad of wood. They could then be tightened up as desired during the ten days which it usually required to effect division of the veins. His patients had not complained much of pain, but the procedure is sometimes tedious. The method resembled Ricord's manner of performing the operation, but the apparatus was simpler.

Dr. S. W. Gross had had Dr. Henry's instruments as first made in his possession, but had always employed ligation. He preferred the elastic ligature because of the pain given when the ordinary cord was repeatedly tightened. The elastic ligature came away in about sixteen days.

Dr. J. Ewing Mears had recently seen two cases of atrophy of the testicle following ligation done by other operators. He thought the procedure described was rational and one that might take the place of the ordinary method of ligature.

Dr. Thomas G. Morton had never seen trouble follow the ligature. He always ligated in two places with silver wire. The upper ligature was applied close to the inguinal ring, the other about one and one-half inches below. The wires were usually removed in

forty-eight hours, though occasionally one was left longer. The symptoms were less violent than in the ordinary manner of ligating, but obliteration of the veins occurred as was desired.

NEURALGIA OF UPPER JAW.

Dr. R. J. Levis exhibited the patient with neuralgia of the upper jaw whom he had mentioned at the last meeting as a case in which he had pared away the periosteum of the alveolar process. No good result followed the operation, for the pain persisted.

ARTIFICIAL ANUS AND PROLAPSE OF THE INTESTINE FOLLOWING SLOUGHING OF A SCROTAL HERNIA.

Dr. J. M. Barton exhibited a patient, aged 67, who had had a right scrotal hernia for thirty or more years. About one year ago, after what appears from his description to have been a condition of strangulation or impaction, sloughing occurred, and an opening was formed through which fæces have since escaped. Subsequently the mucous membrane of the bowels became protruded at each end of the loop of intestine, which had been opened by the gangrenous process. At the present time there are several inches of prolapsed colon visible at each of the two openings. From the lower orifice fæces are discharged, showing it to be the upper extremity of the intestine; from the upper opening no evacuations occur. Very infrequently whitish material is discharged from the anus. [This patient was subsequently subjected to operation by Dr. F. H. Gross.]

CASE OF ATROPHY OF LEGS — PATIENT ENABLED TO WALK BY ADAPTATION OF ARTIFICIAL LIMBS.

Dr. Morton exhibited photographs of a young man who had paralysis and atrophy of the legs, whom he had enabled to walk by flexing the legs upon the thighs and adapting artificial limbs to the stumps thus produced. The boy was able to walk with the aid of canes, which was all that could be expected, as the muscles of the thighs were also diminished in power.

JOHN B. ROBERTS,
Recorder.

ATROPIA IN VASELINE.—Dr. Klein, of Vienna, recommends, in place of the ordinary solutions of atropin, to use an ointment prepared as follows: Sulphate of atropia, ¾ gr.; vaseline, 160 gr. If the atropin salt be thoroughly triturated with the vaseline, it is unnecessary to use any solvent. The application of this ointment is much easier than the instillation of the solution. It is best applied by means of a camel's-hair brush to the inner surface of the lower eyelid pulled down.—*London Medical Record*, June 15, 1881.

REVIEWS AND BOOK NOTICES.

CLINICAL LECTURES ON THE DISEASES OF OLD AGE. By J. M. CHARCOT, M.D. Translated by LEIGH H. HUNT, B.Sc., M.D. With Additional Lectures by ALFRED L. LOOMIS, M.D. New York, William Wood & Co., 1881. (Wood's Medical Library.)

In this compound volume about two-thirds have been written by Prof. Charcot, and the remainder by Prof. Loomis. After an introductory chapter on Empirical and Scientific Medicine, and one on the General Characteristics of Senile Pathology, there follow chapters on gout and rheumatism to the number of seventeen,—a very large proportion of the work, considering the infrequency of gout in this country. An appendix on temperature closes Charcot's part of the work, and all the other subjects—pneumonia, bronchitis, asthma, atheroma, fatty heart, cerebral hemorrhage and softening, chronic gastric catarrh, constipation, and hypertrophy of the prostate gland—have been treated of by Prof. Loomis, and form the best part of the work, very decidedly, we should say.

THE PRACTICE OF MEDICINE AND SURGERY APPLIED TO THE DISEASES AND ACCIDENTS INCIDENT TO WOMEN. By W. H. BYFORD, A.M., M.D., Professor of Gynæcology in Rush Medical College, etc. Third Edition. Philadelphia, Lindsay & Blakiston, 1881.

Dr. Byford's work having been so long before the medical public, and that public having decidedly expressed its opinion as its value by buying two large editions, it seems scarcely necessary to do more than chronicle the issue of another edition, with the failings of its predecessors, but with added virtues.

The author says in his preface, "Surrounded as I have been by such a throng of active workers, the results of whose labors I have tried to assimilate, my former ideas have been greatly modified, and, I hope, also improved."

THE COMPEND OF ANATOMY. For Use in the Dissecting-Room and in Preparing for Examinations. By JOHN B. ROBERTS, A.M., M.D., Lecturer on Anatomy and on Operative Surgery in the Philadelphia School of Anatomy, etc. Second Edition, revised. Philadelphia, C. C. Roberts & Co., 1881.

The first edition of Dr. Roberts's little book has been exhausted within six months of its appearance,—a fact which speaks well for its popularity among students of medicine.

Though this fact, alone considered, would by no means indicate special worth in any given case, yet in the present instance we are inclined to think the medical student has done well to absorb such a useful and carefully-arranged anatomical guide. By adopting a condensed style, putting in no irrelevant mat-

ter, and saving space where space could be saved, the author has managed to crowd a vast amount of anatomical knowledge into a very small space, and his book is certainly the best of its kind with which we are acquainted.

LECTURES ON DISEASES OF BONES AND JOINTS. By C. MACNAMARA, F.R.C.S. Eng., Surgeon and Lecturer on Surgery at the Westminster Hospital, etc. Second Edition. London, J. & A. Churchill, 1881. 8vo, pp. 551.

Considerable change, in the way chiefly of enlargement, has been made in the second edition of Dr. Macnamara's book, and he has also altered the plan of the work so as to include lectures on diseases of the joints. In fact, as he states in his preface, the greater part of the work has been rewritten. The author's stand-point is that of the practical surgeon. He does not go deeply into the pathology of his subject, but in a series of chapters on the various affections involving the bones he gives a fair idea of the diseases of these structures as the physician and surgeon is apt to meet them. If he is unsatisfactory in any point, it is upon that of pathology. The practical part of the book is very good.

LECTURES ON THE SURGICAL DISORDERS OF THE URINARY ORGANS. Delivered at the Liverpool Royal Infirmary by REGINALD HARRISON, F.R.C.S., Surgeon to the Infirmary, etc. Second Edition, considerably enlarged. New York, William Wood & Co., 1881. 8vo, pp. 395.

When the first edition of Mr. Harrison's work appeared, it was reviewed in these columns at some length, and the judgment passed at that time may only be modified by commending the additions and enlargements to the subject-matter made in the present issue. We cannot so heartily commend the thick paper and loose, straggling-looking type, which, while bringing the volume up to a more considerable size, do so at the expense of making it more clumsy to handle than is necessary.

RHEUMATISM: ITS NATURE, ITS PATHOLOGY, AND ITS SUCCESSFUL TREATMENT. By T. J. MACLAGAN, M.D. London, Pickering & Co., 1881. 8vo, pp. 333.

Dr. Maclagan introduced salicin as a remedy for the treatment of rheumatism to the notice of the profession in 1876. In the present volume the miasmatic theory of rheumatism, referred to in the paper just mentioned, is more fully expounded, and an explanation is offered of the manner in which the salicyl compounds produce "the marked antirheumatic effects which they are now all but universally acknowledged to possess."

That portion of the book to which the reader will first turn is the chapter on the malarial origin of rheumatism. This Dr. Maclagan believes in, and he endeavors to prove his views by argument at considerable length. Considering the malarial origin of the disease proved, he then goes on to show why the salicyl compounds are useful. The book is one for the clinical investigator, and is not a text-book of practice.

LECTURES ON DIGESTION. An Introduction to the Clinical Study of Diseases of the Digestive Organs. Twelve Lectures delivered to Practitioners and Advanced Students of Medicine during the Winter Session, 1878–9, by DR. C. A. EWALD, Lecturer in the Royal University of Berlin, etc. Translated by ROBERT SAUNDBY, M.D. Edin., etc. New York, William Wood & Co., 1881. 12mo, pp. 150.

Dr. Ewald's lectures are already known to many members of the profession, and to these nothing need be said as to their value. The appearance of the present edition gives us the opportunity of recommending the work to the attention of practitioners who are desirous of obtaining in a small compass the results of modern research on the digestive functions. Though strictly scientific, Dr. Ewald's lectures are in the highest degree practical, dealing with the digestive function from the practitioner's stand-point, and not from that of the mere physiologist.

GLEANINGS FROM EXCHANGES.

URETHRAL FISTULA.—At a recent meeting of the Société de Chirurgie, M. Poncet related the case of a man who came to him with a lesion of the penis producing a urethral fistula. This individual, suffering from hypospadias, introduced into his urethra certain foreign bodies, among others a gold watch-chain, which caused considerable swelling of the prepuce and a fistula. M. Poncet was able to close the fistula by paring the edges and introducing deep and superficial sutures. This treatment succeeded admirably, but the patient on leaving the hospital deliberately tore open the cicatrix.

Hermaphrodism.—Another member reported a very curious case of hermaphrodism. A man, born of healthy parents, was registered in his district as belonging to the female sex. At the age of thirteen menstruation commenced, and at the same time the breasts were seen to develop themselves, and "she" was observed to have inclinations common to her sex at that period. She got married, but copulation was never able to take place. Her husband died in 1871. After that time her ideas changed; she had several mistresses, with whom coïtus was regularly accomplished. She shaved every second day; the face is not very masculine, yet the body in its outline approaches nearer that of the male sex. The penis is no larger than that of a child twelve years old. There

is hypospadias. In each labium can be felt a rudimentary testicle. There is no vagina or uterus. This hermaphrodite belongs to the class of the imperfect bi-sexual hermaphrodites of Geoffrey St.-Hilaire. M. Pozzi believed it was more the case of a man with hypospadias than a true hermaphrodite. The infundibulum between the labia was due to the attempts at copulation. The feminine voice and the voluminous breasts were not astonishing, as the same are observed in eunuchs. He believed that hermaphrodism is getting very rare. For the last twenty years not one true case was demonstrated. M. Pozzi was sustained in his views by all the other members, with the exception of M. Tilleux, who thought that hermaphrodites really existed.

Bromide of Potassium in Epilepsy.—In a classical book styled "Nouveaux Eléments de Matière Médicale et de Thérapeutique," the authors declare that in the treatment of epilepsy in adults drachm doses of bromide of potassium should be given daily, and gradually increased to two or three, or even six, drachms in the twenty-four hours. This opinion, constituting a grave error and fraught with danger, induced M. Ferraud, who has been a close observer of the results obtained at the Salpêtrière Hospital by M. Sequard de Saulle, to devote his *thèse* to the treatment of this disease as followed by this physician. In comparing the years 1879 and 1880, M. Ferraud divides the epileptics into three categories: the first comprises those patients who for some considerable time have had no more attacks; the second, those in whom the attacks have sensibly diminished by half or more; and the third, those who have been only slightly relieved. Of seventy-nine patients, twelve belong to the first group, fifty-one to the second, and sixteen to the last. M. de Saulle commences with thirty or forty grains, at the most, of bromide of potassium in the twenty-four hours, and after the first fortnight, according to the case, increases it by eight grains. At the end of the second fortnight another slight increase is made, so that at the end of from three to six months the daily dose of from sixty to ninety grains for women and eighty to one hundred and twenty grains for men is attained. These doses should, if possible, not be exceeded. Under any pretext the salt should not be increased too rapidly, for fear of inducing bromism. As soon as a patient remained one year without an attack the medicine was given every second day during the first fortnight of each month, and every day for the second. At the end of two years, if the patient still remained free from attack, the bromide was given but every fourth day during the first fortnight of each month, and every day during the second, and so on. M. de Saulle believes that the reason that medical men are so much discouraged in the treatment of this disease lies in the fact that as soon as a slight amelioration is observed the dose is diminished progressively. He has at present four epileptics who for more than twelve years have not had one attack, yet they have not entirely suspended treatment. Bromide of potassium has been accused of weakening the memory; but this effect is observed only where the daily dose exceeds three or four drachms. In any case, M. de Saulle, when he reaches the dose of ninety grains, orders two or three cups of strong coffee to be taken in the day as a preventive. He has thus never seen any evil results from the salt.—*Correspondence Medical Press and Circular.*

Treatment of Chorea.—At the end of a paper on chorea, based upon an experience of one hundred cases (*British Medical Journal*, vol. ii., 1881, p. 145), Dr. William Strange speaks of the treatment, saying that the changes must be rung on the so-called nervine tonics, varying them according to the temperament of the child or to the collateral symptoms accompanying the choreic movements. If pallor, palpitations, and loss of weight exist, iron or arsenic, or both, will be necessary. If, on the contrary, the vascular system be sufficiently full and the motile element prevail, then the bromides with ammonia, or the succus conii, will be of most avail. Frequently, whatever the condition of the vascular system and of the general nutrition, no good arrives until we have succeeded, by sedatives, in calming the excessive mobility of the nervous system. In these cases Dr. Strange has used the ice-bag to the spine and the ether spray to the nape of the neck, but not with much success. Direct calmatives—digitalis, belladonna, cannabis indica, with the bromides—answer the best.

The nervous symptoms once quieted, iron or arsenic may now be given, and carried to a somewhat high degree. Some have recommended large doses of arsenic, ten to fifteen minims of Fowler's solution; but Dr. Strange has seldom found that the stomach will tolerate these large doses, and has contented himself with much smaller ones, in combination with iron or zinc.

But, whatever the remedy selected, it will be necessary to continue its administration until it has produced its special physiological effect. Especially is this necessary with the neurotic sedatives. Children bear large doses of belladonna and conium; and Dr. Strange has never found this class of remedies do much good until their full physiological effects (consistent with safety) have been produced.

Dr. Strange used some years ago to treat all his cases of chorea with wine alone, the port wine of the hospital, merely clearing out the primæ viæ, to make sure that trouble was not caused by entozoa or depraved alvine secretions. The amount given was three to six ounces daily, and all the cases got well.

After suspending this treatment for some years, he has recently recommenced it with good results.

Abdominal Abscess as a Result of Enteric Fever.—Dr. R. Bruce Low (*British Medical Journal,* vol. ii., 1881, p. 122) says that abdominal abscess after enteric fever is not often met with. Little information regarding it is given in the text-books. For this reason he places on record two cases which he has met with in practice. The first was that of a girl of five, who had peritonitis in the third week of the fever. From this she rallied, and the distention of the abdomen gradually subsided, leaving only a hard and painful swelling on the right side of the umbilicus. Poultices were applied for a few days. After this the abscess burst spontaneously, discharging horribly offensive pus, and healed up at the end of ten days. The child recovered.

A second case, a girl of seven, had a typical attack of typhoid fever. During the fourth week pain was complained of in the umbilical region, and a hard lump gradually developed to the right of the navel. It could be seen projecting under the abdominal wall as large as a cricket-ball. Poultices were applied. Four days after, the doctor was informed that the lump had burst. The child had asked for the bedpan, into which she passed *per anum* about a cupful of pure pus. On examination, no trace of the lump in the umbilical region could be found. All the symptoms disappeared, and the child made a rapid recovery.

Dr. Low remarks that the origin of the abscess in the first case seemed to have been due to peritonitis arising probably from a deeply ulcerated Peyer's patch, with matting of the intestines, and possible subsequent perforation, with consequent encysting of the extravasated contents of the bowel, which ultimately were discharged through the abdominal wall in the form of an abscess. In the second case the abscess was probably due to the suppuration of a swollen and inflamed mesenteric gland, which had excited adhesion to the bowel, through which it opened and discharged its contents without any bad results. Both children were scrofulous. The occurrence of abscess is important in connection with the possibility of pyæmia after enteric fever.

Urethral Fever—The Use of Aconite and Morphine.—In a report of his hospital service (*New York Medical Record*) a case of urethral fever was alluded to by Dr. Weir. It was of that form which occurs when the urine passes over the cut surface for the first time, rarely before. In such instances the temperature may rise to 104°, 105°, or 106°, rapidly falling the next day. To prevent this rise, aconite and morphia are to be given in doses of three to five minims of the former to one-eighth of a grain of the latter. This is to be repeated after a lapse of two hours, and, if necessary, a half dose may be given at the end of two hours more. This is done because the fever is nervous and due to irritation communicated from the wound to the nervous plexuses supplying the kidney. Dr. Weir's experience with quinine in these cases has been rather negative.

The Fluorides in Medicine.—Dr. J. M. Da Costa (*Archives of Medicine*) has been making some experiments with the salts of fluorine. Fluoride of potassium, of sodium, and ferrous fluoride were the preparations chiefly tested. The fluoride of potassium was best borne and more used. This was given in doses of two or three grains. It was first given in a case of subacute rheumatism with considerable pain. The pain was considerably relieved without producing drowsiness. Gastric disturbance soon set in, however, and the drug had to be stopped. In other cases of rheumatism like effects were produced.

Reviewing the experiments, Dr. Da Costa says that the fluorides, especially the fluoride of potassium, in large doses are prompt emetics without depressing. They seem to relieve pain without producing sedation or sleep. They cannot be given long without producing gastric trouble. Their most singular effect, which is manifest especially with the iron salts, is the anorexia that is produced even by small doses. It is suggested that they may be of use in boulimia, or to counteract the craving for drink. On the whole, however, it seems unlikely that their therapeutic usefulness will be great.—*New York Medical Record.*

The Treatment of Ranula.—An important discussion took place before the Société de Chirurgie on the treatment of ranula, in which nearly all the members took part. M. Deleus recited a case in which the cyst was excised and cauterized, but at the end of two months it returned. This fact, he believed, resulted from the migration of the sublingual ranula through the muscular fibres of the floor of the mouth and developing a cyst in the buccal cavity. M. Trelat for many years excised with the scissors in the case of small ranulæ, and where they were more voluminous he treated them by puncture and the injection of iodine. M. Després treated every kind of ranula by the drainage, and always with success. M. Verneuil observed that he tried many methods in the treatment of ranula, but with varied success. He adopted the plan of slow section, for which purpose he passed a curved needle charged with a double thread of silver wire through the cyst, and united both ends in a firm knot. In five or six days the section was effected. M. Labbé did not doubt the success obtained by M. Després by his method, but he considered that to keep a seton in the mouth for six months to cure a ranula constituted a verita-

ble infirmity. M. Després, in replying, said that he never knew a patient to complain of it. M. Le Dentu said that M. Auger employs the injection of two drops of chloride of zinc in the deliquescent state into the cyst without previously evacuating it. This treatment always succeeds; there follows a sharp inflammatory reaction, but it is by no means dangerous. The inflammation subsides in five or six days, and at the end of ten days the cure is complete. For small ranulæ one drop of the liquid suffices, and if the cyst is very voluminous it is preferable to draw off a little of the contents before introducing the chloride of zinc. M. Gilette could not agree with M. Le Dentu in considering that chloride of zinc was not attended with danger and that it was always successful. He had seen M. Auger at the Hôpital Beaujon inject three drops and the pain was so intense that the patient tried to jump out of the window; and after all the cyst returned and was eventually excised.—*Medical Press and Circular.*

Dry Dressings with Powdered Salicylic Acid.—The good results obtained in the treatment of ulcers, wounds, etc., by the application of powdered iodoform, have led to a similar series of experiments with powdered salicylic acid at the surgical clinic of Erlangen. The method, as described by Schmid, is very simple. The wound is first carefully cleansed and disinfected with a five per cent. solution of carbolic acid. Where practicable, sutures are applied and the closed wound covered with a layer of very finely pulverized salicylic acid, one-half centimetre high and sufficiently extensive to overlay the wound one centimetre in every direction. Excavated wounds, after being cleansed, are carefully plugged with acid, and then likewise powdered, and the whole protected by a piece of antiseptic gauze or salicylated cotton. Wounds thus treated secrete only a small amount of wound-serum, which coalesces with the dressing so as to form an adherent crust. No smell of decomposition manifests itself: on the contrary, several wounds of long standing were thoroughly deodorized by this method, after ordinary Listerian dressings had been ineffectually employed. At the same time the temperature of the patient, if elevated, sinks as much as 2° C. or more. As the dressing appears to promote a luxuriant growth of granulations, it is more applicable to excavated than to surface wounds.—*Deutsche Zeitschrift f. Chirurgie*, Bd. xiv.; *New York Medical Record.*

The Treatment of Neuromata by Enucleation.—Mr. E. Downes, in the *Lancet*, April, 1881, suggests that in many cases of nerve-tumor the morbid mass may be shelled out by a longitudinal incision, instead of excising the growth with a portion of the nerve itself, or amputating the limb, as in some cases has been done. Three cases are related in which this mode of treatment was successful, the nerve-fibres completely surrounding the tumors, which lay in the centre almost entirely unconnected with the nerve itself. In one case, in which a neuroma of the median nerve was treated by excising the mass with the included portion of the nerve, a large number of smaller neuromata spontaneously disappeared after the larger one was thus removed. [Prof. Kosinski narrated a somewhat similar case (*Medical Times and Gazette*, November, 1874, p. 558); here, after a neuroma of the small sciatic had been excised, a large number of similar tumors spontaneously disappeared.] —*London Medical Record*, June 15, 1881.

Tuberculosis of the Mammary Gland.—An authentic case of this exceedingly rare affection is reported by Le Dentu, in the *Revue de Chirurgie*, No. 1, 1881. The patient, a girl of twenty-two years, who had suffered from scrofulous diseases in her youth, was treated in February, 1879, for a chronic abscess of the left breast, which healed after incision and drainage. One year later the same breast became uniformly enlarged, and had to be removed by amputation. On examination it was found permeated with abscesses lined with fungous masses, and containing tubercles possessing all the characteristics of this neoplasm.—*New York Medical Record.*

Resection of Large Trunk-Veins.—Pilzer opposes strongly (*Deutsch. Zeitschr. für Chir.*, Band xiv. Heft 21) the prejudice against ligature of large veins, citing recently-recorded cases to prove that the fear of pyæmia is groundless. He gives in detail six cases from the Heidelberg surgical clinic. In all six, malignant disease was present; and the internal jugular vein was resected in four cases, both internal jugulars in another, and the femoral vein in the sixth. All the cases recovered. Resection of the vein is much to be preferred to the dissection of it out of the tumor, with the great risk of recurrence of the tumor from fragments left on the vein.—*British Medical Journal*, May 7, 1881.

Trigeminal Neuralgia.—Dr. Seifert (*Berlin. Klin. Wochensch.*, 1881, No. 11) publishes three cases of trigeminal neuralgia in which he successfully employed compression of the carotid, as recommended by Gerhart. The compression was made to last from fifteen seconds to one and a half minutes, and repeated as often as the pain was interrupted, while arsenic and quinine were likewise administered. Gradually the intervals were lengthened.—*London Medical Record.*

MISCELLANY.

Our Medical Literature.—At the last International Congress Dr. Billings, of Washington, was honored by a very considerable

audience to listen to his address on "Our Medical Literature," and fully rewarded were all who managed to escape the pomps and vanities elsewhere, or the labors of the Sections, by hearing one of the most able, exhaustive, and certainly the most racy oration of the Congress. Of course the subject was attractive and capable of profound elaboration, and, as editor of those magnificent volumes now being compiled for the Surgeon-General's Office at Washington, Dr. Billings was *facile princeps*, and succeeded most admirably.

He estimated that one-thirtieth part of the world's literature belongs to medicine and the allied sciences, medical literature owning 120,000 volumes and twice as many pamphlets, with a yearly increase of 1500 volumes and 2500 pamphlets. Of the 180,000 educated medical men scattered over the world, 11,600 contribute to this mass of literature, the United States having the larger actual percentage, and England being outdone by the Germans and French, as well as by the Americans. Reckoning, however, the number of physicians in each country, France shows the greatest and the United States the smallest proportion. Referring to the short lives of most new medical journals, he adduced figures to show that in 1880 there were 24 deaths and 78 births. But Great Britain (John-Bullish even here) "is the most stable of all;" her old journals being on very secure foundations, and new ones not often started.

On the subject of general medical literature he remarked that in days of old, when the profession of medicine, or of a single medical specialty, was an inheritance in certain families, a large part of their knowledge and the efficiency of their remedies was thought to depend upon these being kept a profound mystery. Among the precepts of magic there was no more significant one than that which declared that the communication of the formula destroyed its power, and that hence attempts to reveal the secret must always fail. We have changed all that. Every physician hastens to publish his discoveries and special knowledge, and a good many do the same by that which is not special, or which is not knowledge. For the individual in a degree—for the nation or the race in a much greater degree—the literature produced is the most enduring memorial. And thus in our great medical libraries each of the folios or quaint little black-letter pamphlets which mark the first two centuries of printing, or of the cheap and dirty volumes of more modern days with their scrofulous paper and abominable typography, represents to a great extent the life of one of our profession and the fruit of his labors, and it is by the fruit that we know him. The learned orator concluded his address with a trite verse from the Talmud, which reminds one of the first aphorism of Hippocrates: "The day is short, and the work is great; the reward is also great, and the master presses. It is not incumbent on thee to complete the work, but thou must not therefore cease from it."—*Medical Press and Circular.*

"Pain-Killers."—Prof. A. B. Prescott, of the University of Michigan, in an interesting paper on "Nostrums," read at a State sanitary convention, and since printed in *The Physician and Surgeon*, thus refers to one of the more harmless kinds of these quack preparations, the "Pain-Killers":

Few of them are wholly inert, and most of them have a transient stimulant effect. Of *eight* of them subjected to analysis, six were found to contain the ordinary spirit of camphor, which every thoughtful mother keeps in the house; three contained ammonia, such as any hartshorn-bottle would furnish; four were charged with red pepper; all had some alcohol; oil of sassafras was found in four of them, oil of turpentine in two of them, tincture of guaiac in two, chloroform in one, and myrrh in one. One of the most successful contained in a half-dollar bottle one and a half fluidounces of soap liniment, with one-half fluidounce each of capsicum tincture, ammonia water, and alcohol,—in all, four articles of the United States Pharmacopœia. One that was sold at a dollar for a four-ounce bottle, by a Chinese doctor who had studied many years in the Celestial Kingdom, and who visited the towns of Michigan in a gorgeous car drawn by four horses, with a company of musicians and a lecturer, consisted of camphor spirit, lavender compound spirit, ammonia water, sassafras oil, and alcohol. One made and sold in Germany as Nature's Own Cure, a sure relief for one hundred and sixty-six different diseases, consists of red-pepper tincture, ammonia, and alcohol. Another, noticed since grouping the eight articles, is a Five-Minute Fragrant Pain Cure, that will quiet every ache within five minutes by an exact timepiece. It is a mixture of ether, glycerin, common salt, and water. A Golden Wonder, or Seven Seals, for all the ills liable to occur in this life, is a mixture of ether, chloroform, camphor, peppermint oil, red pepper, and alcohol. Nearly all of these articles are directed to be taken internally, as well as applied externally. Now, almost every person would have some judgment as to how much of ammonia, or turpentine, or camphor, or ether, or strong alcohol, it would be safe to take at once, if to be taken at all, in seeking relief from a violent pain; but what judgment can anybody have as to a safe quantity of such talismanic articles as "Ready Relief," "Wizard Oil," or "Magic Master of Misery"? —*Boston Journal of Chemistry.*

An Anæsthetic Car.—A correspondent of the *British Medical Journal* gives the following description of Bert's anæsthetic car for giving nitrous oxide and compressed air. "I was at the St. Louis Hospital one morning;

the car was there, and some operations were to be done in it. We—the patient, doctor, and his students—went into the car; the door, air-tight, was closed, and air forced into the car; in a few minutes my ears began to feel strange, and I was told to swallow, yawn, and blow my nose, which I did every few minutes, and so made the pressure equal on both sides of the drums of my ears. The patient laid himself down on the operating-table, and the anæsthetic agent was given him. He took it very quietly, did not struggle, and was soon insensible. Whilst he was unconscious, an epithelioma was removed from his lower lip; after the wound was sewn up, the compressed air was allowed to escape; the patient got up from the table, walked out of the car, and lay down on the grass; he complained of no headache nor nausea, but said he felt just as usual. We also were glad to escape from the car, on account of the heat, which was very intense. During the operation all the assistants and the surgeons pulled off their coats and waistcoats, and yet they perspired very freely. The car is on wheels, and is carried about from hospital to hospital: the hospitals being under government, the car is a public one, and is taken all over Paris." —*New York Medical Record.*

ZOEDONE.—The English chemists have lately been giving a good deal of attention to the making of "temperance" beverages, among which *zoedone* is one of the most popular. This is an effervescing phosphorated ferruginous water, which was invented and patented some three years ago by David Johnson, F.C.S. It is described as a most pleasant and refreshing drink, in which the peculiar iron taste is said to be very successfully masked by a peculiar flavoring syrup, which alone is kept a secret. The quantities of the active ingredients in each small champagne-bottle are given by the patentee as follows:

Calcii phosphas, grs. $2\frac{1}{2}$;
Ferri phosphas, gr. 1;
Potassii phosphas, gr. $\frac{1}{5}$;
Sodii phosphas, gr. $\frac{1}{12}$.

—*Boston Journal of Chemistry.*

THE FASHIONABLE BEVERAGES.—Dr. Myrtle, in a paper on gout (*Medical Press and Circular*), says, "In conclusion, let me say a few words on a new tap opened for the sole benefit of the thirsty public. I shall be curious to watch what may happen during the next ten years after we have got our systems fairly saturated with those marvellous drinks which Limited Liability introduces to us, those beautiful, sparkling, refreshing, and invigorating beverages at 5*s.* 6*d.* per dozen, more agreeable than champagne, and, in my opinion, a hundredfold more injurious. In those trashy compounds I believe we shall find a new source of dyspeptic torments and an additional factor of gout. I once was bullied into tasting some stuff with a fine-sounding name and gorgeous get-up: from the little sip I took, I can honestly advise every one who has any respect for his inside to avoid all drinks whose names, whatever their beginnings, end with the letters INE, ONE, or ADE, and stand by the good old-fashioned beverages of our youth. If stimulants are to be taken,—and I believe to a certain extent they are necessary,—you will find sound beer, good wine, and old spirit more wholesome, more suitable to the climatic conditions under which we live, than any other, and not one whit more gouty."

NOTES AND QUERIES.

A MODIFICATION OF MARTIN'S RUBBER BANDAGE.

J. J. L. applied to me July 20 for treatment for a large varicose ulcer on the internal aspect of the right leg. On my proposing to apply a Martin's bandage, he demurred, on the ground that he had tried one formerly,—that, owing to the confinement of the perspiration, his leg was in a constant water-bath, and the heat, itching, and pain were unendurable. I had before felt the force of this objection, and have no doubt but that this has been the greatest obstacle to the successful employment of this bandage in a large class of cases.

It occurred to me that the desideratum—ventilation—might be attained by perforating the bandage without sacrificing in other respects its usefulness. In pursuance of this plan, I procured an ordinary shoe-punch and riddled the bandage with holes,—about nine to the square inch. By punching three or four thicknesses at once, the labor was considerably facilitated.

This bandage was applied with entire success. Ventilation is perfect. The leg feels cool, dry, and comfortable, and at this date the ulcer has almost entirely healed.

JOHN S. LEWIS, M.D.

DUBUQUE, IOWA, August 17, 1881.

TRI-STATE MEDICAL SOCIETY.

OFFICE OF SECRETARY, MITCHELL, IND., August 18, 1881.

THE Seventh Annual Meeting of the Indiana, Illinois, and Kentucky Tri-State Medical Society will be held in the city of St. Louis, Mo., Tuesday, Wednesday, and Thursday, October 25, 26, and 27, 1881.

The Profession of the "Mississippi Valley" are cordially invited to attend.

G. W. BURTON, Secretary.

Medical journals please notice.

DR. H. C. WOOD has returned from Europe, and has removed his residence to 1925 Chestnut Street.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY FROM SEPTEMBER 4 TO SEPTEMBER 17, 1881.

BROWN, P. R., CAPTAIN AND ASSISTANT-SURGEON.—Granted leave of absence for one month. S. O. 210, A.G.O., September 13, 1881.

SKINNER, J. O., CAPTAIN AND ASSISTANT-SURGEON.—To proceed to Fort Verde, A.T., and report to the Post-Commander for duty as Post-Surgeon. S. O. 101, Department of Arizona, September 2, 1881.

REED, WALTER, CAPTAIN AND ASSISTANT-SURGEON.—Assigned to duty with Light Battery "A," Second Artillery, ordered to leave Washington Barracks, D.C., on September 20, and march to Yorktown, Va. S. O. 165, Department of the East, September 16, 1881.

BURTON, H. G., CAPTAIN AND ASSISTANT-SURGEON.—To accompany Light Battery "C," Third Artillery, as Medical Officer, on its march from Fort Hamilton, N.Y., to Yorktown, Va., *via* Trenton, N.J., Philadelphia and Columbia, Pa., Baltimore, Md., and Washington, D.C., and remain with it until further orders. S.O. 163, Department of the East, September 14, 1881.

INDEX.

Aaronson, Lizzie, case of, 591.
